

WELCOME

The IEEE Magnetics Society Conference, “Intermag Europe 2008”, will be held from Sunday, May 4th, until Thursday, May 8th, at the Palacio Municipal de Congresos in Madrid, Spain. Intermag is the premier conference on applied magnetism and related technologies. Members of the international scientific and engineering communities interested in recent developments in these topics are invited to attend the conference.

We have planned an exciting and informative set of symposia, tutorial sessions and invited talks, regular oral and poster presentations and technical exhibitions reviewing the latest developments in this field.

Intermag Europe 2008 is a unique event. We are delighted to announce that this year’s Nobel Laureates in Physics, Prof. Albert Fert and Prof. Peter Grünberg have confirmed their attendance at the 2008 Intermag Conference. A GMR Nobel Celebration has been arranged for the evening on Monday May 5th, where Prof. Grünberg will deliver a lecture on “From Spin Waves to Giant Magnetoresistance and Beyond” and Prof. Fert will lecture on “Emerging Directions in Spintronics”. Other technical events and celebrations in recognition of the Nobel Prize for the discovery of GMR are also planned. We hope that members of the IEEE Magnetics Society and researchers with interests in the field will join us for this special occasion.

Finally we also hope you will enjoy visiting Madrid and experiencing Spanish culture. On behalf of the Management Committee of Intermag Europe 2008, we look forward to seeing you in Madrid.

Manuel Vázquez

Ron Indeck

General Chairmen

LOCATION

Madrid is the cosmopolitan capital city of Spain. It is the home of the administration of the Spanish government and Parliament as well as the residence of the monarch. It is one of the most important cities in Spain in the financial and industrial sectors. Madrid is a cosmopolitan and multi-ethnic city with more than 4 million inhabitants and is characterised by intense cultural and artistic activities as well as a vibrant nightlife.

Madrid is also a centre for science and technology. In Madrid there are 6 public and 9 private universities and about 30,000 students study science and technology. More than 50 research centers in different branches and institutes provide a dynamic scientific community. For more information about science and technology in Madrid, go to www.madrimasde.org/English/default.asp

Intermag Europe 2008 will be held at the Palacio Municipal de Congresos, located in the “Campo de las Naciones”, the new financial hub of the city, which is well connected with the centre and only five minutes from Barajas Airport.

Further information about Madrid can be found on the web at: www.esmadrid.es or www.turismomadrid.es.

WEATHER

Springtime is the nicest season of the year in Madrid. The days are long and the temperatures pleasant, though it can cool down at night. The average temperature in May is around 16° C with a maximum of 22° C and minimum of 9° C. Rain is not uncommon in spring.

TRANSPORTATION IN MADRID

Underground/Subway:  The lines are differentiated by colour and are numbered from 1 to 13. Tickets can be purchased in every station from ticket offices or automated machines. Single tickets cost 1 €. Metrobus, which is a 10 journey travel card valid for underground and buses, costs 6.70 €. The underground/subway runs from 6:00 am to 1:30 am.

Line 8 (pink line) goes to the station “Campo de las Naciones” where the conference venue is located.

City Buses: The city buses are a good alternative to the subway. Bus single tickets can be paid directly to bus driver. The buses run from 6:00 am to 11:00 pm. Night buses (called “buhos”) run less frequently. The price is the same, 1 €. Traffic jams in Madrid are frequent

For more information please visit the following website: <http://www.emtmadrid.es/>

Tourist Travel Pass: A Tourist Travel Pass can be used on all public transport in the city as many times as required within its period of validity. There are five types of pass valid for 1 to 7 days. The card can be purchased at all stations in the subway network, at the Centro de Atención al Viajero (Passenger Assistance Centre), at both airport stations (line 8) and at Tourist Offices.

Area A, comprising the services of the Metro and EMT de Madrid (buses).

TOURIST TRANSPORT CARD (PRICE IN EURO)					
A Area					
	1 day	2 days	3 days	5 days	7 days
Adult	4.00	7.20	9.60	15.00	20.80

Madrid Public Transport Information:

Please visit www.ctm-madrid.es

You can also find an underground map at:
www.metromadrid.es/acc_resources/pdfs/Plano_Metro_2007.pdf

Taxis: Taxis in Madrid are white and are distinguished with a diagonal red band on the front doors. A green light on top of the taxi indicates if it is available. The taxi should always charge by the taxi-meter that runs according to distance covered, the urban area, the day of the week (higher fares on holidays), and the pickup point (higher fares for pickups in bus stations, train stations and airport). Passengers are never required to pay additional fares for luggage if there is enough space in the boot. Additional fares are shown on information signs on the back windows of the taxi.

Car Rental: Car rental is not recommended to get around Madrid due the traffic. Parking in Madrid is expensive and always difficult. A large part of the tourist area is not accessible by car.

ACCESS TO MADRID CENTRE FROM MADRID AIRPORT

By Underground/Subway

- From Terminals 1, 2 and 3 (T1, T2 and T3): Connection to underground (metro) line 8, the underground station is called “Aeropuerto T1-T2-T3”.
- From Terminal 4 (T4): Connection to underground line 8, the underground station is called “Aeropuerto T4”.

The metro fare to downtown Madrid is 2 Euros but involves a change of train.

By Bus: Number 200 to “Avenida de America” bus station. There you can find connection to underground lines: 4, 6, 7 and 9.

By Taxi: The approximate cost from the airport to the city centre is around 30 €.

ACCESS TO INTERMAG 2008 VENUE

Venue: Palacio Municipal de Congresos,
Avenida de la Capital de España Madrid, 7, 28042 Madrid.

Underground/Subway:  Line 8, Station “Campo de las Naciones”

Access Map: Please visit
http://www.madridespaciosycongresos.es/palacio/situacion_i.cfm

HOTEL ACCOMMODATION

Participants interested in making a hotel reservation, should check the accommodation offer on the website and follow the procedure. A hotel confirmation showing the amount received will be issued and sent as soon as the payment is received. For further information about hotel reservations please contact sureta@siasa.es.

ACCOMMODATION FOR STUDENTS

<http://www.student-accommodation-madrid.com/>
<http://www.madridflatmate.com/>

LUNCH, TAPAS AND DINNER

Spain has a different dining schedule than some other countries. Lunchtime typically starts at 1:30 pm and can finish as late as 4:00 pm. Dinner starts after 9:00 pm and many restaurants are not open until this time.

One of Madrid's main attractions is its great number of bars and taverns where you are able to relax after a busy day, enjoy a glass of wine or a beer accompanied by a tasty 'tapa'. "Tapeo" has existed as a pleasant and healthy custom in Spain since the 13th century, when the Castillian King Alphonse X ("the Wise") forced bartenders to serve something to eat when customers ordered wine. Today tapas are small snacks between meals, though on many occasions tapas can substitute for meals.

CONFERENCE REGISTRATION

Advance registration fees can be paid in € or US\$. The advanced registration deadline is March 31st 2008. Advanced registration and full payment must be received before March 31st. Registration payments received after this date or on-site will be at the higher rates.

Please note that the IEEE Magnetics Society has provided a special discount to the registration fee for Society members wishing to attend InterMag 2008. This \$100 discount is in addition to the usual IEEE member discount. Participants are advised to join the Society on-line at www.intermagconference.com/intermag2008. Those registering on-site can join the Society at registration to take advantage of the discount.

REGISTRATION FEES	Advanced Registration Before 31 March '08	On-Site Registration
IEEE Magn. Soc. Members	390 €/ 570 \$	470 €
IEEE Members	460 €/ 670 \$	540 €
Non-IEEE Members	550 €/ 800 \$	650 €
Students IEEE Magn. Soc. Members Unemployed Retiree	175 €/ 255 \$	195 €
Students IEEE Members Unemployed Retiree	230 €/ 335 \$	250 €
Students non-IEEE Members Unemployed Retiree	275 €/ 400 \$	300 €

Advanced registration via the web is the most convenient way to register and is highly recommended. On the conference website you will find links to register on-line or to download a PDF file. www.intermagconference.com/intermag2008

The registration fee includes:

- Access to all Scientific Sessions
- Digest CD
- Morning coffee
- Evening Bierstube
- GMR Nobel Celebration
- Awards Ceremony
- Plenary Lecture
- Magnetics Society Reception

All conference attendees including invited speakers must pay the appropriate registration fee.

All attendees will be required to wear InterMag 2008 name badges at all times.

The use of cameras, videotaping and/or recording devices in the technical sessions is prohibited.

On-site Registration:

Registration on-site can be paid only in Euros. Payment in Euros can be made in cash or by MasterCard, Visa or American Express credit cards only.

The Conference Registration Desk, located in the main lobby of the Palacio Municipal de Congressos, will be open during the following hours:

- Sunday May 4th. 4:00 pm - 7:00 pm
- Monday May 5th 8:00 am - 6:00 pm
- Tuesday May 6th 8:30 am - 6:00 pm
- Wednesday May 7th 8:30 am - 6:00 pm

Cancellation Policy:

Cancellations of registrations paid in Euros must be received by e-mail at sureta@siasa.es or fax (34 91458 10 88). Payments will be refunded less a 50 € service charge before March 31st. After March 31st, cancellations will be accepted but not refunded. Substitutions may be made prior to April 20th.

Cancellation of registrations paid in US\$ must be received in writing at YesEvents:

InterMag 2008 Conference c/o YesEvents
P.O. Box 32862
Baltimore, MD 21282 USA

Payments will be refunded less a \$75.00 service charge before March 31st. After 31st, cancellations will be accepted but not refunded. Substitutions may be made prior to April 20th.

VISA REQUIREMENTS

EU citizens need only their national identity card or passport to enter Spain. Citizens of the United States, Australia, Canada, Japan, South Korea and Singapore do not need a visa to visit Spain for up to 90 days.

Citizens from other countries should contact their local Spanish Embassy or Consulate for details regarding visa applications. Please contact the embassy or consulate as soon as possible in order to determinate your particular visa requirements.

For additional information please visit:

www.mae.es/en/webembajadasconsulados/

If you need a personal letter of invitation to obtain a visa, please contact visaintermag2008@icmm.csic.es, providing your full name, complete mailing address and reference number of the submitted digest. An original letter will be sent to you by post.

Please note that a letter of invitation will be provided to assist delegates obtaining visa or permission to attend the conference and should not be considered as an official invitation covering the registration fee or other expenses. Applications for invitation letters must be received by April 1st 2008.

Citizens from all countries must carry a valid identity card or passport at all times.

ORAL PRESENTATION

Invited talks are a 25 minutes presentation with 5 minutes discussion. Contributed talks are 12 minutes plus 3 minutes discussion. Session Chairs will keep all sessions strictly to time to allow delegates to move between sessions.

All accepted oral presentations are to be made using LCD projectors connected to the author's personal computer. Authors are advised to bring as USB flash memory as a back-up. No alternative presentation facilities will be provided.

Only standard PC-style VGA connections to the LCD projector will be supplied. You must supply any adaptor required for your computer. Macintosh users must make sure that "mirroring" is activated.

SPEAKER PRACTICE ROOM

Speakers may use the Luxemburgo Room on the first floor to practice their presentations. Audiovisual equipment will be available for authors to use. This room will be open as follows:

Monday	8:00 am – 6:30 pm
Tuesday	8:30 am – 6:30 pm
Wednesday	8:30 am – 6:30 pm
Thursday	8:30 am – 1:00 pm

A booking sheet is available on the practice room door allowing users to book the room. Bookings are allowed for 20 minute periods only.

POSTER SESSIONS

Poster presentations will consist of visual materials about the work presented on a designated board. An author must be available to answer questions during a significant part of the session. An author should be present for the first and last 30 minutes of morning sessions and the last 60 minutes of afternoon sessions. The conference provides a small sign designating the paper number to be posted on each board. Mounting materials will be provided.

For the first time Intermag 2008 will include invited poster presentations. There will be one invited poster in each half day session. Invited posters will be allocated 2 poster boards.

Papers related to posters where the authors did not attend the conference or were not available to discuss their work will not be published.

Poster Area: Polivalente Room on the 3rd floor of the conference venue.

Posters should be displayed from 9:00 am – 1:00 pm or from 2:30 pm – 6:30 pm

Poster board size is 95cm high by 130cm wide. Note this is landscape style.

Authors should set up their posters at least 15 minutes before the session starts. Presenters must be by their posters from 9:00 am to 9:30 am and from 12:30 pm to 1:00 pm for the morning session and from 5:30 pm to 6:30 pm for the afternoon session.

Authors are reminded to remove their posters promptly at the end of their session. Posters not removed will be discarded.

PUBLICATIONS ROOM

The Publication Room will be located in the Dublin Room on the second floor. The status of all papers will be displayed and authors should check periodically on their papers. Authors may leave messages for the editor for their paper. Each editor will post a notice of times at which he/she can be found in the publication room. Editors will respond to messages and questions as promptly as possible. This room will be open as follows:

Monday to Wednesday:	9:00 am – 6:00 pm
Thursday:	9:00 am – 4:00 pm

Session Chairs are requested to visit the editor for their session to support the completion of the reviewing process for all papers in their session.

TUTORIAL

The IEEE Magnetics Society Education Committee has organized a tutorial on "Multiferroics". The tutorial will be at a level for a novice in the subject but should be of interest to specialists and non-specialists.

The tutorial program is:

Session Chair:	J.W. Harrell
Date:	Sunday, May 4th, 2008
Time:	5:00 pm – 7:00 pm
Room:	Auditorio A

Speakers:

James Scott, Cambridge (UK)
Wilfrid Prellier, CRISMAT (France)
Gopalan Srinivasa, Oakland University (USA)

GMR NOBEL CELEBRATION

We are delighted to announce that this year's Nobel Laureates in Physics, Professor Albert Fert and Professor Peter Grünberg have confirmed their attendance at the 2008 InterMag Conference in Madrid. A GMR Nobel Celebration (session YA) has been arranged for the evening on Monday, May 5th. This special session will be preceded by a symposium on The Importance of GMR (session BA).

Session YA GMR Nobel Celebration

5:10 pm Monday May 5th: Auditorio A

Session chair: Manuel Vazquez,
General Chair InterMag Europe 2008

- 5:10 pm Opening Remarks
 Prof. Carl Patton
 IEEE Magnetism Society President
- 5:20 pm “From Spin Waves to Giant Magneto-resistance
 and Beyond”
 Prof Peter Grünberg, NL
 Forschungszentrum Jülich
- 6:00 pm “Emerging Directions in Spintronics”
 Prof Albert Fert, NL
 CNRS, Université Paris-Sud
- 6:40 pm Recognition from the IEEE
 Lew Terman
 President IEEE
- 6:50 pm Closing Remarks
 Prof. Manuel Vázquez
 Conference Chair InterMag 2008
- 7:15 pm Celebratory Reception, Polivalente Room
 Toast to Nobel Laureates
 Prof. F. Marcellán (Secretary of State of Science
 and Technology, MEC)
 Prof. C. Martínez (President of the Spanish National Research Council, CSIC)
- 7:45 pm Close

IEEE MAGNETICS SOCIETY ANNUAL GENERAL MEETING

This meeting is open to all InterMag participants. Please come to learn what the IEEE Magnetism Society is doing and the benefits of joining the Society. The meeting will be held on Tuesday, May 6th, at 6:30 pm - 7:30 pm in Auditorio A. Please sit towards the front of the Auditorium.

AWARDS AND PLENARY SESSION

4:40 pm Wednesday May 7th: Auditorio A
Session Chair: Bruce Gurney

IEEE Magnetism Society Awards

IEEE Reynold B. Johnson Information Storage Device Award

Prof. Stanley Charap
Professor of Electrical and Computer Engineering, Carnegie-Melon University, Emeritus

The IEEE Daniel E. Noble Award

Dr. James M. Daughton (NVE Corporation)
Dr. Stuart Parkin (IBM, San Jose)
Dr. Saied Tehrani (Freescale Semiconductor)

The Magnetism Society Achievement Award

Prof. Jack H. Judy
Professor of Electrical Engineering, University of Minnesota, Emeritus

Newly Elected Fellows of the IEEE

Roy W. Chantrell, University of York
Vincent G. Harris, Northeastern University
Jinliang He, Tsinghua University
Thomas D. Howell, San Jose State University
Hiroaki Muraoka, Tohoku University
Lalita Udpa, Michigan State University
John Wikswo, Vanderbilt University
Jian-Gang Zhu, Carnegie Mellon University

2007 Magnetism Society Distinguished Lecturers

Matthias Bode, Argonne National Lab
Vincent Harris, Northeastern University
Sara Majetich, Carnegie Mellon University
Takao Suzuki, Toyota Technical Institute

IEEE Magnetics Society Best Student Paper Award

Following the establishment of this prestigious prize by the IEEE Magnetics Society in 2008, the selection of the five finalists has been made after a full review of all students entering the competition by the Programme Committee Co-Chairs for InterMag 2008. This selection has been based solely on the likely quality/impact of the work. The five finalists will receive a cash award from the Magnetics Society as well as recognition for their achievement.

The eventual winner of the award will be selected by a transnational panel of four young scientists who have recently completed their PhDs and who will visit each presentation, whether poster or oral, to assess the papers according to the following criteria:

1. The quality/impact of the work
2. The student contribution and involvement in the work
3. The quality of the presentation by the student.

Each criteria will make an equal contribution to the assessment. The assessment of the panel will be overseen by Prof. J W Harrell, the Chairman of the IEEE Magnetics Society Education Committee and Dr Bruce Gurney, the Chairman of the Awards Committee. The award will be made to the student achieving the highest overall ranking in the three criteria.

Please note that students associated in any way with any persons involved in the selection of the finalists or the eventual winner have been declared ineligible in the competition.

Finalist: Pedram Khalili Amiri Paper: CV – 01

Title: Integrated on-chip microstrip lines
with Co-Ta-Zr magnetic films

P. K. Amiri, B. Rejaei, Y. Zhuang, M. Vroubel,
D. Lee, S. Wang & J. Burghartz (Netherlands)

Finalist: Karen Livesey Paper: HC – 02

Title: Nonlinear processes during switching
of a thin Permalloy film in different geometries

K. Livesey, H. Nembach, M. Kostylev, P. Martin-Pimentel, S. Hermsdoerfer, B. Leven, R. Stamps, B. Hille-
brands (Australia)

Finalist: Hiroyuki Tomita Paper: AA – 04

Title: Real Time Measurements of Spin-Transfer Switching
in CoFeB/MgO/CoFeB Magnetic Tunnel Junctions

H. Tomita, K. Konishi, T. Nozaki, M. Shiraishi, H. Kubota,
A. Fukushima, S. Yuasa, Y. Suzuki (Japan)

Finalist: Takayuki Ishikawa Paper: AC – 07

Title: Spin-dependent tunneling conductance in fully epitaxial Co₂MnSi/MgO/Co₂MnSi tunnel junctions

T. Ishikawa, N. Itabashi, K. Matsuda, T. Uemura,
M. Yamamoto (Japan)

Finalist: Benoit Georges Paper: CB – 06

Title: Phase locking of a Spin Transfer Oscillator
to an external microwave current : a milestone
for the synchronization of a large assembly of STOs

B. Georges, J. Grollier, M. Darques, V. Cros,
C. Deranlot, G. Faini, A. Fert (France)

In addition, the 2008 Student Travel Grants will be presented.

Plenary Lecture

Session Chair: Josef Fidler

Following the awards ceremony at approximately 5.40 pm on Wednesday, May 7th the InterMag Plenary lecture will be presented. The speaker is Prof. Ludwig Schultz of IFW Dresden whose title will be:

“Riding on Magnetic Fields - Macroscopic Interaction
of Ferromagnetic and Superconducting Permanent Magnets”

Abstract:

Different concepts for magnetic levitation are discussed. The conventional system is the Transrapid now running between Shanghai Airport and the city centre. Our approach is a passive superconducting magnetically levitated system using bulk superconductors cooled to 77 K. At low temperatures, superconductors can freeze in a magnetic field of any configuration. Hence they act as permanent magnets but with a magnetic remanence, which is, for YBaCuO material, far larger than that of ferromagnetic permanent magnets. The ability to freeze in a magnetic field can be used for completely new applications. This will be experimentally demonstrated for different types of superconducting magnetically levitated trains, which can either be in an upright or a hanging position or, moving along a wall without any mechanical contact. With regard to scaling-up, the SupraTrans project will be presented.

Biography:

Ludwig Schultz studied physics at the University of Goettingen and received his Ph.D. in 1976 with a thesis on flux pinning in superconductors. He continued as a research assistant at the Institute of Metal Physics of the University of Goettingen and as a postdoc at IBM Thomas J. Watson Research Center in Yorktown Heights. In 1980 he joined Siemens Research Labs at Erlangen. In 1993 he accepted a call to become a full professor at TU Dresden and Director of the Institute of Metallic Materials at the Leibniz Institute of Solid State and Materials Research (IFW) Dresden. On April 1, 2008 he will be promoted to be the Scientific Director of this Institute. His main activities concern permanent magnets, CMR materials, magnetic thin films, magnetic shape memory alloys, superconducting materials and superconducting levitation systems. He authored or co-authored more than 650 publications with more than 13,000 citations, filed 65 patents and founded 2 companies: Evico and Evico Magnetics.

Magnetics Society Reception

Invitation: Prof. Manuel Vázquez

General Chair InterMag Europe 2008

Following the Plenary lecture a Magnetics Society reception will be held in the Polivalente Room for all participants at InterMag Europe 2008. This reception has been provided by special funding from the IEEE Magnetics Society.

BIERSTUBE AND COFFEE

A coffee service will be available Monday through Thursday mornings in the poster and exhibition area in Polivalente Room located on the third floor, from 9:00 am – 10:00 am.

On Tuesday evening, the Bierstube will be held in the Polivalente Room, from 6:00 pm - 7:00 pm. During registration on Sunday May 4th the Bierstube will be held in the foyer of the conference centre.

EXHIBITION

The Exhibition will be located in the Polivalente Room. This large space will allow us to accommodate the exhibition, poster area and catering service for morning coffee and afternoon bierstube.

Exhibition hours:

• Monday May 5th	9:00 am - 7:00 pm
• Tuesday May 6th	9:00 am - 7:00 pm
• Wednesday May 7th	9:00 am - 7:00 pm
• Thursday May 8th	9:00 am - Noon

IEEE MAGNETICS SOCIETY MEMBERSHIP

If you are not already a member of the IEEE Magnetics Society we advise you to join and take advantage of the special discount for this conference. The difference between the Magnetic Society member rate and the non-member rate is significantly more than the membership fee. Join now by going on-line at www.ieeemagnetics.org and follow the links. A membership desk will be available at registration but significant delays may occur.

Through the IEEE Magnetics Society you get unlimited access to all issues of the IEEE Transactions on Magnetics since the journal's inception in 1969 with unlimited downloads. This includes all Intermag Proceedings as well as other topical conferences published in the Transactions. Membership also includes a CD-ROM copy of the Transactions each year. By joining, you become a part of the world's largest and best known organization in magnetics. You also gain access to local chapter events, technical activities and student sponsorship for conference travel.

STUDENT TRAVEL GRANTS

The IEEE Magnetic Society will award travel grants of up to \$1000 each to a limited number of students who wish to attend Intermag Europe 2008. These grants are intended to partially offset travel costs. Support is for current graduate students only. Post-doctoral workers and undergraduate students are ineligible. Students who have previously received travel support from the Magnetics Society are also ineligible.

Preference will be given to Student Members of the Magnetics Society. Preference will also be given to students nearing completion of their studies and presenting conference papers. The student's supervisor must also be a member of the Magnetics Society. The student's supervisor must write a brief letter of endorsement for the applicant. A second endorsement from a full member of the IEEE Magnetic Society is also required.

Shortly after the conference, grant recipients must submit a short account of their experience for possible inclusion in the IEEE Magnetic Society Newsletter. Forms and instructions for applicants are available at:

www.intermagconference.com/intermag2008.

Applications and all letters of endorsement must be submitted before March 7th 2008. Inquiries should be sent to the Student Travel Grants Co-Coordinator:

M. J. Carey, Hitachi GST, San Jose, CA (matthew.carey@hitachigst.com).

Students wishing to apply should also visit the IEEE Magnetics Society website at: www.ieee.magnetics.org.

	Session	Session Title	Location
Sunday Tutorial 5:00 pm – 7:00 pm	ZA	IEEE Magnetics Society Education Committee Tutorial: Multiferroics	Auditorio A

Monday Oral Sessions 9:30 am – 12:30 pm	AA AB AC AD AE AF AG AH	Spin-Torque Switching Domain Walls in Nanowires Magnetic Tunnel Junctions - I Thin Films: Interface and Transport Properties Heat and Microwave Assisted Recording Characterization and Measurement Techniques - I Transformers and Inductors - I Magnetoeimpedance	Auditorio A Madrid Roma Paris Londres Berlin Amsterdam Caracas
--	--	--	---

Monday Poster Sessions 9:00 am – 1:00 pm	AL AM AN AO AP AQ AR AS AT AU AV	Motors and Actuators - I Magnetic Sensors - I Magnetic Oxides & Heusler Alloys - I Transport Theory and Semiconductors Spintronics Longitudinal and Particulate Media Magnetic Nanoclusters and Nanoparticles - I Soft Magnetic Materials & EMC GMR for Multilayers and Nanostructures Fundamental Properties for Applications Permanent Magnet Materials – Applications - I Intermetallics and Other Hard Magnets	Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room
---	--	--	--

Monday Oral Sessions 2:30 pm – 5:00 pm	BA BB BC BD BE BF BG BH	Symposium on the Importance of GMR Head-Media Interface and Tribology - I MEMS and Miniature Magnetic Sensors Magnetic Sensors - II Molecular and Novel Materials - I Magnetic Semiconductors - I Microwave Materials and Devices - I Multilayer Films and Superlattices - I	Auditorio A Madrid Roma Paris Londres Berlin Amsterdam Caracas
---	--	---	---

Monday GMR Nobel Celebration 5:10 pm	YA	GMR Nobel Celebration	Auditorio A
---	----	-----------------------	-------------

Tuesday Oral Sessions 9:30 am – 12:30 pm	CA CB CC CD CE CF CG CH	Symposium on Biomedical Applications Spin Torque Oscillators - I MgO Magnetic Tunnel Junctions - I Magnetic Microscopy - I Exchange Bias - I Electrical Steels and Inductor Cores Thin films: Surface and Anisotropy Properties Magnetic Shape Memory Alloys	Auditorio A Madrid Roma Paris Londres Berlin Amsterdam Caracas
---	--	---	---

Tuesday Poster Sessions 9:00 am – 1:00 pm	CL CM CN CO CP CQ CR CS CT CU CV CW	Permanent Magnet Machines - I Magnetic Micro and Nanostructures Micromagnetics – I Nanostructured Hard Magnetic Materials - I Hysteresis Modelling - I Soft Magnetic Materials and Applications - I Magnetic Nanoclusters and Nanoparticles - II Perpendicular Granular Media Perpendicular High Ku Media Bit Patterned Media - I Microwave Materials and Devices – II Characterization and Measurement Techniques - II	Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room
--	--	--	--

Tuesday Oral Sessions 2:30 pm – 5:30 pm	DA DB DC DD DE DF DG	Bit Patterned Media - II Symposium on Magnetic Modeling GMR in Nanocontacts and Constrictions Permanent Magnet Machines - II Soft Magnetic Wires Recording Systems and Servo - I Life Sciences: Techniques and Instrumentation - I	Auditorio A Madrid Roma Paris Londres Berlin Amsterdam
--	--	--	--

Tuesday Poster Sessions 2:30 pm – 6:30 pm	DL DM DN DO DP DQ DR DS DT DU DV DW	Ultrathin Films and Surface Effects - I Ultrathin Films and Surface Effects - II Magnetic Microscopy - II Magneto-Optic Materials and Devices Spin Torque Oscillators – II Life Science and Applications - I Magnetic Elements and Antidot Arrays Microwave Systems RE-TM Borides and Magnet Processing Permanent Magnet Materials - Applications - II Manganites Transformers and Inductors - II	Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room Polivalente Room
--	--	--	--

Tuesday Annual General Meeting 6:40 pm – 7:40 pm	XA	IEEE Magnetics Society Annual General Meeting (All Intermag attendees welcome)	Auditorio A
---	----	---	-------------

Wednesday

Oral Sessions

9:30 am – 12:30 pm	EA	Symposium on Spin Transfer and Dynamics	Auditorio A
	EB	Motor and Actuators - II	Madrid
	EC	Magnetic Nanostructures - I	Roma
	ED	Perpendicular Media	Paris
	EE	Magnetic Nanoparticles - I	Londres
	EF	Recording Physics, Models and Theory - I	Berlin
	EG	Soft Magnetic Materials and Applications - II	Amsterdam
	EH	Magneto-Dielectric Materials	Caracas

Wednesday

Poster Sessions

9:00 am – 1:00 pm	EL	Permanent Magnet Machines - III	Polivalente Room
	EM	Exchange Bias - II	Polivalente Room
	EN	Shielding, Levitation and Transport	Polivalente Room
	EO	Molecular and Novel Materials - I	Polivalente Room
	EP	Magnetodynamics and Millimetre Wave Devices	Polivalente Room
	EQ	Magnetic Semiconductors - II	Polivalente Room
	ER	Magnetic Semiconductors - III	Polivalente Room
	ES	Recording Heads	Polivalente Room
	ET	Magnetoelastic and Magnetoelectric Materials	Polivalente Room
	EU	Ferrite Dynamics and Applications	Polivalente Room
	EV	Magnetostriuctive Shape Memory Alloys/Devices	Polivalente Room
	EW	Multiferroics, Ferrites and Other Materials	Polivalente Room
	EX	Magnetic Tunnel Junctions - II	Polivalente Room

Wednesday

Oral Sessions

2:30 pm – 4:30 pm	FA	Symposium on Spin Torque Transfer for MRAM	Auditorio A
	FB	Spin Injection and Spin Hall Effect	Madrid
	FC	Magneto-Electronic Devices	Roma
	FD	Magnetic Oxides & Heusler Alloys - II	Paris
	FE	Life Science and Applications - II	Londres
	FF	Microwave Devices and FMR	Berlin
	FG	Nanostructured Hard Magnetic Materials - II	Amsterdam
	FH	Oxide Multiferroics and Ferrites	Caracas

Wednesday

Awards and Plenary Session

4:40 pm – 6:40 pm	WA	IEEE Magnetics Society Awards Ceremony Intermag Plenary Session	Auditorio A
-------------------	----	--	-------------

Plenary Reception

6:45 pm – 8:00 pm		Magnetics Society Plenary Reception	Polivalente Room
-------------------	--	-------------------------------------	------------------

Thursday

Oral Sessions

9:30 am – 12:30 pm	GA	Symposium on Bit Patterned Media	Auditorio A
	GB	MR Based Heads (GMR, MTJ, CPP)	Madrid
	GC	Ultrafast Dynamics	Roma
	GD	MRAM	Paris
	GE	Magnetic Nanoparticles - II	Londres
	GF	Head-Media Interface and Tribology - II	Berlin
	GG	Hysteresis Modelling - II	Amsterdam
	GH	Permanent Magnet Materials - Applications - III	Caracas

Thursday

Poster Sessions

9:00 am – 1:00 pm	GL	Multilayer Films and Superlattices - II	Polivalente Room
	GM	Permanent Magnet Machines - IV	Polivalente Room
	GN	Motors and Actuators - III	Polivalente Room
	GO	Life Sciences: Techniques and Instrumentation - II	Polivalente Room
	GP	Switched Reluctance Machines	Polivalente Room
	GR	Soft Nanocrystalline Alloys	Polivalente Room
	GS	Power and Control Magnetics	Polivalente Room
	GT	Spin Torque Excitations in Nanomagnets	Polivalente Room
	GU	Magnetocaloric Effect and Materials	Polivalente Room
	GV	Fast Switching of Films and Nanostructures	Polivalente Room
	GW	Computational Magnetics	Polivalente Room
	GX	Miscellaneous – I	Polivalente Room
	GY	Miscellaneous – II	Polivalente Room

Thursday

Oral Sessions

2:30 pm – 5:30 pm	HA	Symposium on the Roadmap for Spintronics	Auditorio A
	HB	Inductive Recording Heads and Materials	Madrid
	HC	Magnetization Dynamics	Roma
	HD	Micromagnetics – II	Paris
	HE	Permanent Magnet Materials	Londres
	HF	Life Science and Applications - III	Berlin
	HG	Magnetoelastic Materials and Devices	Amsterdam
	HH	Current Induced DW Motion	Caracas

Thursday

Poster Sessions

2:30 pm – 6:30 pm	HL	Recording Systems and Servo - II	Polivalente Room
	HM	Recording Systems, Coding and Channel - I	Polivalente Room
	HN	Magnetic Nanoclusters and Nanoparticles - III	Polivalente Room
	HO	Head-Media Interface and Tribology – III	Polivalente Room
	HP	Soft Films	Polivalente Room
	HQ	Domain Walls in Nanowires and Thin Films	Polivalente Room
	HR	MgO Magnetic Tunnel Junctions - II	Polivalente Room
	HS	Ab Initio Calculations	Polivalente Room
	HT	Recording Systems, Coding and Channel - II	Polivalente Room
	HU	Multilayer Films and Superlattices - III	Polivalente Room
	HV	Magneto-Optic, HAMR and Novel Recording	Polivalente Room
	HW	Recording Physics, Models and Theory - II	Polivalente Room

Thursday

Closing Reception

8:30 pm – 10:00 pm		Government of the Autonomous Community of Madrid (by invitation)	Real Casa de Correos, Plaza de la Puerta del Sol
--------------------	--	--	---

SUNDAY
AFTERNOON
5:00

AUDITORIO A

10:15

AA-03. Coherent control of spin transfer torque magnetization dynamics. S. Serrano-Guisan¹, K. Rott², G. Reiss², B. Ocker³, J. Langer³ and H.W. Schumacher¹. *1. Physikalisch-Technische Bundesanstalt, Braunschweig, Germany; 2. Department of Physics, University of Bielefeld, Bielefeld, Germany; 3. Singulus Nano Deposition Technologies GmbH, Kahl am Main, Germany*

10:30

AA-04. Real Time Measurements of Spin-Transfer Switching in CoFeB/MgO/CoFeB Magnetic Tunnel Junctions. H. Tomita¹, K. Konishi¹, T. Nozaki¹, M. Shiraishi¹, H. Kubota², A. Fukushima², S. Yuasa² and Y. Suzuki¹. *1. Osaka university, Toyonaka, Osaka, Japan; 2. National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan*

10:45

AA-05. Observation of intermediate states in large magnetic tunnel junctions with composite free layer. X. Yao¹, R. Malmhall², R. Ranjan² and J. Wang¹. *1. MINT Center & Electrical and Computer Engineering Department, Univ. Of Minnesota, Minneapolis,, MN; 2. Yadav Technology, Fremont, CA*

11:00

AA-06. Spin transfer switching in magnetic tunnel junctions with several compositions of the free layer. D. Watanabe¹, M. Oogane¹, Y. Ando¹ and T. Miyazaki². *1. Applied Physics, Tohoku University, Sendai, Japan; 2. WPI-AIMR, Tohoku University, Sendai, Japan*

11:15

AA-07. Spin Torque Induced Magnetization Switching Variations. X. Wang¹, W. Zhu¹, M. Siegert¹ and D. Dimitrov¹. *1. Seagate Technology, Bloomington, MN*

11:30

AA-08. Spin-torque driven ferromagnetic resonance of Co/Ni synthetic layers in spin valves. W. Chen¹, G. de Loubens¹, J.L. Beaujour¹, A.D. Kent¹ and J.Z. Sun². *1. Physics, New York University, New York, NY; 2. IBM T. J. Watson Research Center, IBM, Yorktown Heights, NY*

11:45

AA-09. Spin torque transfer in deep submicron annular cpp-gmr devices. M.T. Moneck¹, X. Zhu¹ and J. Zhu¹. *1. Electrical & Computer Engineering, Carnegie Mellon University, Pittsburgh, PA*

12:00

AA-10. Effective description of planar spin-transfer devices. Y. Bazaliy^{1,2}. *1. Department of Physics and Astronomy, University of South Carolina, Columbia, SC; 2. Institute of Magnetism, National Academy of Science, Kyiv, Ukraine*

12:15

AA-11. Magnetization reversal driven by spin-injection : a mesoscopic spin transfer effect. J. Wegrowe¹. *1. LSI, Ecole Polytechnique, Palaiseau, France*

MONDAY
MORNING
9:30

AUDITORIO A

Session AA
SPIN-TORQUE SWITCHING
Xian Jiang, Chair

9:30

AA-01. Magneto-optical and spin transfer switching properties of current-perpendicular-to plane spin valves with perpendicular magnetic anisotropy. (Invited) K. Aoshima¹, N. Funabashi¹, K. Machida¹, Y. Miyamoto¹, N. Kawamura¹, K. Kuga¹, N. Shimidzu¹, T. Kimura² and Y. Otani². *1. Science & Technical Research Laboratories, Japan Broadcasting Corp., Setagaya, Tokyo, Japan; 2. The Institute for Solid State Physics, The Tokyo University, Kashiwa, Chiba, Japan*

10:00

AA-02. Time-resolved magnetization switching induced by spin-transfer in Magnetic MgO tunnel junctions. T. Devolder¹, J. Hayakawa^{2,3}, K. Ito², H. Takahashi², S. Ikeda³, P. Crozat¹, J.V. Kim¹, C. Chappert¹ and H. Ohno³. *1. Institut d'Electronique Fondamentale, ORSAY Cedex, France; 2. Advanced Research Laboratory, Hitachi, Ltd, Tokyo, Japan; 3. Laboratory for Nanoelectronics and Spintronics, Research Institute of Electrical Communication, Tohoku University, Sendai, Japan*

MONDAY
MORNING
9:30

MADRID

11:00

AB-07. Propagation field of notched permalloy nanowires. *P. Warnicke*¹, A. Himeno², S. Kasai² and T. Ono² *1. Department of Engineering sciences, Division for solid state physics, Uppsala, Sweden; 2. Institute for Chemical Research, Division of materials research, Kyoto, Japan*

Session AB
DOMAIN WALLS IN NANOWIRES

Del Atkinson, Chair

11:15

AB-08. Measuring domain wall coherence lengths using a chirality filter. *E. Lewis*¹, D. Petit¹, A. Jausovec¹, L. O'Brien¹, H. Zeng¹, D. Read¹ and R. Cowburn¹ *1. Imperial College London, London, United Kingdom*

11:30

AB-09. Dynamic of depinning of a magnetic domain wall from a single defect. *F. Montaigne*¹, J. Briones¹, D. Lacour¹, M. Hehn¹, M.J. Carey² and J. Childress² *1. Laboratoire de Physique des Matériaux, Nancy-University, CNRS, Vandoeuvre lès Nancy, France; 2. Hitachi San Jose Research Center, San Jose, CA*

11:45

AB-10. Direct observation of the Walker breakdown during field driven domain wall (DW) motion in Permalloy nanowires. *R. Mattheis*¹ and S. Glathe¹ *1. Photonic Instrumentation, IPHT, Jena, Germany*

12:00

AB-11. Control of field driven domain wall (DW) motion by transversal fields: suppression of Walker breakdown and giant velocities. *S. Glathe*¹, R. Mattheis¹ and T. Mikolajick² *1. Photonic Instrumentation, IPHT, Jena, Germany; 2. Institute of Electronic and Sensor Materials, TU Bergakademie Freiberg, Freiberg, Germany*

12:15

AB-12. Domain-Wall Trapping by Localized Field on Submicron Permalloy Wire. *L. Ji*¹, A. Orlov¹, G.H. Bernstein¹ and W. Porod¹ *1. Electrical Engineering, University of Notre Dame, Notre Dame, IN*

9:30

AB-01. Current-Induced Magnetic Domain Wall Motion at Low Current Density via Perpendicular Anisotropy. *S. Jung*¹, W. Kim², T. Lee², K. Lee³ and H. Lee¹ *1. Physics, POSTECH, Pohang, South Korea; 2. Materials Science, KAIST, Daejeon, South Korea; 3. Materials Science and Engineering, Korea University, Seoul, South Korea*

9:45

AB-02. Current-induced Domain Wall Transformations and Vortex Core Displacement. *L. Heyne*¹, D. Backes^{1,2}, T.A. Moore¹, S. Krzyk¹, M. Kläui¹, U. Rüdiger¹, L.J. Heyderman², A. Fraile Rodriguez², F. Nolting², O. Mentès³, M. Nino³, A. Locatelli³, K. Kirsch⁴ and R. Mattheis⁴ *1. Universität Konstanz, Konstanz, Germany; 2. Paul Scherrer Institut, Villigen, Switzerland; 3. Sincrotrone Trieste, Trieste, Italy; 4. Institute of Photonic Technology, Jena, Germany*

10:00

AB-03. Dynamics of domain walls in soft magnetic nanostripes: soliton approach. *K. Guslienko*¹, J. Lee¹ and S. Kim¹ *1. Research Center for Spin Dynamics & Spin-Wave Devices and Nanospintronics Laboratory, Materials Science & Eng. Dept., Seoul National University, Seoul, South Korea*

10:15

AB-04. Pinning and propagation of vortex domain walls in triangular anti-notches. *K.J. O'Shea*¹, J.N. Chapman¹, S. McVitie¹ and Y.H. Wu² *1. Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom; 2. Electrical and Computer Engineering, National University Singapore, Singapore, Singapore*

10:30

AB-05. Domain wall pinning mechanism in ferromagnetic nanowires. *D. Petit*¹, A. Jausovec¹, E. Lewis¹, H.T. Zeng¹, L. O'Brien¹, D. Read¹ and R.P. Cowburn¹ *1. Physics, Imperial College London, London, United Kingdom*

10:45

AB-06. The dependence of wire width and trap geometry on domain wall pinning behaviour in nanowires. *L.K. Bogart*¹, D. Eastwood¹, D. Atkinson¹, D. McGrouther², K. O'Shea², S. McVitie² and J. Chapman² *1. Physics, Durham University, Durham, United Kingdom; 2. Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom*

MONDAY
MORNING
9:30

ROMA

Session AC
MAGNETIC TUNNEL JUNCTIONS - I
Wolfram Maass, Chair

9:30

AC-01. Tunnel magnetoresistance over 100 % in MgO based magnetic tunnel junction films with perpendicular magnetic L1₀-FePt electrodes. *M. Yoshikawa*¹, E. Kitagawa¹, T. Nagase¹, T. Daibou¹, M. Nagamine¹, K. Nishiyama¹, T. Kai¹, N. Shimomura¹, M. Amano¹, S. Takahashi¹, T. Kishi¹ and H. Yoda¹ *1. Corporate Research & Development Center, TOSHIBA Corporation, Kawasaki, Japan*

9:45

AC-02. Interfacial Oxidation Enhanced Perpendicular Magnetic Anisotropy in Low Resistance Magnetic Tunnel Junctions Composed of Co/Pt Multilayer Electrodes. *J. Park¹, C. Park² and J. Zhu¹. Carnegie Mellon University, Pittsburgh, PA; 2. Western Digital Corporation, Fremont, CA*

10:00

AC-03. Large Tunneling Anisotropic Magnetoresistance in a Magnetic Tunnel Junction with a Single Ferromagnet CoPt. *B. Park¹, J. Wunderlich¹, S. Joo², K. Jung², K. Shin², A. Shick³ and T. Jungwirth^{3,4}. 1. Hitachi Cambridge Laboratory, Cambridge, United Kingdom; 2. Nano Device Research Center, KIST, Seoul, South Korea; 3. Institute of Physics ASCR, Pargue, Czech Republic; 4. School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom*

10:15

AC-04. Crossover from Kondo assisted suppression to cotunneling enhancement of tunneling magnetoresistance via ferromagnetic nanodots in MgO tunnel barriers. *H. Yang^{1,2}, S. Yang¹ and S. Parkin¹. 1. IBM Almaden Research Center, San Jose, CA; 2. ECE, National University of Singapore, Singapore, Singapore*

10:30

AC-05. Magneto-Coulomb effects through isolated nanoparticles connected to ferromagnetic electrodes. *A. Bernand-Mantel¹, P. Seneor², B. Dlubak², V. Cros², S. Fusil², K. Bouzehouane², C. Deranlot², A. Vaures², R. Guillemet², F. Petroff² and A. Fert². 1. Kavli Institute of Nanoscience, Delft University of Technology, Delft, Netherlands; 2. Unite Mixte de Physique CNRS/Thales associated with University Paris-sud, Palaiseau, France*

10:45

AC-06. Fabrication and characterization of magnetic tunnel junctions using Co₂MnSi electrode and MgO tunneling barrier. *S. Tsunegi¹, Y. Sakuraba², M. Oogane¹, K. Takanashi² and Y. Ando¹. 1. Applied physics, Tohoku University, Sendai, Japan; 2. Institute for Materials Research, Tohoku University, Sendai, Japan*

11:00

AC-07. Spin-dependent tunneling conductance in fully epitaxial Co₂MnSi/MgO/Co₂MnSi tunnel junctions. *T. Ishikawa¹, N. Itabashi¹, K. Matsuda¹, T. Uemura¹ and M. Yamamoto¹. 1. Division of Electronics for Informatics, Hokkaido University, Sapporo, Japan*

11:15

AC-08. Spin-polarized tunneling characteristics of the room temperature spin filter CoFe₂O₄. *A.V. Ramos¹, R. Mattana², F. Petroff², T.S. Santos^{3,4}, G. Miao³ and J.S. Moodera³. 1. DSM/DRECAM/SPCSI, CEA Saclay, Gif-sur-Yvette, France; 2. Unite Mixte de Physique, CNRS/Thales, Palaiseau, France; 3. Francis Bitter Magnet Laboratory, MIT, Cambridge, MA; 4. Argonne National Laboratory, Argonne, IL*

11:30

AC-09. *In Situ* Lorentz Study of Disorder, Fluctuations, and Breakdown in Magnetic Tunnel Junctions. *S.E. Russek¹, J.M. Shaw¹ and R. Geiss¹. 1. National Institute of Standards and Technology, Boulder, CO*

11:45

AC-10. Pulse Width Dependence of Barrier Breakdown in MgO Magnetic Tunnel Junctions. *J. Hérault¹, R. Sousa¹, C. Papusoi¹, Y. Conraux², I. Prejbeanu², K. Mackay², J. Nozières² and B. Dieny¹. 1. Spintec (URA 2512 CEA/CNRS), Grenoble, France; 2. Crocus Technology, Grenoble, France*

12:00

AC-11. Spin dependent transport through an organic semiconductor tunnel barrier. *C. Barraud^{1,2}, P. Seneor^{1,2}, R. Mattana^{1,2}, R. Guillemet^{1,2}, S. Fusil^{1,2}, K. Bouzehouane^{1,2}, C. Deranlot^{1,2}, A. Vaures^{1,2}, F. Petroff^{1,2}, A. Fert^{1,2}, P. Graziosi³, L. Hueso³, I. Bergenti³ and V. Dediu³. 1. Unité Mixte de Physique CNRS/Thales, Palaiseau, France; 2. Department of Physics, University of Paris-Sud 11, Orsay, France; 3. Istituto per lo Studio dei Materiali Nanostrutturati, ISMN-CNR, Bologna, Italy*

12:15

AC-12. Theoretical studies on spin-dependent conductance in FePt/MgO/FePt(001) magnetic tunnel junctions. *Y. Taniguchi¹, Y. Miura¹, K. Abe¹ and M. Shirai¹. 1. Research Institute of Electrical Communication, Tohoku University, Sendai, Japan*

MONDAY
MORNING
9:30

PARIS

Session AD THIN FILMS: INTERFACE AND TRANSPORT PROPERTIES

Sergej Demokritov, Chair

9:30

AD-01. Fe-induced spin-polarized electronic states in a realistic semiconductor tunnel barrier. *M. Marangolo¹ and F. Finocchi¹. 1. INSP, Université Pierre et Marie Curie, Paris, France*

9:45

AD-02. Spin polarised electrodes and interfaces in organic spintronic devices. *I. Bergenti¹, A. Dediu¹, F. Borgatti¹, A. Riminucci¹, L.H. Hueso⁵, F. Casoli², Y. Zhan³, C. Pernechele⁴ and M. Solzi⁴. 1. ISMN CNR, Bologna, Italy; 2. CNR-IMEM, Parma, Italy; 3. Department of Physics, IFM, Linköping University, Linköping, Sweden; 4. Dipartimento di Fisica, Università di Parma, Parma, Italy; 5. Department of Physics and Astronomy, University of Leeds, Leeds, United Kingdom*

10:00

AD-03. Voltage control of the in-plane magnetic hysteresis in Fe/Au/Fe(001) and Fe (001) ultrathin films grown on GaAs (001) surface. K. Ohta¹, Y. Suzuki¹, T. Maruyama¹, T. Nozaki¹, T. Shinjo¹, M. Shiraishi¹, S. Ha², C. You² and W. Van Roy³ *1. Engineering Science, Osaka University, Toyonaka, Japan; 2. Department of Physics, Inha University, Incheon 402-751, South Korea; 3. IMEC, B-3001 Leuven, Belgium*

10:15

AD-04. Extraordinary increase of the resistivity and decrease of the Curie temperature in ultrathin LSMO films capped with Au. M. Cantoni¹, S. Brivio¹, D. Petti¹, A. Cattoni¹, R. Bertacco¹, A.A. Sidorenko², G. Allodi², M. Ghidini² and R. De Renzi² *1. Physics, Politecnico di Milano, Como, Italy; 2. Physics, Università di Parma, Parma, Italy*

10:30

AD-05. Influence of interfacial oxygen on spin filtering and antiferromagnetic coupling in single-crystalline Fe/MgO/Fe(001) magnetic tunnel junctions. F. Bonell¹, S. Andrieu¹, C. Tiusan¹, A.M. Bataille¹, B. Kierren¹, F. Montaigne¹ and G. Lengaigne¹ *1. Nanomagnetism and Spintronics Team, Laboratoire de Physique des Matériaux - Université Henry Poincaré - UMR 7556, Vandoeuvre-lès-Nancy, France*

10:45

AD-06. Interface magnetism in ultra-thin Mo/Co multilayers. L. Baczewski¹, K. Mergia², J. Kisielewski³, A. Maziewski³ and F. Ott⁴ *1. Institute of Physics Polish Academy of Sciences, Warsaw, Poland; 2. Institute of Nuclear Technology and Radiation Protection, Athens, Greece; 3. Institute of Experimental Physics, University of Białystok, Białystok, Poland; 4. Laboratoire Leon Brillouin, CEA, Saclay, France*

11:00

AD-07. Noncollinear Surface Spin Density of equiatomic NiMn alloy on Cu(001). C. Gao¹, A. Ernst¹, A. Winkelmann¹, J. Henk¹, W. Wulfhekel^{1,2}, P. Bruno¹ and J. Kirschner¹ *1. Max Planck Institute of Microstructure Physics, Halle (Saale), Germany; 2. Physikalisches Institut, Universität Karlsruhe (TH), Karlsruhe, Germany*

11:15

AD-08. Room temperature ferromagnetism in pristine and Mn-doped ZnO thin films. H. Nguyen¹, E. Chikoidze² and Y. Dumont² *1. Faculté des Sciences et Techniques, Université F. Rabelais, Laboratoire LEMA, UMR 6157 CNRS/CEA, Tours, France; 2. GeMAC, UMR 8635, CNRS-University of Versailles, Meudon, France*

11:30

AD-09. Tailoring the magnetic properties of all-ferromagnetic artificial FeCu(111) alloy thin films. M. Niño^{1,2}, J. Camarero¹, W. Kuch³, R. Abrudan^{3,4}, N. Mikuszeit^{1,5}, C. Tieg^{4,6}, M.P. Jigato¹, J. Kirschner⁴, J. de Miguel¹ and R. Miranda^{1,7} *1. Departamento de Física de la Materia Condensada, Instituto de Materiales “Nicolás Cabrera” and Universidad Autónoma de Madrid, Madrid, Spain; 2. ELETTRA-Sincrotrone Trieste, Basovizza, Italy; 3. Institut für Experimentalphysik, Freie Universität Berlin, Berlin, Germany; 4. Max-Planck Institut für Mikrostrukturphysik, Halle, Germany; 5. Institut für Angewandte Physik, Universität Hamburg, Hamburg, Germany; 6. European Synchrotron Radiation Facility-ESRF, Grenoble, France; 7. Instituto Madrileño de Estudios Avanzados en Nanociencia IMDEA-Nanociencia, Madrid, Spain*

11:45

AD-10. Magnetic properties of ultra thin magnetite film grown by molecular beam epitaxy. S.K. Arora¹, W. HanChun¹, I.V. Shvets¹, O.N. Mryasov², H. Yao³ and W.Y. Ching³ *1. Centre for Adaptive Nanostructures and Nanodevices (CRANN), School of Physics, Trinity College Dublin, Dublin, Dublin, Ireland; 2. Seagate Research Center, Seagate Technology, Pittsburgh, PA, 15222, PA; 3. Department of Physics, University of Missouri-Kansas City, Kansas City, MO, 64110, KS*

12:00

AD-11. Structure and magnetism of ultra-thin chromium layers on W(110). B. Santos^{1,2}, J.M. Puerta³, J.I. Cerda³, R. Stumpf⁴, K. von Bergmann⁵, R. Wiesendanger⁵, M. Bode^{5,6}, K.F. McCarty⁴ and J. de la Figuera^{1,2} *1. Instituto de Química-Física Rocasolano, CSIC, Madrid, Madrid, Spain; 2. Centro de Microanálisis de Materiales, Universidad Autónoma de Madrid, Madrid, Madrid, Spain; 3. Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Madrid, Spain; 4. Sandia National Laboratories, Livermore, CA; 5. Institute of Applied Physics and Microstructure Research Center, University of Hamburg, Hamburg, Germany; 6. Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL*

12:15

AD-12. Quantum-size induced oscillations of the electron-spin motion in Au films on Co(001). L. Tati Bismaths¹, L. Joly², F. Scheurer¹ and W. Weber¹ *1. Institut de Physique et Chimie des Matériaux de Strasbourg, Strasbourg, France; 2. Swiss Light Source, Villigen, Switzerland*

MONDAY
MORNING
9:30

LONDRES

Session AE

HEAT AND MICROWAVE ASSISTED RECORDING

Duane Karns, Chair

9:30

AE-01. Monolithically-fabricated hybrid head for near field assisted magnetic recording. (Invited) *S. Miyanishi¹, K. Innami¹, T. Naka¹, T. Kitazawa¹, M. Yagura¹, N. Teraguchi¹, Y. Murakami¹ and A. Takahashi¹* *1. Advanced Technology Research Laboratories, SHARP CORPORATION, Tenri, Nara, Japan*

10:00

AE-02. Exploiting far- and nar-fiel optics to develop energy efficient transducer for heat-assisted magnetic recording. *R. Ikkawi¹, N. Amos¹, A. Krichevsky¹, A. Lavrenov¹, D. Litvinov² and S. Khizroev¹* *1. Electrical Engineering, University of California, Riverside, Riverside, CA; 2. Center for Nanomagnetic Systems, University of Houston, Houston, TX*

10:15

AE-03. Design and characterization of a media thermal stack for confining lateral thermal heat flow. *D. Karns¹, G. Ju¹, A. Itagi¹ and B. Lu¹* *1. Seagate Technologies, Pittsburgh, PA*

10:30

AE-04. Domain structure in TbFeCo/FePt-grains composite film and Cu doping effect on Curie temperature of FePt grains. *A. Itoh¹, A. Tsukamoto¹, F. Chino², S. Iwase², Y. Sano² and K. Okayama²* *1. Dep. of Electronics and Computer Science, College of Science and Technology, Nihon University, Funabashi, Chiba, Japan; 2. Dep. of Electronics, Graduate School of Nihon University, Funabashi, Chiba, Japan*

10:45

AE-05. Magnetic properties of amorphous magnetic film on self-assembled convex pattern. *N. Iwata¹, D. Honda¹, Y. Murakami¹ and A. Takahashi¹* *1. Advanced Technology Research Laboratories, SHARP CORPORATION, Tenri, NARA, Japan*

11:00

AE-06. Comparison of Dual and Thermal Gradient Recording Methods for Thermally Assisted Magnetic Recording. *F. Akagi¹, T. Matsumoto¹ and M. Igarashi¹* *1. Hitachi, Ltd., Tokyo, Japan*

11:15

AE-07. Investigation of magnetic reversal modes for Heat Assisted Magnetic Recording. *R.F. Evans¹, P. Asselin², D. Hinzke¹, U. Nowak¹ and R.W. Chantrell¹* *1. Physics, University Of York, York, England, United Kingdom; 2. Seagate Research, Pittsburgh, PA*

11:30

AE-08. Modeling of thermally-activated switching of single phase, exchange-coupled and graded media. *O. Chubykalo-Fesenko¹, U. Atxitia¹ and D. Suess²* *1. POMT, Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain; 2. Vienna University of Technology, Vienna, Austria*

11:45

AE-09. Application of plasmon resonances to all-optical magnetic recording. *I. Mayergoyz¹, Z. Zhang¹, P. McAvoy¹ and C. Krafft²* *1. ECE Department and UMLACS, University of Maryland, College Park, MD; 2. Laboratory for Physical Sciences, College Park, MD*

12:00

AE-10. Narrow Track Confinement by AC Field Generation Layer in Microwave Assisted Magnetic Recording. *Y. Tang¹ and J. Zhu¹* *1. Electrical and Computer Engineering, Carnegie Mellon University, Pittsburgh, PA*

12:15

AE-11. LLG Simulation of Microwave Assisted Switching in Isolate Particle. *M. Igarashi¹, Y. Suzuki¹, H. Miyamoto¹, Y. Maruyama², H. Fukui² and Y. Shiroishi²* *1. Hitachi, Ltd., Kokubunji, Tokyo, Japan; 2. Hitachi Global Storage Technology, Odawara, Kanagawa, Japan*

MONDAY
MORNING
9:30

BERLIN

Session AF

CHARACTERIZATION AND MEASUREMENT TECHNIQUES I

Ernie Hill, Chair

9:30

AF-01. Hyperfine field distribution in the Heusler compound Co₂FeAl probed by ⁵⁹Co NMR. *S. Wurmehl¹, J.T. Kohlhepp¹, H. Swagten¹, B. Koopmans¹, C. Blum², B. Balke², G.H. Fecher² and C. Felser²* *1. Applied Physics, Eindhoven University of Technology, Eindhoven, Netherlands; 2. Institut für Anorganische und Analytische Chemie, Johannes Gutenberg-University, Mainz, Germany*

9:45

AF-02. Shedding light on magnetoelastic coupling and magnetostriction at an atomic level. *S. Pasquarelli¹, M. Ruffoni¹, A. Trapananti¹, O. Mathon¹, Y. Joly², R. Pettifer³, M. Pasquale⁴, A. Magni⁴, C.P. Sasso⁴, F. Celegato⁴ and E. Olivetti⁴* *1. European Synchrotron Radiation Facility, Grenoble, France; 2. Institut NEEL, CNRS/UJF, Grenoble, France; 3. Dept. of Physics, Univ. of Warwick, Coventry, United Kingdom; 4. INRIM, IENGf, Torino, Italy*

10:00

AF-03. Detection of magnetic reversal at a DW pinning site in Ni80Fe20 nanowires using concurrent Magneto-Optical Kerr Effect (MOKE) and electrical measurements. *H.T. Zeng¹, D. Read¹, D. Petit¹, L. O'Brien¹, E. Lewis¹, A. Jausovec¹ and R. Cowburn¹* *1. Physics, Imperial College London, London, United Kingdom*

10:15

AF-04. Material selective sensitivity of magneto-optical Kerr effect in NiFe/Au/Co/Au periodic multilayers. K. Postava^{1,2}, M. Tekielak¹, P. Mazalski¹, A. Maziewski¹, A. Stupakiewicz¹, M. Urbaniak³, B. Szymanski³ and F. Stobiecki³ *1. Laboratory of Magnetism, University of Bialystok, Bialystok, Poland; 2. Department of Physics, Technical University of Ostrava, Ostrava - Poruba, Czech Republic; 3. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland*

10:30

AF-05. Magnetic images of a surface crack on a heated specimen with the use of an area type magnetic camera with high spatial resolution. J. Lee¹ and J. Hwang² *1. Department of Information and Communication Engineering, Chosun University, Gwangju, South Korea; 2. Department of Information and Communication Engineering, Graduate School of Chosun University, Gwangju, South Korea*

10:45

AF-06. Magnetostriction of Iron at Low Temperatures Observed with X-Ray Diffraction. E. Arakawa¹ and N. Aizawa¹ *1. Physics Dept., Tokyo Gakugei University, Koganei,, Tokyo, Japan*

11:00

AF-07. Enhancement of magneto-optical Kerr signal from the nano-structure by employing anti-reflection coated substrate. C. You¹ and D. Kim¹ *1. Department of Physics, Inha University, Incheon, South Korea*

11:15

AF-08. Selective Magnetometry using a single x-ray absorption edge. J. Chaboy¹, M. Laguna-Marco¹, C. Piquer¹, R. Boada¹, H. Maruyama² and N. Kawamura³ *1. ICMA, Zaragoza, Zaragoza, Spain; 2. Graduate School of Science, Hiroshima University, Higashi-Hiroshima, Japan; 3. SPring-8/JASRI, Sayo, Hyogo, Japan*

11:30

AF-09. Open-circuit one-port network analyzer ferromagnetic resonance. C. Bilzer¹, T. Devolder¹, P. Crozat¹ and C. Chappert¹ *1. Institut d'Electronique Fondamentale, ORSAY Cedex, France*

11:45

AF-10. Discrimination of metallic coins using the scan type magnetic camera. J. Lee¹ and J. Jun² *1. Department of Information and Communication Engineering, Chosun University, Gwangju, South Korea; 2. Department of Information and Communication Engineering, Graduate School of Chosun University, Gwangju, South Korea*

12:00

AF-11. Apparent Image Effect in Closed-Circuit Magnetic Measurements. A.K. Higgins¹, C.H. Chen¹, C.D. Graham² and R.M. Strnat³ *1. University of Dayton Magnetics Lab, Dayton, OH; 2. University of Pennsylvania, Philadelphia, PA; 3. Magnetic Instrumentation, Inc, Indianapolis, IN*

12:15

AF-12. A GMR Based System for Pulsed Eddy Current NDE of Aircraft Structures. G. Yang¹, L. Udpal¹ and S. Udpal¹ *1. msu, East Lansing, MI*

MONDAY
MORNING
9:30

AMSTERDAM

Session AG TRANSFORMERS AND INDUCTORS I

Saibal Roy, Chair

9:30

AG-01. Fabrication and analysis of high-performance integrated solenoid inductor with magnetic core. (Invited) D. Lee¹, K. Hwang² and S.X. Wang¹ *1. Materials Science and Engineering, Stanford University, Stanford, CA; 2. Intel Corporation, Folsom, CA*

10:00

AG-02. Thin Film Integrated Power Inductor on Si and Its Performance in a 8MHz Buck Converter. N. Wang¹, T. O'Donnell¹, R. Meere¹, F. Rhen¹, S. Roy¹ and C. O'Mathuna¹ *1. Microsystems Centre, Tyndall National Institute, Cork, Ireland*

10:15

AG-03. CoNiFe applied in Microinductors for integrated dc-dc converters. T. El mastouli¹, J. Laur¹, J. Sanchez¹, M. Brunet¹, D. Bourrier¹ and M. Dilhan¹ *1. ISGE, Laboratory for Analysis and Architectures of Systems (LAAS - CNRS), Toulouse Cedex 4, France*

10:30

AG-04. High Q and High Current NiZnCu ferrite inductor for On-chip power module. S. Bae^{1,2}, Y. Hong^{1,2}, J. Lee^{1,2}, G.S. Abo^{1,2}, J. Jalli^{1,2}, A. Lyle^{1,2}, H. Han^{1,2} and G.W. Donohoe³ *1. Department of Electrical and Computer Engineering, University of Alabama, Tuscaloosa, AL; 2. MINT Center, University of Alabama, Tuscaloosa, AL; 3. Department of Electrical and Computer Engineering, University of Idaho, Moscow, ID*

10:45

AG-05. Synthesis of Bi-Zn-Al-B-Si-O nano-glass by sol-gel method for multilayer chip inductors. S. An¹ and S. Wi¹ *1. EMC R&D Group, Samsung Electro-Mechanics, Gyeonggi-Do, South Korea*

11:00

AG-06. Electrically Tunable Thin Film Magnetic Core using Synthetic Antiferromagnet Structure. N. An¹, A. Jander¹ and P. Dhagat¹ *1. Electrical Engineering&Computer Science, Oregon State University, Corvallis, OR*

11:15

AG-07. The effect of magnetic coating layer thickness on the performance of tunable magnetic inductors. N. Ning¹, X. Li¹, H. Seet¹, W. Ng¹ and Y. Xu² *1. Mechanical Engineering, National University of Singapore, Singapore, Singapore; 2. Electrical and Computer Engineering, National University of Singapore, Singapore, Singapore*

11:30

AG-08. Audible noise from amorphous metal and silicon steel based transformer core. *D. Azuma¹ and R. Hasegawa¹1. Metglas, Inc., Conway, SC*

11:45

AG-09. Development of a Novel Three-Phase Laminated Core Variable Inductor. *K. Nakamura¹, S. Hisada¹, K. Arimatsu², T. Ohinata², K. Sakamoto² and O. Ichinokura¹1. Graduate School of Engineering, Tohoku University, Sendai, Japan; 2. Tohoku Electric Power Co., Inc., Sendai, Japan*

12:00

AG-10. Magneto-mechanical resonance in a 3-phase transformer core under PWM voltage excitation. *X. Yao¹, P.P. Than², A.J. Moses¹ and F. Anayi¹1. School of Engineering, Cardiff University, Wolfson Centre for Magnetism, Cardiff, Wales, United Kingdom; 2. Drilling & Measurements, Schlumberger, Aberdeen, Scotland, United Kingdom*

12:15

AG-11. Modeling the mutual impedances of non-coaxial inductors for induction heating applications. *C. Carretero^{1,3}, J. Acero¹, R. Alonso², J. Burdío¹ and F. Monterde³1. Dept. of Electronics Engineering and Communications, University of Zaragoza, Zaragoza, Spain; 2. Dept. of Applied Physics, University of Zaragoza, Zaragoza, Spain; 3. Bosch-Siemens Home Appliances Group, Montañana (Zaragoza), Spain*

MONDAY
MORNING
9:30

CARACAS

Session AH MAGNETOIMPEDANCE

Larissa Panina, Chair

9:30

AH-01. High-frequency transverse incremental permeability and magnetoimpedance effect in CoFeHfO magnetic oxide nanofilms. *A. Le¹, M. Phan², V. Manuel³, H. Lee⁴, Q. Nguyen¹ and S. Yu¹1. BK 21 Physics Program and Department of Physics, Chungbuk National University, Cheongju 361-763, South Korea; 2. Advanced Composites Centre for Innovation and Science, University of Bristol, Queen's Building, Bristol, United Kingdom; 3. De Instituto de Ciencia de Materiales de Madrid, CSIC, Campus de Cantoblanco, 28049 Madrid, Spain; 4. Department of Physics Education, Kongju National University, Kongju 314-701, South Korea*

9:45

AH-02. Width dependence of magneto-impedance in sandwiched films. *D. de Cos¹, A. Garcia-Arribas¹ and J. Barandiaran¹1. Electricidad y Electronica, Universidad del Pais Vasco, Bilbao, Spain*

10:00

AH-03. Annealing effects on the microwave absorption properties of nanocrystalline Fe₇₉Si₁₆B₅ microwires. *M. Han¹, L. Deng¹ and D. Liang¹1. State Key Laboratory of Electronic Thin Films and Integrated Devices, University of Electronic Science and Technology of China, Chengdu, Sichuan, China*

10:15

AH-04. Microwave absorption of amorphous microwires carrying a low frequency ac current. *A.G. Gorriti¹, I. Carabias¹, P. Marin¹ and A. Hernando¹1. Instituto de Magnetismo Aplicado, Las Rozas, Madrid, Spain*

10:30

AH-05. Magneto Impedance Behavior in Co/Cu/Co/NiFe Pseudo Spin Valve with a nano-oxide layer after Annealing Treatment. *W. Chien^{1,4}, R. Hung², C. Lo^{2,4}, Y. Yao^{1,3}, K. Chang⁴, E. Lai⁴, Y. Chen⁴, K. Hsieh⁴, C. Lu⁴ and P. Lin^{1,4}1. Department of Materials Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan; 2. Electronics and Optoelectronics Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan; 3. Department of Materials Engineering, Tatung University, Taipei, Taiwan; 4. Emerging Central Lab, Macronix International Co. Ltd, Hsinchu, Taiwan*

10:45

AH-06. Analysis of the intrinsic field sensitivity and noise of magnetoimpedance sensors. *L. Melo¹, D. Menard², A. Yelon², B. Dufay³, O. Mareschal³, S. Saez³ and C. Dolabdjian³1. Electrical Engineering, Ecole Polytechnique de Montreal, Montreal, QC, Canada; 2. Engineering Physics, Ecole Polytechnique de Montreal, Montreal, QC, Canada; 3. GREYC, ENSICAEN and University of Caen, Caen, France*

11:00

AH-07. Magneto impedance study in magneto tunneling junctions with different thickness of its barrier layer. *W. Chien¹, Y. Yao², J. Wu², C. Lo³, P. Lin¹ and X. Han⁴1. The Department of Materials Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan; 2. Department of Materials Engineering, Tatung University, Taipei, Taiwan; 3. Electronics and Optoelectronics Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan; 4. Institute of Physics, Chinese Academy of Sciences, Beijing, China*

11:15

AH-08. Development of thin microwires with enhanced magnetic softness and GMI. *V. Zhukova², M. Ipatov¹, J. Gonzalez¹, J. Blanco² and A. Zhukov^{1,3}1. Dept. of Phys. Materials, Basque Country University, San Sebastian, Spain; 2. Dpto. de Física Aplicada, EUPDS, Basque Country University, San Sebastian, Spain; 3. TAMAG Ibérica S.L., Parque Tecnológico de Miramón, Paseo Mikeletegi 56, 1 Planta, San Sebastian, Spain*

11:30

AH-09. Dependence of magneto-impedance on magnetic states in manganeses. *J. Li¹, H. Chou¹ and C. Lin¹1. Department of Physics and Center of Nanoscience, National Sun Yat-sen University, Kaohsiung, Taiwan*

11:45

AH-10. Temperature Dependence of Magnetoimpedance and Anisotropy in Nanocrystalline Finemet Wire. B. Hernando¹, J. Olivera¹, M. Sánchez¹, V.M. Prida¹ and R. Varga². *1. Fisica, Universidad de Oviedo, Oviedo, Asturias, Spain; 2. Inst. Physics, Fac.Sci.,UPJS, Park Angelinum, Kosice, Slovakia*

12:00

AH-11. Asymmetrical magnetoimpedance in CoFeSiB/CoNi layered microwires. J. Torrejon¹, G. Badini¹ and L.V. Panina². *1. Magnetism, ICMM (CSIC), Madrid, Spain; 2. School of Computing, Communication and Electronics, University of Plymouth, Plymouth, United Kingdom*

12:15

AH-12. Role of the interdomain wall in the giant magneto-impedance effect of thin microwires. H. Chiriac¹, T. Óvári¹ and S. Corodeanu¹. *1. National Institute of Research and Development for Technical Physics, Iasi, Romania*

MONDAY
MORNING
9:00

POLIVALENTE

Session AL MOTORS AND ACTUATORS I (POSTER SESSION) Elena Lomonova, Chair

AL-01. Development of an Axial-flux Spindle Motor for the Slim Optical Disc Drive. G. Yan¹, G. Huang¹, H. Wang¹ and L. Hsu². *1. Micro/Meso Mechanical Manufacturing Section, Metal Industries Research & Development Center, Kaohsiung, Taiwan; 2. Electric Motor Technology Research Center, National Cheng Cheng University, Tainan, Taiwan*

AL-02. Developments of a direct driven linear tubular generator for wave energy extraction. C. Liu¹, S. Yan¹, C. Lin¹, H. Lin¹, M. Lai¹ and C. Hwang². *1. Electrical Engineering, National Sun Yat-Sen University, Kaohsiung, Taiwan; 2. Electrical Engineering, Feng Chia University, Taichung, Taiwan*

AL-03. Mechanical resonance in non-oriented electrical steels induced by magnetostriction under pwm excitations. S. Somkun¹, A. Moses¹ and P. Anderson¹. *1. Wolfson Centre for Magnetism, Cardiff University, Cardiff, United Kingdom*

AL-04. Analysis of concentric magnetic gears using three dimensional scalar magnetic potential finite element method. L. Xinhua^{1,2}, C. K.t¹, J. J.z² and J. Linni¹. *1. Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, China; 2. School of Automation, Shanghai University, Shanghai, China*

AL-05. Reduction of the Torque Ripple and Unbalanced Magnetic Force of a Rotatory Two-Phase Transverse Flux Machine by Using Herringbone Teeth. G. Jang¹, H. Ahn¹, J. Chang², S. Chung² and D. Kang². *1. Dept. of Mechanical Engineering, PREM Lab., Hanyang University, Seoul, South Korea; 2. Korea Electrotechnology Research Institute, Changwon, South Korea*

AL-06. EVALUATION OF INDUCTION HEATING APPLICATION OF LINEAR INDUCTION MOTOR BY USING FEM CALCULATION. T. Yamada¹ and K. Fujisaki^{2,3}. *1. Nittetsu Plant Designing Corporation, Futtsu, Japan; 2. Nippon Steel Corporation, Futtsu, Japan; 3. Graduated School of Environmental Studies, Tohoku University, Sendai, Japan*

AL-07. Calculation of Stator End-winding Reactance of an Induction Machine Based on Magnetic Energy by 3-D Finite Element Analysis. R. Lin¹ and A. Arkkio¹. *1. Helsinki University of Technology, Espoo, Finland*

AL-08. Investigation of carrier loss of induction motors considering skin effect in electrical steel sheets. K. Yamazaki¹ and N. Fukushima¹. *1. Dept. of Electrical, Electronics and Computer Engineering, Chiba Institute of Technology, Narashino, Chiba, Japan*

AL-09. Characteristics Analysis of 3DOF Spherical Motor for robotic wrist motor. S. Won¹ and J. Lee¹. *1. Electrical Eng., Hanyang University, Seoul, South Korea*

AL-10. Electro-Magnetically Excited Vibration Testing for a Vibro-Acoustic Investigation on PMSMs in Hard Disk Drives. S. Suwankawin¹ and T. Jintanawan². *1. Electrical Engineering, Chulalongkorn University, Bangkok, Thailand; 2. Mechanical Engineering, Chulalongkorn University, Bangkok, Thailand*

AL-11. A Study on the Multi-Objective Optimal Design of Interior Permanent Magnet Synchronous Motor. K. Kim¹ and J. Lee¹. *1. Dept. of electrical engineering, hanyang university, seoul, South Korea*

AL-12. Analysis on Operating Characteristics of Auto Focusing VCM Actuator. Y. Choi¹, Y. Kim¹, G. Cho¹, Z. Piao¹, B. Min¹, H. Baek¹ and B. Chae². *1. Department of Electrical Engineering, Chosun University, Gwangju, South Korea; 2. Department of Electrical and Control Engineering, Korea Polytechic V College, Gwangju, South Korea*

AL-13. Development of Laser Beam Steering System Using Three Magnetostrictive Actuators. J. Jung¹, Y. Park¹ and K. Im¹. *1. Mechatronics Engineering, Chungnam National University, Daejeon, South Korea*

MONDAY
MORNING
9:00

POLIVALENTE

Session AM MAGNETIC SENSORS I (POSTER SESSION) Giovanni Badini-Confalonieri, Chair

AM-01. Magnetization process and induced pulse voltage of FeCoV wire implemented in tiny sensor chip. H. Tanaka¹, T. Kusunoki¹, T. Yamada¹, Y. Takemura¹, S. Abe², S. Kohno³ and H. Kondo³. *1. Department of Electrical & Computer Engineering, Yokohama National University, Yokohama, Japan; 2. Kanagawa University, Yokohama, Japan; 3. Nikkoshi Co., Ltd., Tokyo, Japan*

AM-02. The effect of ultrasonic resonance on impedance in magnetic rods. *H. Osada*¹, S. Nakamura¹, H. Hatafuku¹, S. Chiba¹ and H. Oka¹. *I. Iwate University, Morioka, Japan*

AM-03. Electrical Isolators based on Tunneling Magnetoresistance Technology. *C. Reig*¹, M.D. Cubells-Beltrán¹, D. Ramírez¹, S. Cardoso² and P.P. Freitas². *1. Electronic Engineering, Universitat de València, Burjassot, Spain; 2. Microsistemas e Nanotecnologias, INESC, Lisboa, Portugal*

AM-04. Introduction of a Base-Model for Eddy Current Testing of Printed Circuit Boards. *H. Bayani*¹, M. Nishino¹, *S. Yamada*¹ and M. Iwahara¹. *1. Division of Biological Measurement and Applications, Kanazawa University, Kanazawa, Japan*

AM-05. Orthogonal Fluxgate with Tube Core Operated in Fundamental Mode. *E. Paperno*¹, E. Wiess¹ and A. Plotkin¹. *1. Electrical and Computer Engineering, Ben-Gurion University of the Negev, Beer-Sheva, Israel*

AM-06. Test of multturn sensors by a system generating rotating electromagnetic fields with high rotational frequencies. *H. Koebe*¹, D. Schmidt¹, M. Scherzinger², K. Bauer² and R.M. Mattheis¹. *1. Photonic Instrumentation, IPHT, Jena, Germany; 2. Novotechnik, Ostfildern, Germany*

AM-07. External and internal bias field effect on giant magneto impedance profile. *H. Kim*¹, S. Park¹, D. Kim¹ and W. Jeung¹. *1. Division of Materials Science & Engineering, Korea Institute of Science and Technology, Seoul, South Korea*

AM-08. Magnetic Gradiometer for Magnetic Moment Measurement using Two Cesium Magnetometer in Earth's Magnetic Field Background. *P. Park*¹, Y. Kim¹, W. Kim¹ and V.Y. Shifrin². *1. Electromagnetic Metrology Group, Korea Research Institute of Standards and Science(KRISS), Daejeon, South Korea; 2. D. I. Mendeleyev Institute for Metrology (VNIIM), St. Petersburg, Russian Federation*

AM-09. Surface flaws detection using AC magnetic field sensing by a thin film inductive micro sensor. *K. Kim*¹, Y. Cha¹, J. Kim², J. Sohn² and Y. Yoo². *1. Physics, Yeungnam University, Gyeongsan, South Korea; 2. Institute of Nova Magnetics, Nova Magnetics, Incheon, South Korea*

AM-10. Linear magnetoresistance of NiO-spin valve device. *S. Lee*¹, Y. Park², D. Hwang³ and J. Rhee⁴. *1. Oriental Biomedical Engineering, Sangji University, Wonju, Gangwondo, South Korea; 2. Oriental Western Biomedical Engineering, Sangji University, Wonju, Gangwondo, South Korea; 3. Applied Physics and Electronics, Sangji University, Wonju, Gangwondo, South Korea; 4. Physics, Sookmyung Women's University, Seoul, Seoul, South Korea*

AM-11. Temperature Characteristics of Magnetic Rotation Angle Sensors With Spin-Valve GMR Films. *Y. Abe*², T. Ono² and T. Kawai¹. *1. New Business Development Center, Hitachi Metals, Tokyo, Japan; 2. OE Device Center, Hitachi Metals, Mooka, Japan*

AM-12. A simple design of an orthogonal fluxgate magnetometer of fundamental mode. *I. Sasada*¹ and H. Kashima¹. *1. Applied Science for Electronics and Materials, Kyushu University, Kasuga, Japan*

AM-13. Nitride based (AlGaIn/GaN) micro-Hall sensor. *A. Bengoechea*¹, *C. Aroca*¹, M.A. Sanchez-Garcia¹, E. Lopez² and P. Sanchez². *1. ISOM, Universidad Politécnica de Madrid, Madrid, Madrid, Spain; 2. Física de Materiales, Universidad Complutense de Madrid, Madrid, Madrid, Spain*

AM-14. Enhancement of sensitivity in a magnetic sensor by combining planar Hall resistance and giant Magnetoresistance. *H. Tran Quang*¹, S. Oh¹, D. Nguyen Huu² and C. Kim¹. *1. Department of Materials Science and Engineering, Chungnam National University, Daejeon, South Korea; 2. College of Technology, Vietnam National University, Hanoi, Viet Nam*

AM-15. Detection of magnetic particles for biological applications using a local-Hall device. *S. Joo*^{1,2}, Y. Kim¹, W. Lee¹, J. Lee¹, J. Hong^{1,2}, K. Rhie^{1,2} and K. Shin². *1. Applied Physics, Korea university, Seoul, South Korea; 2. Center for Spintronics Research, KIST, Seoul, South Korea*

AM-16. Fabrication and Characterization of Silicon Micro Hall Sensors for Scanning Hall Probe Microscopy (SHPM) Using Multiple Feedback Techniques. *R. Akram*¹, M. Dede¹ and A. Oral¹. *1. Department of Physics, Bilkent University, 06800, Ankara, Turkey*

AM-17. Magneto-impedance property in a micromachined magnetic LC-sensor device. *A. Le*¹, S. Yu¹, H. Lee² and V. Manuel³. *1. BK 21 Physics Program and Department of Physics, Chungbuk National University, Cheongju 361-763, South Korea; 2. Department of Physics Education, Kongju National University, Kongju 314-701, South Korea; 3. De Instituto de Ciencia de Materiales de Madrid, CSIC, Campus de Cantoblanco, 28049 Madrid, Spain*

**MONDAY
MORNING
9:00**

POLIVALENTE

**Session AN
MAGNETIC OXIDES & HEUSLER ALLOYS I
(POSTER SESSION)
Atsufumi Hirohata, Chair**

AN-01. Half-metallic magnetic materials and hybrid spintronic Structures. *(Invited) Y. Xu*¹. *1. Department of Electronics, The University of York, York, United Kingdom*

AN-02. Searching for quaternary Heusler alloys with half-metallicity. *X. Dai*¹, G. Liu¹, G. Fecher¹ and C. Felser¹. *1. Institut für Anorganische und Analytische Chemie, Johannes Gutenberg-Universität Mainz, Mainz, Germany*

AN-03. Universal scaling of the anomalous Hall effect in Fe3O4. *A. Fernández-Pacheco*^{1,2}, J.M. De Teresa², J. Orna^{1,2}, L. Morellón^{1,2}, P.A. Algarabel², J.A. Pardo^{1,3} and M.R. Ibarra^{1,2}. *1. Instituto de Nanociencia de Aragón, Zaragoza, Spain; 2. Instituto de Ciencias de los Materiales de Aragón, Zaragoza, Spain; 3. Departamento de Ciencia y Tecnología de Materiales y Fluidos, Universidad de Zaragoza, Zaragoza, Spain*

AN-04. Optimization of the Postgrowth Oxidation Preparation Process of Fe3O4/GaAs(100) Hybrid Structure. *S. Hassan*¹, Y. Xu¹, K. Wilson³, S. Thompson² and G. Van der Laan⁴. *1. Electronics, University of York, York, United Kingdom; 2. Physics, University of York, York, United Kingdom; 3. Chemistry, University of York, York, United Kingdom; 4. Daresbury Laboratory, Warrington, United Kingdom*

AN-05. Magnetic and transport properties of polycrystalline CaRu_{1-x}MoxO₃. Y. Ying¹, Y. Lee¹, K. Kim², H. Pan³ and Y. Zhang³ *1. Quantum Photonic Science Research Center and BK21 Program Division of Advanced Research and Education in Physics, Hanyang University, Seoul, South Korea; 2. Sunmoon University, Asan, South Korea; 3. National High Magnetic Field Laboratory, University of Science and Technology of China, Hefei, China*

AN-06. Atomic and electronic structure in ferromagnetic/superconducting oxide interfaces. M. Varela¹, J. Garcia-Barriocanal², A.R. Lupini¹, W. Luo^{3,1}, Z. Sefrioui², S.T. Pantelides^{3,1}, C. Leon², J. Santamaria² and S.J. Pennycook^{1,3} *1. Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN; 2. Departamento de Física Aplicada III, Universidad Complutense de Madrid, Madrid, Spain; 3. Department of Physics and Astronomy, Vanderbilt University, Nashville, TN*

AN-07. Magnetic phase coupled to an electric memory state in *d*⁰ oxide ZrO₂ films. Y. Jo¹, M. Jung¹, I. Hwang², B. Park² and S. Lee³ *1. Korea Basic Science Institute, DAEJEON, South Korea; 2. Konkuk University, SEOUL, South Korea; 3. Pohang University of Science and Technology, POHANG, South Korea*

AN-08. Perovskite-oxide pseudo spin valve structure. Y. Chan¹, W. Cheng¹, H. Lau¹ and C. Leung¹ *1. Department of Applied Physics, The Hong Kong Polytechnic University, Hong Kong, China*

AN-09. Grain-size effects on magnetic properties of sputtered Co₂MnSi films. S. Ladak² and A. Hirohata¹ *1. Department of Electronics, University of York, York, United Kingdom; 2. Department of Physics, University of York, York, United Kingdom*

AN-10. Effect of Nd doping on the spin polarization of Co₂MnSi Heusler alloy. A. Rajanikanth^{1,2}, Y.K. Takahashi² and K. Hono^{2,1} *1. International Center for Young Scientists, NIMS, Tsukuba, Ibaraki, Japan; 2. Magnetic Materials Center, NIMS, Tsukuba, Ibaraki, Japan*

AN-11. Anisotropy and magnetic dynamic properties of Co₂MnGe Heusler compound. M. Belmeguenai^{2,1}, F. Zighem¹, G. Woltersdorf², Y. Roussigné¹, S. Chérif¹, K. Westerholt³ and G. Bayreuther² *1. LPMTM Université Paris13, Villetaneuse, France; 2. Institut für Experimentelle Physik, Universität Regensburg, Regensburg, Germany; 3. Ruhr-Universität Bochum, Bochum, Germany*

AN-12. The effects of annealing temperature on structural and chemical properties of the Co₂Cr_{0.6}Fe_{0.4}Al surface and its relevance for the electron spin polarization at the surface. J. Wüstenberg¹, J. Fischer¹, A. Conca², M. Jourdan², M. Aeschlimann¹ and M. Cinchetti¹ *1. Institute of Physics, University of Kaiserslautern, Kaiserslautern, Germany; 2. Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany*

AN-13. The Different Capping Layer Influence on the Magnetic, Electronic and Structural Properties of the Co₂MnGa/GaAs(100) Hybrid Structure. S. Hassan¹, J.S. Claydon¹, W. Zhang¹, Y. Xu¹, C.D. Damsgaard², J.B. Hansen², C.S. Jacobsen² and G. Van der Laan³ *1. Electronics, University of York, York, United Kingdom; 2. Physics, Technical University of Denmark, Lyngby, Denmark; 3. Daresbury Laboratory, Warrington, United Kingdom*

**MONDAY
MORNING
9:00**

POLIVALENTE

Session A0 TRANSPORT THEORY AND SEMICONDUCTORS SPINTRONICS (POSTER SESSION)

Dafine Ravelosona, Chair
Joerg Wunderlich, Chair

AO-01. Penetration depth of transverse spin current in ferromagnetic metals. T. Tomohiro^{1,2}, Y. Satoshi³, I. Hiroshi¹ and A. Yasuo³ *1. Nanotechnology Research Institute, National Institute for Advanced Industrial Science and Technology, Tsukuba, Japan; 2. Institute of Applied Physics, University of Tsukuba, Tsukuba, Japan; 3. Department of Applied Physics, Graduate School of Engineering, Tohoku University, Sendai, Japan*

AO-02. Effect of Spin Memory Loss at Interfaces of Ferromagnet/Normal Metal on Spin-Transfer Torque. S. Lee¹ and K. Lee¹ *1. Korea University, Seoul, South Korea*

AO-03. Magnetic and structural properties of fully epitaxial Fe₃O₄/MgO/GaAs(100) for spin injection. P. Wong¹, W. Zhang¹, Y. Xu¹ and S.M. Thompson² *1. Spintronics and Nanodevice Laboratory, Department of Electronics, University of York, York, United Kingdom; 2. Department of Physics, University of York, York, United Kingdom*

AO-04. The effect of screening on extracted tunneling barrier parameters. S. Bonetti¹, J. Persson¹ and J. Åkerman¹ *1. Microelectronics and Applied Physics, Royal Institute of Technology (KTH), Kista-Stockholm, Sweden*

AO-05. Rectification effect in the medium with noncoplanar magnetic structure. O.G. Udalov¹ and A.A. Fraerman¹ *1. Institute for physics of microstructures RAS, Nizhny Novgorod, Nizhegorodskaya oblast', Russian Federation*

AO-06. Physical and electrical study of Permalloy/Al₂O₃/Si diodes for spin injection into silicon. N. Bruyan¹, R. Benabderrahmane¹, M. Kanoun¹, C. Baraduc¹, H. Achard² and A. Bsiesy³ *1. SPINTEC, CEA CNRS, Grenoble, France; 2. LETI-Minatec, CEA, Grenoble, France; 3. SPINTEC, Université Joseph Fourier, Grenoble, France*

AO-07. Efficient spin injection and spin filtering in semiconductors by utilizing the *k*²-Dresselhaus spin-orbit effect. T. Fujita^{1,2}, M. Jalil¹ and S. Tan² *1. Electrical and Computer Engineering Department, National University of Singapore, Singapore, Singapore; 2. Data Storage Institute, Singapore, Singapore*

AO-08. Electric field effect on spin diffusion in a semiconductor channel. J. Kwon¹, H. Koo¹, J. Eom^{2,1}, J. Chang¹ and S. Han¹ *1. Center for Spintronics Research, Korea Institute of Science and Technology, Seoul, South Korea; 2. Department of Physics, Sejong University, Seoul, South Korea*

AO-09. Effect of dynamical nuclear polarization on the transport through double quantum dots. J. Inarrea^{1,2} and G. Platero² *1. Fisica, Universidad Carlos III, Leganes, Spain; 2. CSIC, Madrid, Madrid, Spain*

AO-10. Spin Current Characteristics in a Quantum Dot- Ferromagnetic Contacts Sandwich Structure. *W. Chen¹, M. Jalil¹ and S. Tan²1. Electrical & Computer Engineering, National University of Singapore, Singapore, Singapore; 2. Data Storage Institute, Singapore, Singapore*

AO-11. Transport of carbon nanotubes coupled to ferromagnetic electrodes. *S. Sun¹1. Department of Applied Physics, National university of Kaohsiung, Taiwan, Kaohsiung, Taiwan*

AO-12. The Effects of Cotunneling and Spin Flip on The Spin Polarized Transport in A Ferromagnetic Single Electron Tunneling Transistor. *M. Ma¹ and M. Jalil¹1. Department of Electrical and Computer Engineering, Information Storage Materials Laboratory, Singapore, Singapore*

AO-13. Self-sustained spin-polarized current oscillations in diluted magnetic semiconductor superlattices. *R. Escobedo¹, M. Carretero^{2,3}, L.L. Bonilla^{2,3} and G. Platero⁴1. Matemática Aplicada, Universidad de Cantabria, Santander, Cantabria, Spain; 2. G. Milan Institute of Modeling, Simulation and Industrial Mathematics, Universidad Carlos III de Madrid, Leganés, Madrid, Spain; 3. Unidad Asociada al Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Madrid, Spain; 4. Instituto de Ciencia de Materiales, CSIC, Madrid, Madrid, Spain*

AO-14. Modeling of Spin-Transfer Torque in Magnetic Multilayers with Noncollinear Magnetizations. *H. Morise¹ and S. Nakamura¹1. Corp. R&D Ctr., Toshiba Corp., Kawasaki, Kanagawa, Japan*

AO-15. FMR studies of single permalloy layers sandwiched by Al. *H.J. Hurdequint¹, N. Sergeeva¹ and J. Ben Youssef²1. Laboratoire de Physique des Solides, CNRS-Universite Paris-Sud, Orsay, France; 2. Laboratoire de Magnetisme de Bretagne, CNRS-Universite de Bretagne-Ouest, Brest, France*

AO-16. Verifying a sole effect of tunnel barrier on spin transport by spin-polarised photoexcitation. *K. Lee¹, T. Trypiniotis¹, H. Kurebayashi¹, S.N. Holmes^{1,2}, W.S. Cho¹, J.A. Bland¹, K.I. Lee³ and K.H. Shin³1. Physics, Cavendish Laboratory, Cambridge, United Kingdom; 2. Toshiba Research Europe Limited, Toshiba Cambridge Research Laboratory, Cambridge, United Kingdom; 3. Center for Spintronics Research, Korea Institute of Science and Technology, Seoul, South Korea*

AO-17. Polarization dependence of phonon replica peaks in spin-LEDs. *R. Mansell¹, J. Laloë¹, S.N. Holmes², A. Petrou³, I. Farrer¹, G. Jones¹ and T. Bland¹1. Department of Physics, University of Cambridge, Cambridge, United Kingdom; 2. Toshiba Cambridge Research Laboratory, Cambridge, United Kingdom; 3. Department of Physics, SUNY, Buffalo, NY*

AO-18. Comparison of room temperature polymeric spin-valves with different organic components. *D. Dhandapani¹, N.A. Morley¹, A. Rao¹, A. Das², M. Grell² and M.R. Gibbs¹1. Engineering Materials, University of Sheffield, Sheffield, United Kingdom; 2. The Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom*

AO-19. Measurement of the spin polarization of rare earth – transition metal Laves phase compounds by point contact Andreev reflection. *C.G. Morrison¹, K.N. Martin¹, G.J. Bowden¹, P.A. de Groot¹ and R.C. Ward²1. School of Physics and Astronomy, University of Southampton, Southampton, Hampshire, United Kingdom; 2. Clarendon Laboratory, University of Oxford, Oxford, Oxfordshire, United Kingdom*

MAGNETIC NANOCLUSTERS AND NANOPARTICLES I
(POSTER SESSION)**

Marcelo Knobel, Chair

AQ-01. Influence of the capping molecule on the magnetic behavior of thiol capped gold nanoparticles. *P. Crespo¹, E. Guerrero², M. Muñoz-Márquez², A. Hernando¹ and A. Fernández²1. Instituto de Magnetismo Aplicado, Universidad Complutense de Madrid, P.O. Box 28230 Las Rozas, Madrid, Madrid, Spain; 2. Instituto de Ciencia de Materiales de Sevilla, CSIC-US, Av. Américo Vespucio 49, 41092-Sevilla, Sevilla, Spain*

AQ-02. XMCD study of thiol capped Au nanoparticles. V. Bouzas¹, M. Garcia¹, P. Andrea⁴, D. Haskel², G. Ruggeri⁴ and C. de Julian Fernandez³ *1. Dpt. Materials Science, University Complutense, Madrid, Madrid, Spain; 2. Advanced Photon source, Argonne National Laboratory, Argonne, IL; 3. Molecular Magnetism Laboratory, University of Florence, Florence, Florence, Italy; 4. Dpt. of Chemistry and Industrial Chemistry, University of Pisa, Pisa, Pisa, Italy*

AQ-03. Local structure, optical and magnetic studies of Ni nanostructures embedded in SiO₂ matrix by ion implantation. S.K. Sharma¹, R. Kumar², M. Knobel³, P. Kumar⁴, P. Thakur⁵, K.H. Chae⁶, W.K. Choi⁷, D. Kanjilal⁸ and R. Kumar⁹ *1. DFMC, Unicamp, Campinas, SP, Brazil; 2. Materials Science Division, IUAC, New Delhi, Delhi, India; 3. DFMC, Unicamp, SP, Campinas, Brazil; 4. Materials Science Division, IUAC, New Delhi, Delhi, India; 5. Materials Science and Technology Research Division, KIST, Cheongrang, Seoul, Korea, South Korea; 6. Materials Science and Technology Research Division, KIST, Cheongrang, Seoul, Korea, South Korea; 7. Thin Film Materials Research Center, KIST, Cheongrang, Seoul, Korea, South Korea; 8. Materials Science Division, IUAC, New Delhi, Delhi, India; 9. Physics, Ch. Charan Singh University, Meerut, Meerut, India*

AQ-04. Surface contribution to magnetic anisotropy energy in Fe₃O₄ nanoparticles. N. Pérez^{1,2}, P. Guardia^{1,2}, A.G. Roca³, M.P. Morales³, C.J. Serna³, F. Bartolomé⁴, L.M. García^{4,5}, A. Labarta^{1,2} and X. Batlle^{1,2} *1. Física Fonamental, Universitat de Barcelona, Barcelona, Catalunya, Spain; 2. Institut de Nanociència i Nanotecnologia IN2UB, Universitat de Barcelona, Barcelona, Catalunya, Spain; 3. Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Madrid, Spain; 4. Instituto de Ciencia de Materiales de Aragón, CSIC, Zaragoza, Aragón, Spain; 5. Física de la Materia Condensada, Universidad de Zaragoza, Zaragoza, Aragón, Spain*

AQ-05. Microscopic, structural and magnetic investigation of polymer-encapsulated iron oxide nanoparticles. A.R. Rodriguez¹, J.H. Coaquira², J.G. Santos¹, L.B. Silveira¹, E.M. Marmolejo¹, W. Tennpohl¹, J.P. Sinnecker³, M.A. Novak³, D. Rabelo⁴ and P.C. Morais² *1. Physics, Fundação Universidade Federal de Rondônia, Ji-Paraná, RO, Brazil; 2. Physics, Universidade de Brasília, Brasília, DF, Brazil; 3. Physics, Universidade Federal de Rio de Janeiro, Rio de Janeiro, RJ, Brazil; 4. Chemistry, Universidade Federal de Goiás, Goiânia, GO, Brazil*

AQ-06. Magnetite Nanoparticles With No Surface Spin Canting. A. Roca¹, D. Niznansky², M. González-Fernández¹, M. Morales¹ and C. Serna¹ *1. Instituto de Ciencia de Materiales de Madrid (CSIC), Madrid, Spain; 2. Department of Inorganic Chemistry, Charles University, Prague, Czech Republic*

AQ-07. Synthesis and characterization of anisotropic magnetic nanoparticles for lab-on-a-bead applications. N. Kataeva¹, J. Schotter¹ and H. Brueckl¹ *1. Nano-System-Technologies, Austrian Research Centers GmbH, Vienna, Austria*

AQ-08. Magnetic Properties of γ -Fe₂O₃ Nanoparticles Precipitated in Alginate Hydrogels. L.E. Wenger¹, G.M. Tsoi¹, P.P. Vaishnava², R. Naik³, U. Senaratne³, E.C. Buc³ and V.M. Naik⁴ *1. Physics, University of Alabama at Birmingham, Birmingham, AL; 2. Physics, Kettering University, Flint, MI; 3. Physics & Astronomy, Wayne State University, Detroit, MI; 4. Natural Sciences, University of Michigan-Dearborn, Dearborn, MI*

AQ-09. Intermatrix synthesis of magnetic nanocrystals by frontal polymerization and subsequent pyrolysis on iron containing monomer. E.D. Maciejewska¹, M. Leonowicz¹, A. Pomogailo² and G. Dzhardimalieva² *1. Faculty of Material Science and Engineering, Warsaw University of Technology, Warsaw, Poland; 2. Institute of Chemical Physics RAS, Chernogolovka, Russian Federation*

AQ-10. Synthesis of L10 (FePt)1-xAux Nanoparticle Monolayer on Polyimide Substrate. J. Kim¹, R. Kim¹, N. Oh¹, H. An¹, C. Yoon¹, Y. Kim¹ and C. Kim¹ *1. Materials Science and Engineering, Hanyang University, Seoul, South Korea*

AQ-11. Co-CoO Nanoparticles Prepared by Reactive Gas Phase Aggregation. J.A. De Toro¹, J.P. Andrés¹, J.A. González¹, P.S. Normile¹, T. Muñoz¹, P. Muñoz¹, A.J. Barbero¹ and J.M. Riveiro¹ *1. Departamento de Física Aplicada, Universidad de Castilla-La Mancha, Ciudad Real, Spain*

AQ-12. Magnetism of ϵ -Fe₂O₃ nanoparticles modified by Al and Ga substitution. J. Poltíerova Vejpravova¹, P. Brazda², D. Niznansky², S. Danis¹, S. Burianova¹ and V. Sechovsky¹ *1. Faculty of Mathematics and Physics, DCMP, Charles University Prague, Prague 2, Czech Republic; 2. Faculty of Science, DIC, Charles University Prague, Prague 2, Czech Republic*

AQ-13. The first ternary intermetallic Heusler nanoparticles: Co₂FeGa. L. Basit¹, A. Yella¹, S.A. Nepijko², V. Ksenofontov¹, G.H. Fecher¹, W. Tremel¹ and C. Felser¹ *1. Chemistry, Inst. for Inorganic & Analytical Chemistry, Mainz, Germany; 2. Physics, Institute of Physics, Johannes Gutenberg - University, Mainz, Germany*

AQ-14. Giant diamagnetism in AuFe nanoparticles. J. Wu¹, M. Jung², J. Min³, H. Liu^{1,4}, J. Cho³ and Y. Kim³ *1. Institute for Nano Science, Korea University, Seoul 136-713, South Korea; 2. Quantum Materials Research Team, Korea Basic Science Institute, Daejeon 305-333, South Korea; 3. Department of Materials Science and Engineering, Korea University, Seoul 136-713, South Korea; 4. College of Chemistry and Chemical Engineering, Henan University, Kaifeng 475001, China*

AQ-15. XMCD studies of core-shell FeRh nanoparticles. A. Smekhova¹, D. Ciuculescu², F. Wilhelm¹, C. Amiens², A. Rogalev¹ and B. Chaudret² *1. European Synchrotron Radiation Facility, Grenoble, France; 2. Laboratoire de Chimie de Coordination du CNRS, Toulouse, France*

AQ-16. Surface-induced magnetic anisotropy of impurities. A. Szilva¹, L. Szunyogh¹, G. Zarand¹ and C. Muñoz² *1. Department of Theoretical Physics, Budapest University of Technology and Economics, Budapest, Hungary; 2. Instituto de Ciencia de Materiales de Madrid, Consejo Superior de Investigaciones Científicas, Madrid, Spain*

AQ-17. Exchange bias in inverted AFM-core|Fim-shell nanoparticles. G. Salazar-Alvarez¹, A. López-Ortega², J. Sort³, S. Suriñach², M.D. Baró² and J. Nogués⁴ *1. Institut Català de Nanotecnologia, Bellaterra, Barcelona, Spain; 2. Departament de Física, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain; 3. Institució Catalana de Recerca i Estudis Avançats (ICREA) and Departament de Física, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain; 4. Institució Catalana de Recerca i Estudis Avançats (ICREA) and Institut Català de Nanotecnologia, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain*

Session AR SOFT MAGNETIC MATERIALS AND EMC (POSTER SESSION)

Aready Zhukov, Chair

AR-01. Analysis of Conduction Noise Attenuation by Magnetic Composite Sheets on Microstrip Line by Finite Element Method. S. Kim¹, S. Kim¹ and G. Ryu¹ *1. Materials Engineering, Chungbuk National University, Cheongju, South Korea*

AR-02. Microwave Absorbers of Two-layer (Dielectric/Magnetic) Composite Laminates for Wide Oblique Incidence Angles. S. Kim¹ and J. Kim¹ *I. Materials Engineering, Chungbuk National University, Cheongju, South Korea*

AR-03. Left-handed properties in the combined structures of cut-wire pair and continuous wire. V. Dinh Lam¹, J. Kim¹, N. Thanh Tung¹, S. Lee¹ and Y. Lee¹ *I. Hanyang University, Seoul, South Korea*

AR-04. Electromagnetic interference and shielding of valve hall in HVDC converter station. C. Gao¹, Z. Zhao¹ and S. Wang² *1. North China Electric Power University, Baoding, China; 2. Northeast Electric Power Design Institute, Changchun, China*

AR-05. Study of coupling on parallel microstrip lines due to magnetic absorber sheet. V.B. Bregar¹, J. Koselj¹ and B. Drnovsek¹ *1. Nanotesla Institute, Ljubljana, Slovenia*

AR-06. The influence of the construction of secondary reaction plate on the transverse edge effect in Single-sided linear induction motor. S. Lee¹, H. Lee², S. Go¹, K. Kim¹, D. Jung¹ and J. Lee¹ *I. Hanyang university, Seoul, South Korea; 2. Korea Railroad Research Institute, Uiwang, South Korea*

AR-07. RF conduction in-line noise suppression effects for the NiFe and Fe magnetic composite. K. Kim¹, J. Ryu², S. Lee², S. Lee², Y. Choa³ and S. Oh⁴ *I. Physics, Yeungnam University, Gyeongsan, South Korea; 2. Composite Materials, Korea Institute of Materials Science, Changwon, South Korea; 3. Dept. of Chemical Engineering, Hanyang University, Ansan, South Korea; 4. Dept. of Materials Science and Engineering, Seoul National University of Technology, Seoul, South Korea*

AR-08. Optimal bulk content of sulfur for high magnetic induction in inhibitor-free 3% Si-Fe strips. S. Kim¹, J. Soh¹, J. Oh¹, S. Cho¹, S. Han² and N.H. Heo¹ *I. Advanced Materials Group, Korea Electric Power Research Institute, Daejeon, CN, South Korea; 2. Chungnam National University, Daejeon, CN, South Korea*

AR-09. Performance Improvement of PM Synchronous Motor by Using Soft Magnetic Composite Material. G.V. Cvetkovski¹ and L.B. Petkovska¹ *I. Faculty of Electrical Engineering and Information Technologies, Ss. Cyril & Methodius University, Skopje, Macedonia*

AR-10. Magnetic entropy change of V substituted Ni-Mn-Ga Heusler alloy. S. Min¹, Y. Zhang¹, K. Kim^{2,3}, Y. Kim^{2,3}, S. Yu¹, K. Lee⁴ and Y. Kim⁵ *I. BK21 Physics Program and Department of Physics, Chungbuk National University, Cheongju, South Korea; 2. School of Electrical & Computer Engineering, Chungbuk National University, Cheongju, South Korea; 3. CBNU BK21 Chungbuk Information Technology Center, Chungbuk National University, Cheongju, South Korea; 4. Superconductivity Lab., Korea Research Institute of Standard and Science, Taejeon, South Korea; 5. Engineering, Korea Institute of Science and Technology, Seoul, South Korea*

AR-11. Ferroresonance phenomena in electric circuits including amorphous cores. N. Banu¹, E. Barbisio¹, O. Bottauscio², M. Chiampi¹, G. Crotti² and D. Giordano² *I. Ingegneria Elettrica, Politecnico di Torino, Torino, Italy; 2. Electromagnetics, Istituto Nazionale di Ricerca Metrologica, Torino, Italy*

AR-12. Harmonic Distortion of Magnetizing Current in Combined Wound Toroidal Cores. J. Chojnacki¹, P. Liszewski¹, M. Soinski², W. Pluta², R. Rygal², S. Zurek³ and P. Pinkosz⁴ *I. ABB Sp. z o.o., 04-713 Warsaw, Pszasnysz Branch, Poland; 2. Czestochowa University of Technology, Faculty of Electrical Engineering, 42-200 Czestochowa, Poland; 3. Wolfson Centre for Magnetics, School of Engineering, Cardiff University, Cardiff, CF24 2AA, United Kingdom; 4. Magneto Ltd, 42-224 Czestochowa, Poland*

AR-13. The Characterisation of NiFe Cores for High Current Micro-inductors. B. Jamieson¹, T. O'Donnell¹, N. Wang¹, J. Godsell¹ and S. Roy¹ *I. Microsystems Centre, Tyndall National Institute, Cork, Ireland*

FUNDAMENTAL PROPERTIES FOR APPLICATIONS
(POSTER SESSION)**

Roy Chantrell, Chair
Oksana Fesenko Chubykalo, Chair

AT-01. Nature and entropy content of the magnetic transitions in pure and pseudo-binary Laves phases RCo_2 . *M. Parra-Borderías¹, F. Bartolomé¹, J. Herrero-Albillos² and L.M. García¹1. Instituto de Ciencia de Materiales de Aragón, CSIC-Universidad de Zaragoza, Zaragoza, Spain; 2. Department of Materials Science, University of Cambridge, Cambridge, United Kingdom*

AT-02. Estimating magnetic entropy change by a mean-field scaling method and the effect of magnetic irreversibility in first-order transitions. *J.S. Amaral¹, N.O. Silva^{1,2} and V.S. Amaral¹1. Physics and CICECO, Universidade de Aveiro, Aveiro, Portugal; 2. Materia Condensada, Facultad de Ciencias, Zaragoza, Spain*

AT-03. Magnetic and structural phase transitions in magnets with a NaCl structure. *F.A. Kassan-Ogly¹ and B.N. Filippov²1. Department of Theoretical and Mathematical Physics, Institute of Metal Physics, Ekaterinburg, Sverdlovskaya oblast, Russian Federation; 2. Lab. of Micromagnetics, Institute of Metal Physics, Ekaterinburg, Sverdlovsk region, Russian Federation*

AT-04. The magnetic phase transition and electronic properties of CoS_2 -xSex. *M. Otero-Leal², F. Rivadulla¹ and J. Rivas²1. Depto. Química-Física, Universidad de Santiago de Compostela, Santiago de Compostela, La Coruña, Spain; 2. Física Aplicada, Universidad de Santiago de Compostela, Santiago de Compostela, La Coruña, Spain*

AT-05. Symmetry breaking effects in epitaxial magnetic thin films. *E. Jiménez¹, N. Mikuszeit^{1,2}, D. Ecija¹, J. Gallego³, N. Sacristán^{1,4}, J. Vogel², J. Camarero¹ and R. Miranda^{1,6}1. Departamento de Física de la Materia Condensada and Instituto de Materiales “Nicolás Cabrera”, Universidad Autónoma de Madrid, Madrid, Spain; 2. Institut für Angewandte Physik, Universität Hamburg, Hamburg, Germany; 3. Instituto de Ciencia de Materiales de Madrid ICMM, CSIC, Madrid, Spain; 4. Escuela Universitaria de Informática, Universidad de Valladolid, Segovia, Spain; 5. Institut Néel, CNRS, Grenoble, France; 6. Instituto Madrileño de Estudios Avanzados en Nanociencia, IMDEA-Nanociencia, Madrid, Spain*

AT-06. Cobalt doped β -peptide nanotubes: a new class of spintronic materials. *B. Sanyal¹, P.I. Arvidsson^{2,3} and O. Eriksson¹1. Department of Physics, Uppsala University, Uppsala, Sweden; 2. Department of Biochemistry and Organic Chemistry, Uppsala University, Uppsala, Sweden; 3. Discovery CNS & Pain Control, AstraZeneca R&D, Södertälje, Sweden*

AT-07. Magnetotransport Properties of $\text{Y}_{17-x}\text{Fe}_x\text{Co}_x$ Single Crystals. *J. Stankiewicz¹, K.P. Skokov², A.G. Khokhlov², J. Bartolomé¹ and Y.G. Pastushenkov²1. Instituto de Ciencia de Materiales, CSIC - Universidad de Zaragoza, Zaragoza, Spain; 2. Faculty of Physics, Tver State University, Tver, Russian Federation*

AT-08. Weiss oscillations modulated by microwave radiation. *J. Inarrea^{1,2} and G. Platero²1. Physics, Universidad Carlos III, Leganes, Spain; 2. CSIC, Leganes. Madrid, Spain*

AT-09. Nonlinear modulation of spin-orbit interaction in a semiconductor channel. *H. Koo¹, J. Kwon¹, J. Eom^{2,1}, J. Chang¹ and S. Han¹1. Center for Spintronics Research, Korea Institute of Science and Technology, Seoul, South Korea; 2. Department of Physics, Sejong University, Seoul, South Korea*

AT-10. Ordinary Magnetoresistance of Individual Single-Crystalline Bi Nanowires. *J. Ham¹, D. Kim², W. Shim¹, J. Kim¹, K. Lee¹, W. Jeung² and W. Lee¹1. Department of Materials Science and Engineering, Yonsei University, Seoul, South Korea; 2. Division of Material Research, KIST, Seoul, South Korea*

AT-11. The effects of spin relaxation on spin transfer switching of a non-collinear giant magnetoresistance device. *N. Chung^{1,2}, M.B. Abdul Jalil¹, S. Tan², J. Guo¹ and B. AL Sundaram²1. Information Storage Materials Laboratory, Electrical and Computer Engineering Department, National University of Singapore, Singapore, Singapore; 2. Spintronics, Media and Interfaces Division, Data Storage Institute, Singapore, Singapore*

AT-12. Patterning of magnetic structures on austenitic stainless steel by ion beam nitriding. *E. Menéndez¹, A. Martinavicius², M.O. Liedke², G. Abrasonis², J. Fassbender², J. Sort³, S. Suriñach¹, M.D. Baró¹ and J. Nogués⁴1. Physics, Universitat Autònoma de Barcelona, Bellaterra, Spain; 2. Institute of Ion Beam Physics and Materials Research, Forschungszentrum Dresden-Rossendorf, Dresden, Germany; 3. Physics, Institució Catalana de Recerca i Estudis Avançats (ICREA) and Universitat Autònoma de Barcelona, Bellaterra, Spain; 4. Institució Catalana de Recerca i Estudis Avançats (ICREA) and Institut Català de Nanotecnologia, Bellaterra, Spain*

AT-13. Synthesis and characterization of particulate magneto polymer composite at microwave frequencies. *S. Borah¹ and N.S. Bhattacharyya¹1. Physics, Tezpur University, Tezpur, Assam, India*

AT-14. Nanocrystals formation in $\text{Ce}_{100-x}\text{Al}_x$ (x=45, 50) ribbons by rapid solidification from the liquid state. *B. Idzikowski¹, Z. Sniadecki¹ and D. Kaczorowski²1. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland; 2. Institute of Low Temperature and Structure Research, Polish Academy of Sciences, Wroclaw, Poland*

AT-15. Noise enhanced stability of magnetic systems. *M. Trapanese¹1. Dipartimento di Ingegneria Elettrica, Elettronica e delle Telecomunicazioni, University of Palermo, Palermo, Italy*

Roland Groessinger, Chair

AU-01. Implementing mixture design to predict magnetic properties of hybrid bonded magnets. *J. Hsu¹, P. Sharma¹ and A. Verma²1. Physics, National Taiwan University, Taipei, Taiwan; 2. Moserbaer India Ltd, Greater Noida, India*

- AU-02. Establishment of multipole magnetizing method and apparatus using a heating system for Nd-Fe-B isotropic bonded magnets.** *H. Komura¹, M. Kitaoka¹, T. Kiyomiya¹ and Y. Matsuo¹* *1. R & D, FDK Corporation, Kosai, Japan*
- AU-03. Investigation of eddy current loss in divided Nd-Fe-B sintered magnets for synchronous motors due to insulation resistance and frequency.** *K. Yamazaki¹, M. Shina¹, M. Miwa² and J. Hagiwara²* *1. Dept. of Electrical, Electronics and Computer Engineering, Chiba Institute of Technology, Narashino, Chiba, Japan; 2. TDK Corporation, Ichikawa, Chiba, Japan*
- AU-04. Outer Rotor Consequent-pole Bearingless Motor Improved Start-up Characteristics.** *T. Yamada¹, Y. Nakano¹, J. Asama¹, A. Chiba¹, T. Fukao¹, T. Hoshino² and A. Nakajima²* *1. Electrical Engineering, Tokyo University of Science, Chiba, Japan; 2. Japan Aerospace Exploration Agency(JAXA), Tokyo, Japan*
- AU-05. Study of the Static Force by the Difference in the Winding Structure of Permanent Magnet Type Linear Synchronous Motor.** *K. Suzuki¹, Y. Kim² and H. Dohmeki¹* *1. Department of Electrical and Electronic Engineering, Musashi Institute of Technology, Tokyo, Japan; 2. Department of Electrical Engineering, College of Engineering Chosun University, Gwangju, South Korea*
- AU-06. Proposal of the Air-core Type Linear Synchronous Motor Using the Air Levitation System.** *K. Suzuki¹, Y. Kim² and H. Dohmeki¹* *1. Department of Electrical and Electronic Engineering, Musashi Institute of Technology, Tokyo, Japan; 2. Department of Electrical Engineering, College of Engineering Chosun University, Gwanju, South Korea*
- AU-07. Thrust Optimization of Linear Oscillatory Actuator Using Permeance Analysis Method.** *M. Norhisam¹, F. Azhar¹, H. Hashim¹, M. Nirei², H. Wakiwaka³ and A. Razak J.⁴* *1. Electrical & Electronic Engineering Department, Universiti Putra Malaysia, Serdang, Selangor, Malaysia; 2. Faculty of Engineering, Nagano National College of Technology, Tokuma, Nagano, Japan; 3. Faculty of Engineering, Shinshu University, Wakasato Nagano, Japan; 4. Research and Development, Malaysian Palm Oil Board, Kajang, Malaysia*
- AU-08. Optimal design of barrier shape improve torque of interior permanent magnet synchronous motor.** *C. Jin¹ and J. Lee¹* *1. Hanyang University, Seoul, South Korea*
- AU-09. Feasibility Study of a Passive Magnetic Bearing Using the Ring Shaped Permanent Magnets.** *T. Azukizawa¹, S. Yamamoto¹ and N. Matsuo¹* *1. Kobe University, Kobe, Japan*
- AU-10. Design Considerations of Axial Ring magnet.** *C. Li¹, M. Devine¹ and G. Hatch¹* *1. Dexter Magnetic Technologies, Hicksville, NY*

MONDAY
MORNING
9:00

POLIVALENTE

Session AV
INTERMETALLICS AND OTHER HARD MAGNETS
(POSTER SESSION)
Reiko Sato, Chair

- AV-01. Effect of microstructure refinement on magnetic properties of Fe-Pt thin films.** *F.T. Yuan¹, H.W. Huang², W.M. Liao⁴, H.W. Chang¹, D.H. Wei¹, S.K. Chen², Y.D. Yao³ and H.Y. Lee⁴* *1. Institute of Physics, Academia Sinica, Taipei, Taiwan; 2. Materials Science and Engineering, Feng Chia University, Taichung, Taiwan; 3. Material Engineering, Tatung University, Taipei, Taiwan; 4. National Synchrotron Radiation Research Center, Hsinchu, Taiwan*

- AV-02. Magnetization reversal mechanism and intrinsic properties of FePt (110) epitaxial thin films.** *S. Fong^{1,2}, K. Cheng^{1,2}, D. Wei^{1,4}, C. Yu³, C. Lin², F. Yuan¹, H. Chang¹, Y. Liou¹, T. Chin² and Y. Yao⁴* *1. Institute of Physics, Academia Sinica, Taipei, Taiwan; 2. Department of Materials Science and Engineering, National Tsing Hua University, HsinChu, Taiwan; 3. Department of Applied Physics, National University of Kaohsiung, Kaohsiung, Taiwan; 4. Department of Materials Engineering, Tatung University, Taipei, Taiwan*

- AV-03. Effect of Au underlayer on magnetic properties and ordering of CoPt thin films.** *F.T. Yuan¹, H.W. Huang², A.C. Sun³, D.H. Wei¹, H.W. Chang¹, S.K. Chen² and Y.D. Yao⁴* *1. Academia Sinica, Physics, Taipei, Taiwan; 2. Materials Science and Engineering, Feng Chia University, Taichung, Taiwan; 3. Physics, National Taiwan University, Taipei, Taiwan; 4. Materials Engineering, TaTung University, Taipei, Taiwan*

- AV-04. Strain effect on the spin reorientation of epitaxial Nd-Fe-B films.** *A. Kwon¹, V. Neu¹, V. Matias², J. Hänisch², R. Hühne¹, B. Holzapfel¹, L. Schultz¹ and S. Fähler¹* *1. Institute for Metallic Materials, IFW Dresden, Dresden, P.O. Box 270116, D-01171, Germany; 2. Los Alamos national laboratory, NM 87545, NM*

- AV-05. Magnetic properties and structure of Nd-Fe-B thin films with Ta buffer layer prepared on MgO(100) substrate.** *H. Ishioka¹, T. Sato², H. Kato¹, H. Fujino¹ and T. Shima¹* *1. Faculty of Engineering, Tohoku Gakuin University, Tagajo, Japan; 2. Toyota Central R&D Lab, Nagakute, Japan*

- AV-06. In field magnetic domain observation of Nd-Fe-B thin film by magnetic force microscopy.** *T. Iwasa¹, H. Ishioka¹, H. Kato¹, T. Sato² and T. Shima¹* *1. Faculty of Engineering, Tohoku Gakuin University, Tagajo, Japan; 2. Toyota Central R&D Labs., Nagakute, Japan*

- AV-07. Improvement in magnetic properties of PLD-made Nd-Fe-B thick film magnets.** *M. Nakano¹, H. Takeda¹, F. Yamashita², T. Yanai¹ and H. Fukunaga¹* *1. Electronics and Electrical Engineering, Nagasaki University, Nagasaki, Japan; 2. Matsushita Electric Industrial Co., Ltd., Osaka, Japan*

- AV-08. Electrodeposited Co-Pt-(P) thick films prepared by low temperature process.** *T. Tomimatsu¹, M. Nakano¹, T. Yanai¹, N. Fujita² and H. Fukunaga¹* *1. Electronics and Electrical Engineering, Nagasaki University, Nagasaki, Japan; 2. Nara National College of Technology, Yamatokouriyama, Japan*

- AV-09. Some magnetic properties of YTiFe_{11-x}Si_xC carbides.** *B.C. Cizmas¹, L. Bessais² and C. Djega-Mariadassou²* *1. Department of Physics, Transilvania University of Brasov, Brasov, Romania; 2. ICMPE, UMR7182 CNRS, Université de Paris XII, Thiais, France*

- AV-10. A magnetic and Mössbauer spectral study of the Lu(Fe_{1-x}Al_x)₂ compounds.** *C.L. Piquer¹, M. Laguna-Marco^{1,2}, J. Chaboy¹, R. Boada¹ and F. Plazaola²* *1. Instituto de Ciencia de Materiales de Aragón, 50009 Zaragoza, Zaragoza, Spain; 2. Advanced Photon Source, Argonne National Laboratory, 9700 S. Cass Avenue, Argonne 60439, IL; 3. Departamento de Electricidad y Electrónica, Universidad del País Vasco (UPV/EHU), Apartado 644, 48080 Bilbao, Vizcaya, Spain*

- AV-11. Magnetic properties of YCo_xNi_{3-x} compounds.** *E. Burzo¹, R. Tetea¹ and I.G. Deac¹* *1. Faculty of Physics, Babes-Bolyai University, Cluj Napoca, Romania*

AV-12. Magnetostriction in $\text{Sm}_2\text{Fe}_{17}$ before and after nitrogenation. *H. Chen¹, J. Xu¹, Y. Zhang¹, H. Du¹, C. Wang¹ and Y. Yang¹* *1. Physics School, Peking University, Beijing, China*

4:00

AV-13. Magnetic properties of Zr-doped $\text{Lu}_2\text{Fe}_{17}$ single crystal and its hydride. *E. Tereshina^{1,2}, A. Andreev¹ and H. Drulis³* *1. Institute of Physics of the Academy of Sciences of the Czech Republic, Prague, Czech Republic; 2. Department of Condensed Matter Physics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic; 3. Institute of Low Temperature and Structure Research, Wroclaw, Poland*

4:30

AV-14. Crystalline and local structure of SmCo_5 based alloys. *V.P. Menushenkov¹, A.P. Menushenkov², R.V. Chernikov², V.V. Sidorov² and T.A. Sviridova¹* *1. State Technological University "Moscow Institute of Steel and Alloys", Moscow, Russian Federation; 2. Moscow Engineering Physics Institute (State University), Moscow, Russian Federation*

AV-15. Impact of Aluminium on the magnetic properties of RT2 compounds (R = rare-earth, T = transition metal) through the modification of the electronic structure. *R. Boada¹, J. Chaboy¹, M.A. Laguna-Marco^{1,2}, C. Piquer¹ and F. Jiménez-Villacorta³* *1. Física de la Materia Condensada, Instituto de Ciencia de Materiales de Aragón, Zaragoza, Zaragoza, Spain; 2. Advanced Photon Source, Argonne National Laboratory, Chicago, IL; 3. SpLine / Spanish CRG (BM25), European Synchrotron Radiation Facility, Grenoble, France*

MONDAY
AFTERNOON
2:30

AUDITORIO A

Session BA SYMPOSIUM ON THE IMPORTANCE OF GMR

Sarah Thompson, Chair

2:30

BA-01. A History of Magnetic Recording Areal Density Improvements — A Transducer Perspective. *(Invited) R. Fontana¹* *1. IBM Almaden Research Center (retired), San Jose, CA*

3:00

BA-02. The Spin Valve GMR Sensor. *(Invited) B. Gurney¹* *1. San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA*

3:30

BA-03. GMR spin valves, tunneling magnetoresistive devices, and beyond: transport, magnetism, and materials science. *(Invited) O. Heinonen¹, E.W. Singleton¹, B.W. Karr¹, Z. Gao¹, H. Cho¹ and Y. Chen¹* *1. Seagate Technology, Bloomington, MN*

BA-04. GMR and TMR Sensors for non-storage applications. *(Invited) M. Ruehrig¹, G. Rieger¹ and J. Wecker¹* *1. Corporate Technology MMI, Siemens AG, Erlangen, Germany*

BA-05. Spintronic devices for memory and logic applications. *(Invited) B. Dieny¹, R. Sousa¹ and G. Prenat¹* *1. SPINTEC, CEA/CNRS/UJF/INPG, Grenoble, France*

MONDAY
AFTERNOON
2:30

MADRID

Session BB HEAD-MEDIA INTERFACE AND TRIBOLOGY -I

Bo Liu, Chair

2:30

BB-01. A dynamic scratch test to study read/write head degradation due to head disk interactions. *A. Wallash¹, H. Zhu¹ and D. Chen²* *1. Advanced Technology, Hitachi GST, San Jose, CA; 2. Mechanical Engineering Department, UC Berkeley, Berkeley, CA*

2:45

BB-02. Effect of Segregant Surface Energy on PMR Media Roughness. *Q. Dai¹, H. Do¹, K. Takano¹ and B. Marchon¹* *1. Hitachi GST, San Jose, CA*

3:00

BB-03. Stress Induced Permanent Magnetic Signal Degradation of PMR System. *S. Lee¹, S. Hong¹, N. Kim¹, J. Ferber¹, X. Che¹ and B.D. Strom²* *1. Samsung Information Systems America, San Jose, CA; 2. Apple Inc., Cupertino, CA*

3:15

BB-04. Scratch Induced Demagnetization of Perpendicular Magnetic Disk. *M. Furukawa¹, J. Xu¹, Y. Shimizu¹ and Y. Kato¹* *1. Central Research Laboratory, Hitachi, Ltd., Fujisawa-shi, Kanagawa-ken, Japan*

3:30

BB-05. Lubricant dynamics on a slider: “the waterfall effect” *B. Marchon*¹, *X. Guo*¹, *A. Moser*¹, *R. Kroeker*² and *F. Crimi*² *1. San Jose Research Center, Hitachi GST, San Jose, CA; 2. Server Business Unit, Hitachi GST, San Jose, CA*

3:45

BB-06. Effect of Thermal Bonding on Frictional Properties of Monolayer Lubricant Films Coated on Magnetic Disk Surfaces. *H. Zhang*¹, *Y. Mitsuya*², *A. Fuwa*¹, *Y. Fujikawa*¹ and *K. Fukuzawa*¹ *1. Nagoya University, Nagoya, Japan; 2. Nagoya Industrial Science Research Institute, Nagoya, Japan*

4:00

BB-07. Experimental Comparisons of Spreading and Replenishment Flows of Molecularly Thin Lubricant Films Coated on Magnetic Disks. *Y. Mitsuya*¹, *H. Zhang*², *J. Ohgi*² and *K. Fukuzawa*² *1. Nagoya Industrial Science Research Institute, Nagoya, Japan; 2. Micro-Nano Systems Engineering, Nagoya University, Nagoya, Japan*

4:15

BB-08. Coverage Analysis of Molecularly Thin Lubricant Films using Molecular Dynamics Simulations and CAICISS Measurements. *Y. Ikai*¹, *N. Nakamura*¹, *H. Chiba*¹ and *T. Imamura*¹ *1. Fujitsu Laboratories Ltd., Atsugi 243-0197, Japan*

4:30

BB-09. Time Dependence of Head-Media Interference at Low Fly Heights. *J. He*¹, *J. Hopkins*¹, *S. Duan*¹ and *K. Johnson*¹ *1. HGST, San Jose, CA*

4:45

BB-10. Air bearing surface designs for less humidity sensitivity. *S. Zhang*¹, *G. Tyndall*¹ and *M. Suk*¹ *1. Advanced Technology, Samsung Information Systems America, San Jose, CA*

MONDAY
AFTERNOON
2:30

ROMA

Session BC MEMS AND MINIATURE MAGNETIC SENSORS

Eckhard Quandt, Chair

2:30

BC-01. Electroplated Co-rich CoPt thick films and patterned arrays for magnetic MEMS. *N. Wang*^{1,2} and *D.P. Arnold*¹ *1. Interdisciplinary Microsystems Group, Dept. of Electrical and Computer Engineering, University of Florida, Gainesville, FL; 2. Materials Science and Engineering, University of Florida, Gainesville, FL*

2:45

BC-02. Optical technique for measuring magnetic MEMS vibrations. *V. de Manuel*¹, *R. del Real*², *M. Diaz-Michelena*³, *I. Arruego*⁴, *I. Lucas*⁵ and *H. Guerrero*⁶ *1. Space Programs and Space Sciences, INTA, Torrejón de Ardoz, Madrid, Spain; 2. Space Programs and Space Sciences, INTA, Torrejón de Ardoz, Madrid, Spain; 3. Space Programs and Space Sciences, INTA, Torrejón de Ardoz, Madrid, Spain; 4. Space Programs and Space Sciences, INTA, Torrejón de Ardoz, Madrid, Spain; 5. Space Programs and Space Sciences, INTA, Torrejón de Ardoz, Madrid, Spain; 6. Space Programs and Space Sciences, INTA, Torrejón de Ardoz, Madrid, Spain*

3:00

BC-03. Design of Axial Flux Machine for Micro Flywheel Energy Storage System. *J. Yi*¹, *K.W. Lee*², *S. Jeong*², *M. Noh*¹ and *S.S. Lee*² *1. Mechatronics Engineering, Chungnam National University, Daejeon, South Korea; 2. Mechanical Engineering, KAIST, Deajeon, South Korea*

3:15

BC-04. Magnetic hysteresis loop micro sensor for wafer level testing of magnetic films. *E. Flick*¹, *K. Feindt*² and *H.H. Gatzert*¹ *1. Leibniz Universitaet Hannover, Institute for Microtechnology, Garbsen, Germany; 2. innomas GmbH, Ilmenau, Germany*

3:30

BC-05. Thin Film Magneto-Impedance Sensor Integrated with L-10 FePt Thin Film Bias Magnet. *K. Ohmori*¹, *K. Tan*², *K. Itoi*¹, *K. Nagasu*¹, *Y. Uemichi*¹, *T. Aizawa*¹ and *R. Yamauchi*¹ *1. Microdevice department, Electron Device laboratory, Fujikura Ltd., Sakura, Chiba, Japan; 2. Akita research institute of advanced technology(AIT), Akita, Japan*

3:45

BC-06. PWM Type Amorphous Wire CMOS IC Magneto-Impedance Sensor Having High Temperature Stability. *Y. Nakamura*¹, *T. Uchiyama*¹, *C.M. Cai*² and *K. Mohri*³ *1. Nagoya University, Nagoya, Japan; 2. Aichi Steel Co., Tokai, Japan; 3. Aichi Micro Intelligent Co., Tokai, Japan*

4:00

BC-07. Microfabrication process and characteristics of thin-film noise suppressor integrated onto the re-wiring layer of a LSI chip. *M. Yamaguchi*¹, *T. Fukushima*¹, *T. Akiba*² and *A. Nakamura*² *1. Dept. of Electrical and Communication Engineering, Tohoku University, Sendai, Miyagi, Japan; 2. Division of Process & Device Analysis Engineering Development, Renesas Technology Corp., Kodaira, Tokyo, Japan*

4:15

BC-08. Investigation of Magneto Impedance Sensors in Micro Scale for an Application to Chip-cytometer. *D. Kim^{1,2}, H. Kim¹, D. Chun¹, W. Lee² and W. Jeung¹* *1. Functional Materials Research Center, Korea Institute of Science and Technology, Seoul, South Korea; 2. Material Science & Engineering, Yonsei University, Seoul, South Korea*

4:30

BC-09. Development of Low Noise GMI Sensor and Its Applications. *H. Aoyama¹, M. Yamamoto¹, Y. Honkura¹ and K. Sumi²* *1. Electronic & magnetic product division, Aichi Steel Corporation, Tokai, Aichi, Japan; 2. Toyota Central Research Laboratory, Nagakute, Aichi, Japan*

4:45

BC-10. 3-Axis Compact Electric Compass Using Maneto-Impedance Sensor. *M. Yamamoto¹ and Y. Honkura¹* *1. Aichi Steel Corporation, Aichi-ken, Japan*

MONDAY
AFTERNOON
2:30

PARIS

Session BD MAGNETIC SENSORS II

Joachim Wecker, Chair

2:30

BD-01. Giant magnetoresistive sensors for DNA microarray. *L. Xu¹, H. Yu², S. Han¹, S. Osterfeld¹, R.L. White¹, N. Pourmand² and S.X. Wang¹* *1. Materials Science and Engineering, Stanford University, Stanford, CA; 2. Stanford Genome Technology Center, Stanford University, Palo Alto, CA*

2:45

BD-02. Device for individualized detection of articles containing magnetic microwires based on ferromagnetic resonance. *P. Marín^{1,2}, D. Cortina³, J. Calvo³ and A. Hernando^{1,2}* *1. Instituto de Magnetismo Aplicado, Universidad Complutense de Madrid, Las Rozas, Madrid, Spain; 2. Departamento de Física de Materiales, Universidad Complutense de Madrid, Madrid, Spain; 3. Micromag 2000, S.L., Las Rozas, Spain*

3:00

BD-03. Two-domain model for orthogonal fluxgate. *M. Butta¹ and P. Ripka¹* *1. CVUT v Praze - FEL - MagLab, Praha, Czech Republic*

3:15

BD-04. Fabrication and characterization of magnetic tunnel junction field sensors with a Co₂MnSi thin film. *M. Masuda¹, T. Uemura¹, K. Matsuda¹ and M. Yamamoto¹* *1. Division of Electronics for Informatics, Graduate School of Information Science and Technology, Hokkaido University, Sapporo, Japan*

3:30

BD-05. High sensitive thin film wattmeter using magnetic thin film. *H. Tsujimoto¹, H. Toratani¹ and Y. Deguti¹* *1. Faculty of Engineering, Osaka City University, Osaka, Japan*

3:45

BD-06. Acoustic Interferometer Based on Magnetostrictive Delay Lines. *C. Petridis¹, V. Vassiliou¹, M. Kollár² and E. Hristoforou¹* *1. Mining and Metallurgy Engineering, National Technical University of Athens, Athens, Greece; 2. Electrical Engineering and Information Technology, Slovak University of Technology in Bratislava, Bratislava, Slovakia*

4:00

BD-07. 2D magnetic sensor based on planar Hall effect and surface nano-structuration. *J. Briones¹, F. Montaigne¹, M. Hehn¹, G. Lengaigne¹ and D. Lacour¹* *1. Laboratoire de Physique des Matériaux, Nancy-University, CNRS, Vandoeuvre lès Nancy, France*

4:15

BD-08. Advanced Techniques for Modelling and Detection of Cracks in Hot Wire Steel. *R. Marklein¹ and M. Rahman¹* *1. Department of Electrical Engineering and Computer Science, University of Kassel, Kassel, Germany*

4:30

BD-09. Thermally modulated flux concentrator for minimizing 1/f noise in magnetic sensors. *W. Wang¹ and Z. Jiang¹* *1. Electrical Engineering, University of Wisconsin - Milwaukee, Milwaukee, WI*

4:45

BD-10. Nanoscale InAs Hall Crosses Excited with Localized Magnetic and Electric Fields. *L. Folks¹, A.S. Troup², T.D. Boone¹, J.A. Katine¹, G.J. Sullivan³, M. Field³, E. Marinero¹ and B.A. Gurney¹* *1. San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA; 2. Hitachi Cambridge Laboratory, Cambridge, United Kingdom; 3. Teledyne Scientific Company, Thousand Oaks, CA*

MONDAY
AFTERNOON
2:30

LONDRES

4:00

Session BE
MOLECULAR AND NOVEL MATERIALS-I

Fernando Palacio, Chair

2:30

BE-01. Field dependence of the magnetocaloric effect beyond the mean field approach: a universal curve for the magnetic entropy change. (Invited) *V. Franco*¹ and *A. Conde*¹ *1. Department of Condensed Matter Physics, Sevilla University, Sevilla, Spain*

3:00

BE-02. Isothermal and adiabatic measurements and modeling of sign switching magnetocaloric effect in NiMnSn. *L. Giudici*^{1,2}, *C.P. Sasso*¹, *M. Kuepferling*¹, *M. Pasquale*¹ and *V. Basso*¹ *1. Electromagnetism Department, INRIM, Torino, Italy; 2. Physics Department, Politecnico di Torino, Torino, Italy*

3:15

BE-03. Magnetocaloric properties of La(Fe,Co,Si)₁₃ bulk material prepared by powder metallurgy. *M. Katter*¹, *V. Zellmann*¹, *G. Reppel*¹ and *K. Uestuener*¹ *1. Vacuumschmelze GmbH & Co. KG, Hanau, Germany*

3:30

BE-04. Magnetocaloric Properties and Structure of the Gd₅Ge_{1.8}Si_{1.8}Sn_{0.4} Compound. *V. Provenzano*¹, *T. Zhang*^{1,2}, *A.J. Shapiro*¹, *Y.G. Chen*² and *R.D. Shull*¹ *1. Magnetic Materials Group, NIST, Gaithersburg, MD; 2. School of Materials Science and Engineering, Sichuan University, Chengdu, China*

3:45

BE-05. Ferromagnetism in graphite induced by ion irradiation. *M.A. Ramos*¹, *A. Climent-Font*², *A. Muñoz-Martin*², *M. Garcia-Hernandez*³, *A. Asenjo*³ and *P.D. Esquinazi*^{2,4} *1. Fisica de la Materia Condensada, Universidad Autonoma Madrid, Madrid, Spain; 2. Centro de Microanalisis de Madrid (CMAM), Universidad Autonoma Madrid, Madrid, Spain; 3. Instituto de Ciencia de Materiales de Madrid (ICMM), Consejo Superior de Investigaciones Cientificas (CSIC), Madrid, Spain; 4. Superconductivity and Magnetism Division, Institut für Experimentelle Physik II, Fakultät für Physik und Geowissenschaften, University of Leipzig, Leipzig, Germany*

BE-06. Magnetic properties of TiO₂/γ-Fe₂O₃ nanocomposites designed for photocatalytic applications. *V. Sechovsky*¹, *V. Tyrpekl*², *J. Poltiero*¹, *S. Danis*¹, *B. Bittova*¹ and *D. Niznansky*² *1. Department of Condensed Matter Physics, Charles University in Prague, Prague 2, Czech Republic; 2. DIC, Charles University Prague, Prague, Czech Republic*

4:15

BE-07. Elastic model for complex hysteresis in molecular magnets. *C. Enachescu*¹, *L. Stoleriu*¹, *A. Stancu*¹ and *A. Hauser*² *1. Department of Physics, Alexandru Ioan Cuza University, Iasi, Romania; 2. Department of Physical Chemistry, Universite de Geneve, Geneva, Switzerland*

4:30

BE-08. Various relaxation behaviors in one dimensional chain-like molecular magnet [Fe^{II}(Δ)Fe^{II}(Λ)(ox)₂(phen)₂]_n at low temperature. *J. Her*^{1,3}, *C. Sun*^{1,3}, *C. Chou*^{1,3}, *C. Chan*^{1,3}, *C. Lin*^{1,3}, *H. Yang*^{1,3}, *L. Li*^{2,4}, *K. Lin*^{2,4} and *S. Taran*^{1,3} *1. Department of Physics, National Sun Yat-sen University, Kaohsiung, Taiwan; 2. Department of Chemistry, National Chung-Hsing University, Taichung, Taiwan; 3. Center for Nanoscience and Nanotechnology, National Sun Yat-sen University, Kaohsiung, Taiwan; 4. Center of Nanoscience and Nanotechnology, National Chung-Hsing University, Taichung, Taiwan*

MONDAY
AFTERNOON
2:30

BERLIN

Session BF
MAGNETIC SEMICONDUCTORS -I

Jodseph Fontcuberta, Chair

2:30

BF-01. Study of the origin of the spin polarization in the Co-doped (La,Sr)TiO₃ diluted magnetic oxide. *O. Copie*¹, *G. Herranz*¹, *M. Bibes*¹, *R. Mattana*¹, *F. Petroff*¹, *K. Bouzehouane*¹, *H. Jaffres*¹, *E. Jacquet*¹, *J. Maurice*¹, *V. Cros*¹, *M. Basletic*², *E. Tafari*², *A. Hamzic*², *A. Barthelemy*¹ and *P. Bencok*³ *1. Unité Mixte de Physique CNRS THALES, Palaiseau, France; 2. Department of Physics, Faculty of Science, University of Zagreb, Zagreb, Croatia; 3. European Synchrotron Radiation Facility, Grenoble, France*

2:45

BF-02. Ultrafast laser spectroscopy of GaMnAs. *E. Rozkotová*¹, *P. Horodyská*¹, *P. Němec*¹, *D. Sprinzl*¹, *F. Trojánek*¹, *P. Malý*¹, *V. Novák*², *K. Olejník*², *M. Cukr*² and *T. Jungwirth*² *1. Faculty of Mathematics and Physics, Charles University in Prague, Prague, Czech Republic; 2. Institute of Physics, AS CR, Prague, Czech Republic*

3:00

BF-03. Preparation and properties of cobalt doped ZnO nanowires. *I. Enculescu¹, E. Matei¹, M. Sima¹, S. Granville², J. Ansermet² and R. Neumann³* *1. National Institute for Materials Physics, Magurele, Ilfov, Romania; 2. Institut de Physique des Nanostructures, EPFL, Lausanne, Switzerland; 3. Materials Research, GSI, Darmstadt, Germany*

3:15

BF-04. Room temperature ferromagnetism of FeCo-codoped ZnO nanorods prepared by chemical vapor deposition. *J. Chen¹, Y. Yan², J. Liu¹, M. Yu¹, A. West¹ and W. Zhou¹* *1. Advanced Materials Research Institute, University of New Orleans, New Orleans, LA; 2. National Renewable Energy Laboratory, Golden, CO*

3:30

BF-05. Magnetic interactions in (Zn,Co)O - effects of heat treatment and co-doping. *M. Wikberg¹, P. Svedlindh¹, V. Coleman^{2,3}, R. Knut², O. Karis², D. Iusan², B. Sanyal² and G. Westin³* *1. Engineering Sciences, Uppsala University, Uppsala, Sweden; 2. Physics, Uppsala University, Uppsala, Sweden; 3. Materials Chemistry, Uppsala University, Uppsala, Sweden*

3:45

BF-06. Growth of Zn_{1-x}Mn_xO nanorod arrays in aqueous solution. *Y. Fang¹, J. Persson¹, M. Göthelid¹ and J. Åkerman¹* *1. Department of Microelectronics and Applied Physics, Royal Institute of Technology, Stockholm-Kista, Sweden*

4:00

BF-07. Investigation of ferromagnetism in N and Mn co-sputtered ZnO. *J. Persson¹, S. Bonetti¹, M. Göthelid¹, O. Tjernberg¹, J. Åkerman¹, M. Wikberg² and O. Karis²* *1. Material Physics, KTH, Kista, Sweden; 2. Departement of physics, Uppsala University, Uppsala, Sweden*

4:15

BF-08. Andreev and Optical Measurement of Spin polarisation in ZnO Based Dilute Magnetic Semiconductors. *J.R. Neal¹, K. Yates², A.J. Behan¹, D.S. Score¹, H.J. Blythe¹, A.M. Fox¹, L.F. Cohen² and G.A. Gehring¹* *1. Physics and Astronomy, The University of Sheffield, Sheffield, United Kingdom; 2. Blackett Laboratory, Imperial College, London, United Kingdom*

4:30

BF-09. Magnetic behaviour of Fe implanted TiO₂ thin films. *R. Sanz¹, M. Hernandez-Vélez^{1,2}, T. Kubart³, D. Martín³ and J. Jensen³* *1. Department of optical, magnetic and transport properties, Instituto de Ciencia de Materiales, CSIC, Madrid, Spain; 2. Fisica Aplicada, Universidad Autónoma, Madrid, Spain; 3. Department of Engineering Sciences, Ångström Laboratory, Uppsala University, Uppsala, Sweden*

4:45

BF-10. (Ga,Mn)As ultrathin films with high Mn concentration. *J. Deng^{1,2}, W. Wang¹, L. Chen¹, J. Lu¹, Y. Ji¹ and J. Zhao¹* *1. Institute of Semiconductors, Chinese Academy of Sciences, Beijing, China; 2. Department of Physics, University of Science and Technology of China, Hefei, China*

MONDAY
AFTERNOON
2:30

AMSTERDAM

Session BG
MICROWAVE MATERIALS AND DEVICES I
Nian-Xiang Sun, Chair

2:30

BG-01. Non-resonant parametric recovery of spin-wave signals. *S. Schäfer¹, A.V. Chumak¹, A.A. Serga¹ and B. Hillebrands¹* *1. Fachbereich Physik and Forschungsschwerpunkt MINAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany*

2:45

BG-02. Reflectivity of microwave signal in ferromagnetic wires. *A. Yamaguchi^{1,2}, N. Higashio¹, K. Motoi¹, T. Kishimoto¹ and H. Miyajima¹* *1. Department of Physics, Keio University, Yokohama, Kanagawa, Japan; 2. PRESTO, Tokyo, Japan*

3:00

BG-03. Ferromagnetic resonance on FeSiB thin films displaying spin reorientation transition. *M. Coisson¹, F. Celegato¹, P. Tiberto¹ and F. Vinai¹* *1. Electromagnetics, INRIM, Torino, TO, Italy*

3:15

BG-04. Correlation receiver of below-noise pulsed signals based on the parametric interactions of spin waves in magnetic films. *G.A. Melkov¹, V.I. Vasyuchka¹, V.A. Moiseienko¹ and A.N. Slavin²* *1. Faculty of Radiophysics, Kiev National Taras Shevchenko University, Kiev, Ukraine; 2. Department of Physics, Oakland University, Rochester, MI*

3:30

BG-05. Electronically Tunable Miniaturized Antennas on Magnetoelectric Substrates with Enhanced Performance. *N. Sun¹, G. Yang¹, A. Daigle¹, J. Lou¹, M. Liu¹, O. Obi¹, S. Stoute¹, C. Pettiford¹, J. Wang¹ and K. Naishadham²* *1. Electrical and Computer Eng., Northeastern University, Boston, MA; 2. RF communications Groups, Draper Laboratory, Cambridge, MA*

3:45

BG-06. On the study of left handed coplanar waveguide zeroth order resonator on ferrite substrate. *M.A. Abdalla¹ and Z. Hu¹ I. School of Electrical and Electronic Engineering, University of Manchester, Manchester, United Kingdom*

4:00

BG-07. Observation of bright and dark spin wave envelope solitons in periodic magnetic film structures. *A. Ustinov¹, N. Grigorieva¹ and B. Kalinikos¹ I. Physical Electronics and Technology, St.Petersburg Electrotechnical University, St.Petersburg, Russian Federation*

4:15

BG-08. Measurement System of FMR Linewidth ΔH_{eff} of Ferrite using a Shorted Stripline. *S. Takeda¹ and H. Suzuki² I. Magnontech, Ltd., Kumagaya, Japan; 2. KEYCOM Corp., Tokyo, Japan*

4:30

BG-09. On the study of ferrite coupled coplanar waveguide. *M.A. Abdalla¹ and Z. Hu¹ I. School of Electrical and Electronic Engineering, University of Manchester, Manchester, United Kingdom*

MONDAY
AFTERNOON
2:30

CARACAS

Session BH MULTILAYER FILMS AND SUPERLATTICES I

A. Cebollada, Chair

2:30

BH-01. (110)-textured La₂/3Ca/1/3MnO₃ thin films. Optimal electrodes in manganite tunnel junctions. *I.C. Infante¹, F. Sánchez¹, J. Fontcuberta¹, M. Wojcik², E. Jedryka², S. Estradé³, F. Peiró³, J. Arbiol^{3,4}, V. Laukhin⁵ and J.P. Espinós⁶ I. Magnetic Materials and their Applications, Institut de Ciència de Materials de Barcelona, Bellaterra, Barcelona, Spain; 2. Institute of Physics, Polish Academy of Sciences, Warszawa, Warszawa, Poland; 3. Dept. d'Electrònica, EME/CeRMAE/IN2UB, Universitat de Barcelona, Barcelona, Barcelona, Spain; 4. TEM-MAT, Serveis Científicotècnics, Universitat de Barcelona, Barcelona, Barcelona, Spain; 5. Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Barcelona, Spain; 6. Instituto de Ciencia de Materiales de Sevilla ICMSE (CSIC-USE), Sevilla, Sevilla, Spain*

2:45

BH-02. Observation of large tunneling magnetoresistance in Fe-MgO-Fe epitaxial multilayers using STM double tunneling experiments. *J. Lee^{1,2}, C. Krafft² and R.D. Gomez^{1,2} I. Electrical and Computer Engineering, University of Maryland, College Park, MD; 2. Laboratory for Physical Sciences, College Park, MD*

3:00

BH-03. Multifunctional Ni/Au Multilayered Nanowires. *M. Cho¹, J. Cho^{2,3}, J. Wu⁴, J. Min², J. Lee², B. An² and Y. Kim² I. Program in Micro/Nano System, Korea University, Seoul, South Korea; 2. Department of Materials Science and Engineering, Korea University, Seoul, South Korea; 3. Korea Electronic Technology Institute, Korea University, Gyeonggi, South Korea; 4. Institute for Nano Science, Korea University, Seoul, South Korea*

3:15

BH-04. Novel phenomena in multi-layer composite structure observed by anomalous Hall effect measurement. *S. Das¹, T. Ichihara¹, H. Suzuki¹ and Y. Matsuda² I. Central Research Laboratory, Hitachi Ltd., Odawara, Kanagawa, Japan; 2. Head Development, Hitachi Global Storage Technologies, Odawara, Kanagawa, Japan*

3:30

BH-05. Band and bubble domains in AF coupled [Co/Pt]/Ru multilayers. *C. Bran^{1,2}, O. Hellwig³, U. Wolff¹, L. Schultz¹ and V. Neu¹ I. IFW Dresden, Dresden, Germany; 2. IMPRS "Dynamical Processes in Atoms, Molecules and Solids", Dresden, Germany; 3. Hitachi Global Storage Technologies, San Jose, CA*

3:45

BH-06. Exchange-spring behavior in Fe-FePt thin films studied via synchrotron radiation. *B. Laenens¹, N. Planckaert¹, J. Demeter¹, K. Temst¹, A. Vantomme¹, C. Strohm², R. Rüffer² and J. Meersschant¹ I. Instituut voor Kern- en Stralingsfysica and INPAC, Katholieke Universiteit Leuven, Celestijnenlaan 200D, B-3001 Leuven, Belgium; 2. ESRF, Rue Jules Horowitz 6, Boîte Postale 220 38043 Grenoble, France*

4:00

BH-07. How to retrieve more information on magnetic films from microwave permeability measurements. *O. Acher¹, V. Dubuget^{1,2} and S. Dubourg¹ I. Département Matériaux, CEA, Monts, France; 2. UMR 6157 LEMA, Tours, France*

4:15

BH-08. The effect of FePt layer on the transition temperature of FeRh layer. *N.T. Nguyen¹, Y.Y. Hnin¹ and T. Suzuki¹* *1. Information Storage Materials Laboratory, Toyota Technological Institute, Nagoya, Japan*

4:30

BH-09. Effects of perpendicular interlayer coupling on canting angles of TbCo sublattice magnetization by x-ray magnetic circular dichroism. *M. Lin¹, P. Huang¹, Y. Wu¹, H. Hou¹, C. Lai¹, H. Lin² and F. Chang²* *1. Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan; 2. National Synchrotron Radiation Research Center, Hsinchu, Taiwan*

4:45

BH-10. Magnetization reversal in thermally processed Fe/SmCo spring magnets. *J.E. Davies¹, Y. Choi², J.P. Liu³, J.S. Jiang², S.D. Bader², R.D. Shull¹ and K. Liu⁴* *1. Metallurgy/Magnetic Materials, NIST, Gaithersburg, MD; 2. Materials Science Division, Argonne National Laboratory, Argonne, IL; 3. Physics Department, University of Texas, Arlington, TX; 4. Physics Department, University of California, Davis, CA*

MONDAY
AFTERNOON
5:10

AUDITORIO A

Session YA
NOBEL PRIZE CELEBRATION
Manuel Vazquez, Chair

TUESDAY
MORNING
9:30

AUDITORIO A

Session CA
SYMPOSIUM ON BIOMEDICAL APPLICATIONS
Axel Hoffman, Chair

9:30

CA-01. Non-invasive Measurement of Tissue Iron Concentrations with Magnetic Resonance Imaging. *(Invited) T.G. St Pierre¹* *1. School of Physics, University of Western Australia, Perth, WA, Australia*

10:00

CA-02. Exploring the frontiers of magnetic nanoparticles prepared in microemulsions: from ferrofluids to biomedical applications. *(Invited) J. Rivas^{1,2} and M. Lopez Quintela^{2,1}* *1. Laboratory of Magnetism and Nanotechnology(NANOMAG), University of Santiago de Compostela, Santiago de Compostela, A Coruña, Spain; 2. Laboratory of Magnetism and Nanotechnology(NANOMAG), University of Santiago de Compostela, Santiago de Compostela, A Coruña, Spain*

10:30

CA-03. Spintronic biochips for biomolecular recognition detection. *(Invited) P. Freitas^{1,2}, V. Martins^{1,3}, F. Cardoso^{1,2}, S. Cardoso¹, V. Chu¹, J. Conde^{1,3}, J. Loureiro^{1,2}, J. Germano^{5,4}, L. Sousa^{5,4} and M. Piedade^{5,4}* *1. INESC MN, Lisbon, Portugal; 2. Physics Department, Instituto Superior Tecnico, Lisbon, Portugal; 3. Chemical and Bioengineering Department, Instituto Superior Tecnico, Lisbon, Portugal; 4. Electrical Engineering Department, Instituto Superior Tecnico, Lisbon, Portugal; 5. INESC ID, LISBON, Portugal*

11:00

CA-04. In vivo sensing, moving and heating of magnetic nanoparticles in the human body. *(Invited) Q. Pankhurst¹* *1. London Centre for Nanotechnology, London, United Kingdom*

11:30

CA-05. Room-temperature detection of single magnetic biomolecular labels with Hall devices*. *(Invited) G. Mihajlovic¹, K. Aledealat², P. Xiong², S. von Molnár², M. Field³, G.J. Sullivan³, K. Ohtani⁴ and H. Ohno⁴* *1. Materials Science Division, Argonne National Laboratory, Argonne, IL; 2. Center for Materials Research and Technology (MARTECH) and Department of Physics, Florida State University, Tallahassee, FL; 3. Teledyne Scientific Company LLC, Thousand Oaks, CA; 4. Laboratory for Electronics Intelligent Systems, Research Institute of Electrical Communication, Tohoku University, Sendai, Japan*

TUESDAY
MORNING
9:30

MADRID

Session CB
SPIN TORQUE OSCILLATORS - I
Andrew Kent, Chair

9:30

CB-01. Spin transfer induced microwave emission and spin diode effects in MgO based magnetic tunnel junctions. *B. Georges¹, V. Cros¹, J. Grollier¹, A. Fert¹, A. Fukushima², H. Kubota², K. Yakushiji², S. Yuasa² and K. Ando²* *1. UMR CNRS-Thales, Palaiseau, France; 2. National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan*

9:45

CB-02. Quantized spin wave modes in magnetic tunnel junctions. *A. Helmer*¹, T. Devolder¹, J. Hayakawa^{2,3}, K. Ito², H. Takahashi², S. Ikeda³, P. Crozat¹, J.V. Kim¹, C. Chappert¹ and H. Ohno³ *1. Institut d'Electronique Fondamentale, Université Paris-Sud, Orsay, France; 2. Advanced Research Laboratory, Hitachi, Ltd, Tokyo, Japan; 3. Laboratory for Nanoelectronics and Spintronics, Research Institute of Electrical Communication, Tohoku University, Sendai, Japan*

10:00

CB-03. Low field spin-transfer induced precession in a pinned SAF layer for high frequency devices. *A.M. Deac*^{1,3}, W.H. Rippard¹ and J.A. Katine² *1. NIST, Boulder, CO; 2. Hitachi San Jose Research Center, San Jose, CA; 3. Institut fuer Festkoerperforschung, Forschungszentrum Juelich GmbH, Juelich, Germany*

10:15

CB-04. Spin-polarized current induced excitations in a synthetic antiferromagnet. *D. Gusakova*^{1,2}, D. Houssameddine¹, U. Ebels¹, M. Cyril², B. Dieny¹ and L. Buda-Prejbeanu¹ *1. SPINTEC URA 2512, Grenoble, France; 2. 2LIMN/DIHS/LETI CEA-Grenoble, Grenoble, France*

10:30

CB-05. Tuning the Coherence of Spin-Torque-Driven Dynamics in Nanomagnetic Oscillators. (Invited) *K. Thadani*¹, G. Finocchio³, Z.P. Li², O. Ozatay², J.C. Sankey¹, I.N. Krivorotov⁴, Y.T. Cui², R.A. Buhrman² and D.C. Ralph¹ *1. Physics, Cornell University, Ithaca, NY; 2. Applied & Engineering Physics, Cornell University, Ithaca, NY; 3. University of Messina, Messina, Italy; 4. University of California-Irvine, Irvine, CA*

11:00

CB-06. Phase locking of a Spin Transfer Oscillator to an external microwave current : a milestone for the synchronization of a large assembly of STOs. *B. GEORGES*¹, J. Grollier¹, M. Darques¹, V. Cros¹, C. Deranlot¹, G. Faini² and A. Fert¹ *1. Unité Mixte de Physique CNRS/Thales (CNRS-UMR137), Palaiseau, France; 2. Phynano team, Laboratoire de Photonique et Nanostructures, LPN - CNRS, Marcoussis, France*

11:15

CB-07. Magnetic point-contact precession frequency vs. magnetic field angle – The prospect for spin torque oscillator operation at 65 GHz. S. Bonetti¹, J. Persson¹, F.B. Mancoff² and J. Åkerman¹ *1. Microelectronics and Applied Physics, Royal Institute of Technology (KTH), Kista-Stockholm, Sweden; 2. Technology Solutions Organization, Freescale Semiconductor Inc., Chandler, AZ*

11:30

CB-08. Asymmetric lineshapes in spin-torque nano-oscillators near threshold. *J. Kim*¹, Q. Mistral¹, C. Chappert¹, V.S. Tiberkevich² and A.N. Slavin² *1. Institut d'Electronique Fondamentale, CNRS / Univ. Paris Sud, Orsay, France; 2. Department of Physics, Oakland University, Rochester, MI*

11:45

CB-09. Experimental and theoretical study of spin-torque microwave excitation linewidths in nanocontacts subject to out-of-plane external fields. *M. Pasquale*¹, C. Serpico², P. Anzalone³, G. Bertotti¹, M. Pufall⁴ and W. Rippard⁴ *1. Divisione Elettromagnetismo, INRIM, Torino, Italy; 2. Dipartimento di Ingegneria Elettrica, Università di Napoli "Federico II", Napoli, Italy; 3. Dipartimento di Ingegneria Elettrica Industriale, Politecnico di Torino, Torino, Italy; 4. Electromagnetics Division, NIST, Boulder, CO*

12:00

CB-10. The frequency of microwave oscillation on domain wall magnetoresistance elements. *H. Endo*¹, K. Shirafuji¹, H. Suzuki¹, M. Doi¹, M. Takagishi², H.N. Fuke², H. Iwasaki² and M. Sahashi¹ *1. Department of Electronic Engineering, Tohoku University, Sendai, Japan; 2. Corporate Research & Development Center, Toshiba Corporation, Kawasaki, Japan*

12:15

CB-11. Spin wave Doppler shift. *V. Vlaminck*¹ and M. Bailleul¹ *1. GEMME, IPCMS, Strasbourg, France*

TUESDAY
MORNING
9:30

ROMA

Session CC MgO MAGNETIC TUNNEL JUNCTIONS I

Bernard Dieny, Chair

9:30

CC-01. Equilibrium and out-of-equilibrium spintronic phenomena in single crystal MgO based magnetic tunnel junctions. (Invited) *C. Tiusan*¹, F. Greullet¹, F. Bonell¹, M. Hehn¹, S. Andrieu¹, C. Bellouard¹, F. Montaigne¹, D. Halley², M. Bowen², W. Weber², E. Snoeck³, F. Aliev⁴, E. Popova⁵ and A. Schuhl^{6,1} *1. Nancy Université- CNRS, Laboratoire de Physique des Matériaux - UMR7556, Vandoeuvre les Nancy, Lorraine, France; 2. Institut de Physique et Chimie des Matériaux, Strasbourg, Alsace, France; 3. CEMES, Toulouse, France; 4. University of Madrid, Madrid, Spain; 5. Université de Versailles, Laboratoire de Magnétisme et d'Optique de Versailles, Versailles, France; 6. SPINTEC, Grenoble, France*

10:00

CC-02. Nature of Voltage Dependence of Spin Transfer Torque in Magnetic Tunnel Junctions. (Invited) *M. Chshiev*¹, I. Theodonis^{2,3}, N. Kioussis², A. Kalitsov² and W. Butler¹ *1. Center for Materials for Information Technology, University of Alabama, Tuscaloosa, AL; 2. Department of Physics and Astronomy, California State University, Northridge, CA; 3. Department of Physics, National Technical University, Zografou, Athens, Greece*

10:30

CC-03. Magnetic tunnelling junctions based on MgO(001) epitaxial barriers: from the interfacial spin dependent electronic structure to the ultimate TMR. *A. Cattoni*¹, D. Petti¹, M. Cantoni¹, S. Brivio¹ and R. Bertacco¹ *1. Center LNESS - Department of Physics, Politecnico di Milano, Como, Italy*

10:45

CC-04. Magnetic Tunnel Junctions with MgO Tunnel Barriers and NiFeSiB/CoFeB Hybrid Free Layers. *J. Cho*¹, D. Kim¹, T. Wang¹, S. Isogami², M. Tsunoda², M. Takahashi² and Y. Kim¹ *1. Department of Materials Science and Engineering, Korea University, Seoul, South Korea; 2. Department of Electronic Engineering, Tohoku University, Sendai, Japan*

11:00

CC-05. The Surface Electronic Structure: a Key Parameter in Low Resistance Area Single Crystal Magnetic Tunnel Junctions. *P. Zermatten*¹, M. Miron¹, G. Gaudin¹, A. Schuhl¹, F. Greullet², M. Hehn² and C. Tiusan² *1. SPINTEC, CEA/CNRS, Grenoble, France; 2. LPM, CNRS/UHP, Nancy, France*

11:15

CC-06. Transport characterization of the single and double magnetic tunnel junctions using point contact spectroscopy. *A. Iovan*¹, S. Cherepov¹, A. von Bieren¹, S. Andersson¹ and V. Korenivski¹ *1. Nanostructure Physics, KTH, Stockholm, Sweden*

11:30

CC-07. Magnetotransport properties of MgO-based epitaxial magnetic tunnel junctions with a nonmagnetic electrode. *R. Matsumoto*^{1,2}, A. Fukushima¹, T. Nagahama¹, Y. Suzuki^{1,2}, K. Ando¹ and S. Yuasa¹ *1. Nanoelectronics Research Institute, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan; 2. Graduate School of Engineering Science, Osaka University, Toyonaka, Japan*

11:45

CC-08. High bias tunneling magnetoresistance and low frequency noise in fully epitaxial Fe/C/MgO/Fe(001) magnetic tunnel junctions. *D. Herranz*¹, R. Guerrero¹, R. Villar¹, *F.G. Aliev*¹, F. Greullet², C. Tiusan² and M. Hehn² *1. Fisica Materia Condensada, CIII, Universidad Autonoma de Madrid, Madrid, Madrid, Spain; 2. Laboratoire de Physique des Matériaux, Nancy Université, Nancy, France*

12:00

CC-09. 1/f magnetic noise dependence on free layer thickness in linear MgO magnetic tunnel junctions. *P. Wisniowski*¹, J.M. Almeida¹ and P.P. Freitas¹ *1. INESC-MN, Lisbon, Portugal*

12:15

CC-10. Hybrid Magnetic Tunnel Junction-MEMS device for 1/f noise suppression. *A.A. Guedes*^{1,2}, S.B. Patil¹, P. Wisniowski¹, V. Chu¹, J.P. Conde^{1,2} and P.P. Freitas^{1,2} *1. INESC-MN, Lisbon, Portugal; 2. Instituto Superior Tecnico, Lisbon, Portugal*

TUESDAY
MORNING
9:30

PARIS

Session CD MAGNETIC MICROSCOPY I

Amanda Petford-Long, Chair

9:30

CD-01. Field driven ferromagnetic phase evolution originating from the domain boundaries in antiferromagnetically coupled perpendicular anisotropy films. *T. Hauet*¹, C.M. Günther², O. Hovorka³, A. Berger³, M. Im⁴, P. Fischer⁴ and O. Hellwig¹ *1. Hitachi Gst, San Jose, CA; 2. BESSY mbH, Berlin, Germany; 3. CIC NanoGUNE Consolider, Donostia, Spain; 4. Center for X-Ray Optics, Lawrence Berkeley National Laboratory, Berkeley, CA*

9:45

CD-02. Magnetization indicator film for Lorentz transmission electron microscopy measurements of perpendicularly magnetized nanostructures. *J.W. Lau*¹ *1. Metallurgy Division, National Institute of Standards and Technology, Gaithersburg, MD*

10:00

CD-03. Effect of in-situ FIB trimming on the spin configurations of hexagonal shaped ferromagnetic elements. *S.Y. Lua*^{1,3}, S.S. Kushvaha², Y. Wu², K. Teo² and T. Chong³ *1. NUS Graduate School for Integrative Sciences and Engineering, National University of Singapore, Singapore, Singapore; 2. Department of Electrical and Computer Engineering, National University of Singapore, Singapore, Singapore; 3. Data Storage Institute, Singapore, Singapore*

10:15

CD-04. Ballistic electron magnetic microscopy on Co/Cu/NiFe spin valves. *A. Kaidatzis*¹, S. Rohart¹, A. Thiaville¹ and J. Miltat¹ *1. Laboratoire de Physique des Solides, Orsay, France*

10:30

CD-05. Mapping Atomic-Scale Spin Structures on Insulators by Magnetic Exchange Force Microscopy. (Invited) *R.M. Wiesendanger*¹ *1. Institute of Applied Physics, University of Hamburg, Hamburg, Germany*

11:00

CD-06. 120° antiferromagnetic Néel structure of Mn monolayer on Ag(111). *C. Gao*¹, W. Wulfhekel^{1,2} and J. Kirschner¹ *1. Max Planck Institute of Microstructure Physics, Halle (Saale), Germany; 2. Physikalisches Institut, Universität Karlsruhe (TH), Karlsruhe, Germany*

11:15

CD-07. The role of the spin-orientation of the tip in spin-polarized scanning tunneling microscopy in external magnetic fields. *D. Sander*¹, G. Rodary¹, S. Wedekind¹ and J. Kirschner¹ *1. Max Planck Institute, Halle, Germany*

11:30

CD-08. Theoretical description of the high-frequency magnetic force microscopy (HF-MFM) technique. *M.R. Koblishcka*¹ and U. Hartmann¹ *1. Institute of Experimental Physics, University of the Saarland, Saarbrücken, Germany*

11:45

CD-09. Imaging a single domain wall position by Extraordinary Hall Effect in nanostructured thin films with perpendicular anisotropy. *M. Miron*¹, P. Zermatten¹, G. Gaudin¹ and S. Alain¹ *1. SPINTEC (CNRS/CEA), Grenoble, France*

12:00

CD-10. Hall imaging of the history dependence of the magneto-caloric effect in Gd₅Si₂0.09Ge_{1.91}. *M. Kuepferling*¹, J. Moore², V. Basso¹, C.P. Sasso¹, L. Giudici¹ and L. Cohen² *1. Department for Electromagnetism, National Institute of Metrological Research, Torino, Italy; 2. The Blackett Laboratory, Imperial College of Science, London, United Kingdom*

12:15

CD-11. Imaging perpendicularly recorded data with servo feedback control. *C. Tseng*¹, P. McAvoy¹, I.D. Mayergoyz¹ and C. Krafft² *1. Department of Electrical and Computer Engineering, University of Maryland, College Park, MD; 2. Laboratory for Physical Sciences, College Park, MD*

TUESDAY
MORNING
9:30

LONDRES

Session CE
EXCHANGE BIAS I
Josep Nogues, Chair

9:30

CE-01. Reversible exchange bias in ideal antiferromagnetic alloys. *D. Lederman*¹ and M. Cheon¹ *1. Department of Physics, West Virginia University, Morgantown, WV*

9:45

CE-02. Role of anisotropies on the asymmetric magnetization reversal behavior in exchange-biased systems. *E. Jiménez*¹, *J. Camarero*¹, *J. Sort*², *J. Nogués*³, *N. Mikuszeit*^{1,4}, *J. García-Martín*⁵, *A. Hoffmann*⁶, *B. Dieny*⁷ and *R. Miranda*^{1,8} *1. Departamento de Física de la Materia Condensada and Instituto de Materiales “Nicolás Cabrera”, Universidad Autónoma de Madrid, Madrid, Spain; 2. Departament de Física, Institució Catalana de Recerca i Estudis Avançats (ICREA) and Universitat Autònoma de Barcelona, Bellaterra, Spain; 3. Institució Catalana de Recerca i Estudis Avançats (ICREA) and Institut Català de Nanotecnologia, Bellaterra, Spain; 4. Institut für Angewandte Physik, Universität Hamburg, Hamburg, Germany; 5. Instituto de Microelectrónica de Madrid CNM-CSIC, Tres Cantos, Spain; 6. Materials Science Division and Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL; 7. SPINTEC, URA2512, CNRS/CEA, Grenoble, France; 8. Instituto Madrileño de Estudios Avanzados en Nanociencia IMDEA-Nanociencia, Madrid, Spain*

10:00

CE-03. Asymmetric magnetization reversal behavior in exchange-biased multilayers in different antiferromagnetic thickness ranges. *D. Spenato¹, V. Castel¹, S.P. Pogossian¹, C. Le Graët¹, D.T. Dekadjevi¹ and J. Ben Youssef¹* *1. Laboratoire de Magnétisme de Bretagne, CNRS/FRE 2997, Université de Bretagne Occidentale, Brest, France*

10:15

CE-04. Tailoring of dynamic magnetic properties of ferromagnetic thin films by ultra-thin IrMn layers. *J. McCord¹, R. Kaltofen² and L. Schultz¹* *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany; 2. Institute for Integrative Nanosciences, IFW Dresden, Dresden, Germany*

10:30

CE-05. Local magnetization studies by Magnetic Force and Kerr microscopy of exchange bias in Co/CoO patterned dots. *U. Wolff¹, S. Suck², D. Givord², J. McCord¹, L. Schultz¹ and V. Neu¹* *1. IFW Dresden, Dresden, Germany; 2. Institut Neel, Grenoble, France*

10:45

CE-06. Control of crystallographic orientation in IrMn/CoFe exchange bias systems. *N. Aley¹, G. Vallejo-Fernandez¹, K. O'Grady¹, B. Lafferty², J. Agnew² and Y. Lu²* *1. Physics, University of York, York, United Kingdom; 2. Seagate Technology Ltd., Derry, United Kingdom*

11:00

CE-07. Magnetoresistance in positive and negative exchange bias Ni/FeF₂ bilayered 200 nm antidots. *M. Kovalina^{1,2}, R. Morales^{3,4}, J. Villegas⁴, M. Erekhinsky⁴, I.V. Roshchin⁴, A. Labarta^{1,2}, I.K. Schuller⁴ and X. Batlle^{1,2}* *1. Fisica Fundamental, Universidad de Barcelona, Barcelona, Barcelona, Spain; 2. Institut de Nanociència i Nanotecnologia (IN2UB), Barcelona, Barcelona, Spain; 3. Departamento de Física, Universidad de Oviedo, Oviedo, Oviedo, Spain; 4. Physics Department, University of California-San Diego, San Diego, CA*

11:15

CE-08. Exchange coupled IrMn/CoFe networks on mesoporous alumina. *N.N. Shams¹, M. Rahman¹ and C. Lai¹* *1. Materials Science and Engineering, National Tsing-Hua University, Hsinchu, Taiwan*

11:30

CE-09. Effects of nonmagnetic additives in metallic antiferromagnets on exchange bias. *M. Fecioru-Morariu¹, S. Ali¹, C. Papusoi², M. Sperlich¹ and G. Güntherodt¹* *1. Physikalisches Institut (IIA), RWTH Aachen University, Aachen, Germany; 2. SPINTEC, CEA/CNRS, Grenoble, France*

11:45

CE-10. Negative and positive exchange bias in polycrystalline Ni/FeF₂ thin films. *R. Morales^{1,2}, J. Alameda¹ and I. Schuller²* *1. Dpto. de Física, Universidad de Oviedo, Oviedo, Spain; 2. Physics Department, University of California San Diego, La Jolla, CA*

12:00

CE-11. Large exchange bias IrMn/CoFe for magnetic tunnel junctions. *L.E. Fernandez-Outon¹, K. O'Grady¹, M. Zhou² and M. Pakala²* *1. Physics, The University of York, York, United Kingdom; 2. Western Digital Fremont Inc., Fremont, CA*

12:15

CE-12. Observation of Metastable Remanence States in Pinned Antiferromagnetically Coupled Ferromagnetic Layers. *K. Srinivasan¹, S. Wong¹, S.N. Piramanayagam¹ and R. Sbiaa¹* *1. Spintronics, Media and Interface Division, Data Storage Institute, A*STAR, Singapore, Singapore*

TUESDAY
MORNING
9:30

BERLIN

Session CF ELECTRICAL STEELS AND INDUCTOR CORES Anthony Moses, Chair

9:30

CF-01. Effect of hot and cold rolling on grain size and texture in FeSi strips with a Si-content larger than 2 wt%. *P.R. Calvillo¹, H. Hermann², J. Verstraete¹, J. Schneider^{1,2} and Y. Houbaert¹* *1. Metallurgy and Materials Science, Universiteit Gent, Gent-Zwijnaarde, Belgium; 2. Institut für Metallformung, Technische Universität Bergakademie Freiberg, Freiberg, Germany*

9:45

CF-02. Magnetization processes of Fe(Si,Al)-steels with homogeneous and inhomogeneous distribution of (Si,Al). *J. Schneider¹, J. Verstraete¹, K. Verbeken¹ and Y. Houbaert¹* *1. Metallurgy and Materials Science, Universiteit Gent, Gent-Zwijnaarde, Belgium*

10:00

CF-03. Effects of Si content on the magnetic properties of Fe-Si alloy powder cores. *P. Jang¹, B. Lee¹ and I. Jeong²* *1. Div. of Applied Science, Cheongju University, Cheongju, Chungcheongbuk-do, South Korea; 2. R&D Center, Changsung Corp., Incheon, South Korea*

10:15

CF-04. An In-depth Study of the Barkhausen Emission Signal Properties of the Plastically Deformed Fe-2%Si Alloy. *L. Piotrowski¹, B. Augustyniak¹, M. Chmielewski¹ and F.J. Landgraf²* *1. Dept. of Appl. Phys. and Math., Gdansk University of Technology, Gdansk, Poland; 2. Dept. of Met. Eng., University of Sao Paulo, Sao Paulo, Brazil*

10:30

CF-05. Correlation between core loss and microstructure for Fe-Si powder cores. *S. Takemoto¹ and T. Saito¹* *1. R&D Center, Daido Steel, Nagoya, Japan*

10:45

CF-06. Effect of surface magnetic domain structure on iron loss of thin-gauged 3% si-fe sheets. *H. Jung¹, J. Kim¹ and S. Kim²* *1. Metallurgy and Material Science, Hanyang University, Ansan, South Korea; 2. Machinery and Materials Group, Korea Electric Power Research Institute, Taejeon, South Korea*

11:00

CF-07. Specific total loss components under axial magnetization in electrical steel sheets with different degree of Goss texture. *W. Pluta¹* *1. Electrical Engineering Faculty, Czestochowa University of Technology, Czestochowa, Poland*

11:15

CF-08. Three Dimensional Polycrystal Magnetic Field Analysis of Electrical Steel. *K. Fujisaki^{1,2}* *1. Technical Development Bureau, Nippon Steel Corporation, Futtsu-city, Chiba-prefecture, Japan; 2. Graduate School of Environmetal Studies, Tohoku University, Sendai, Japan*

11:30

CF-09. Improvement of the Bertotti's formula for energy loss in soft magnetic materials. *K. Sokalski¹ and J. Szczyglowski¹* *1. TU Czestochowa, Czestochowa, Poland*

11:45

CF-10. Influence of improving efficiency using Fe-P-B-Nb type ultra low loss glassy metal dust core on inductor for large-current. *H. Matsumoto¹, Y. Yamada¹ and A. Urata¹* *1. RESEARCH AND DEVELOPMENT UNIT, NEC TOKIN, Sendai, Japan*

12:00

CF-11. Soft-magnetic Fe-based nanocrystalline thick ribbons. *M. Lee¹, C. Lin¹, S. Wang¹ and T. Chin²* *1. Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan; 2. Department of Materials Science and Engineering, Feng Chia University, Taichung, Taiwan*

12:15

CF-12. Gas flow effects to the magnetic properties of current annealed Vitroperm samples. *V. de Manuel¹ and R. Pérez del Real²* *1. Space Programs and Space Sciences, INTA, Torrejón de Ardoz, Madrid, Spain; 2. Space Programs and Space Sciences, INTA, Torrejón de Ardoz, Madrid, Spain*

TUESDAY
MORNING
9:30

AMSTERDAM

Session CG

THIN FILMS: SURFACE AND ANISOTROPY PROPERTIES

Fernando Briones, Chair

9:30

CG-01. Routes to Create Ultrathin Co Films with Perpendicular Magnetic Easy Axis. *S. Gallego¹ and C. Muñoz¹* *1. Inst. Ciencia Materiales Madrid, Madrid, Spain*

9:45

CG-02. Perpendicular magnetic anisotropy at Co/Oxide interfaces. *Y. Dahmane¹, S. Auffret¹, U. Ebels¹, B. Rodmacq¹ and B. Dieny¹* *1. CEA Grenoble, Grenoble, France*

10:00

CG-03. Giant magnetic anisotropy of Fe₃Pt alloy thin films with various crystallographical orientations. *H. Yamamoto¹ and T. Suzuki¹* *1. Information Storage Materials Laboratory, Toyota Technological Institute, Nagoya, Japan*

10:15

CG-04. Uniaxial anisotropy and temperature driven magnetization reversal of Fe deposited on a MnAs/GaAs(001) magnetic template. *R. Breitwieser², M. Marangolo¹, M. Sacchi^{2,3}, C. Spezzani⁴, L. Coelho⁵, J. Milano⁶, V. Etgens¹, J. Lüning² and N. Jaouen³* *1. INSP, Université Pierre et Marie Curie, Paris, France; 2. Laboratoire de Chimie Physique - Matière et Rayonnement, UPMC - Univ.Paris 6, Paris, France; 3. Synchrotron SOLEIL, Paris, France; 4. Sincrotrone Trieste S.C.p.A, Trieste, Italy; 5. Universidade Federal de Minas Gerais, Minas Gerais, Brazil; 6. Centro Atómico Bariloche and Instituto Balseiro-UNCuyo, CNEA, Bariloche, Argentina*

10:30

CG-05. Magnetic anisotropy control by ion irradiation. *A. Mougin¹, H. Cruguel², C. Beigné³, A. Marty³, J. Ferré¹, Y. Samson³, O. Plantevin², F. Fortuna² and H. Bernas²* *1. LPS, Univ. Paris Sud, UMR CNRS 8502, Orsay, France; 2. CSNSM, Univ. Paris-Sud, UMR CNRS 8609, Orsay, France; 3. DRFMC/SP2M, CEA, Grenoble, France*

10:45

CG-06. Study of magnetic structures on the nanoscale: a multiscale approach based on first principles calculations. *L. Szunyogh¹, L. Udvardi¹, A. Antal¹, B. Lazarovits^{2,1} and B. Újfalussy²* *1. Department of Theoretical Physics, Budapest University of Technology and Economics, Budapest, Hungary; 2. Research Institute of Solid State Physics and Optics, Hungarian Academy of Sciences, Budapest, Hungary*

11:00

CG-07. Magneto optic sensing using ultrathin ferromagnetic films. *E. Liskova¹ and S. Visnovsky¹* *1. Institute of Physics, Charles University, Prague, Czech Republic*

11:15

CG-08. Nonuniform RKKY magnetism in nanosized films, wires and spheres. *E. Meilikhov¹ and R. Farzetdinova¹* *1. Kurchatov Institute, Moscow, Russian Federation*

11:30

CG-09. Spin Dynamics of Ge:Mn Thin Films. *O. Kazakova¹, R. Morgunov², M. Farle³ and L. Ottaviano⁴* *1. NPL, Teddington, United Kingdom; 2. IPCP, Chernogolovka, Russian Federation; 3. Universitat Duisburg-Essen, Duisburg, Germany; 4. Università dell'Aquila, Coppito L'Aquila, Italy*

11:45

CG-10. Magnetoelastic coupling in epitaxial monolayers: The role of lattice strain. *D. Sander¹, Z. Tian¹ and J. Kirschner¹* *1. Max Planck Institute, Halle, Germany*

12:00

CG-11. Spin-reorientation transitions induced by coinage-metal capping of Co/Ru(0001) studied by spin-polarized low energy electron microscopy. *F. El Gabaly^{1,2}, A.K. Schmid², K.F. McCarty³ and J. de la Figuera^{4,1}* *1. Centro de Microanálisis de Materiales, Universidad Autónoma de Madrid, Madrid, Madrid, Spain; 2. Berkeley National Laboratory, Berkeley, CA; 3. Sandia National Laboratories, Livermore, CA; 4. Instituto de Química-Física Rocasolano, CSIC, Madrid, Madrid, Spain*

12:15

CG-12. Magnetic Properties of Single-Crystalline FeRh Alloy Thin Films. *S. Inoue¹, Y.Y. Hnin¹, N.T. Nguyen¹ and T. Suzuki¹* *1. Information Storage Materials Laboratory, Toyota Technological Institute, Nagoya, Japan*

TUESDAY
MORNING
9:30

CARACAS

Session CH MAGNETIC SHAPE MEMORY ALLOYS

Thomas Lograsso, Chair

9:30

CH-01. Controlling the microstructure in Ni-Mn-Ga alloys. *M. Pötschke¹, F. Thoss¹, U. Gaitzsch¹, C. Hürrieh¹, S. Roth¹, B. Rellinghaus¹ and L. Schultz¹* *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany*

9:45

CH-02. Field, stress and temperature control of the phase transitions in Ni₅₅Mn₂₀Ga₂₅ single crystal. *C.P. Sasso¹, M. Pasquale¹ and L. Giudici^{1,2}* *1. Electromagnetics, INRiM, Torino, Italy; 2. Physics, Politecnico di Torino, Turin, Italy*

10:00

CH-03. Effect of annealing conditions on the structure formation in NiMnGa shape memory alloys. *R. Wroblewski¹ and M. Leonowicz¹* *1. Faculty of Materials Science and Engineering, Warsaw University of Technology, Warsaw, Poland*

10:15

CH-04. Magnetic-field induced strain in 5M polycrystalline alloy. *U. Gaitzsch¹, C. Huerrich¹, M. Pötschke¹, S. Roth¹ and L. Schultz¹* *1. Inst metal mater, IFW Dresden, Dresden, Germany*

10:30

CH-05. Angular dependence of magnetic shape memory effect – model and experiment. *O. Heczko^{1,2}* *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany; 2. Laboratory of Materials Science, Helsinki University of Technology, Helsinki, Finland*

10:45

CH-06. Magnetic properties of rapidly quenched Ni-Mn-Ga wires. *C. Gomez-Polo*¹, J. Pérez-Landazábal¹, V. Recarte¹, V. Sánchez-Alarcos¹ and G. Badini²*1. Dept. Física, Universidad Publica de Navarra, Pamplona, Spain; 2. Instituto de Ciencia de Materiales, CSIC, Madrid, Spain*

11:00

CH-07. Comparative study of structural and magnetic properties of bulk and powder Ni₅₂Fe₁₇Ga₂₇Co₄ magnetic shape memory alloy. *J. Liu*¹, N. Scheerbaum¹, D. Hinz¹ and O. Gutfleisch¹*1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany*

11:15

CH-08. Magnetocaloric effect and martensitic transition in Ni-Mn-In alloys under hydrostatic pressure. *J. Lyubina*¹, O. Gutfleisch¹, K. Nenkov¹, L. Mañosa², X. Moya², A. Planes², M. Barrio³, J. Tamarit³, S. Aksoy⁴, T. Krenke⁴ and M. Acet⁴*1. Institute for Metallic Materials, IFW Dresden, P.O. Box 270116, D-01171 Dresden, Germany; 2. Facultat de Física, Dept. d'Estructura i Constituents de la Materia, Universitat de Barcelona, Diagonal 647, E-08028 Barcelona, Spain; 3. Dept. de Física i Enginyeria Nuclear, Universitat Politècnica de Catalunya, Diagonal 647, 08028-Barcelona, Spain; 4. Experimentalphysik, Universität Duisburg-Essen, D-47048 Duisburg, Germany*

11:30

CH-09. Magnetic domain reorganization and twin boundary dynamics in magnetic shape memory alloys. (Invited) *J. McCord*¹*1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany*

12:00

CH-10. Exchange bias in Ni-rich ferromagnetic shape memory alloys Ni-Mn-Sn. *V. Khovaylo*¹, V. Koledov¹, V. Shavrov¹, A. Korolyov², M. Ohtsuka³, H. Miki⁴ and T. Takagi⁴*1. Institute of Radioengineering and Electronics, Moscow, Russian Federation; 2. Institute of Metal Physics, Ekaterinburg, Russian Federation; 3. Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, Sendai, Japan; 4. Institute of Fluid Science, Tohoku University, Sendai, Japan*

12:15

CH-11. Magnetic and shape memory properties of FeMnSi-based glass-coated microwires. *H. Chiriac*¹, *N. Lupu*¹, C.M. Craciunescu², S. Corodeanu¹ and M. Grigoras¹*1. Magnetic Materials and Devices, National Institute of Research and Development for Technical Physics, Iasi, Romania; 2. "Politehnica" University, Timisoara, Romania*

TUESDAY
MORNING
9:00

POLIVALENTE

Session CL
PERMANENT MAGNET MACHINES I
(POSTER SESSION)
Phil Anderson, Chair

CL-01. Analytical computation and experimental verification of magnetic core loss of permanent magnet generator considering the wind turbine speed. *S. Jang*¹, *K. Ko*¹, *J. Choi*¹ and *H. Cho*²*1. Chungnam Nat'l Univ, Daejeon, South Korea; 2. Korea Institute of Machinery & Materials, Daejeon, South Korea*

CL-02. Stator core loss prediction in large synchronous machines. *A. Knight*¹, *S. Troitskaia*¹ and *Y. Zhan*¹*1. Electrical and Computer Eng, University of Alberta, Edmonton, AB, Canada*

CL-03. Design and analysis of ultra high-speed permanent magnet generator driven by gas turbine for micro scale power generation. *S. Jang*¹, *K. Ko*¹, *J. Choi*¹ and *Y. Lee*²*1. Chungnam Nat'l Univ, Daejeon, South Korea; 2. Korea Institute of Science of Technology, Seoul, South Korea*

CL-04. Electromagnetic Performance Analysis and Vector Control of a Flux-Controllable Stator-PM Brushless Motor with Skewed Rotor. *M. Cheng*¹, *X. Zhu*^{1,2}, *W. Hua*¹ and *H. Jia*¹*1. School of Electrical Engineering, Southeast University, Nanjing, China; 2. School of Electrical Information Engineering, Jiangsu University, Zhenjiang, China*

CL-05. Permanent magnet optimization for reduction of cogging torque of BLDC motor using response surface methodology. *J. Lee*¹, *H. Shim*¹ and *S. Wang*¹*1. Mechatronics, Gwangju Institute of Science and Technology, Gwangju, South Korea*

CL-06. Design of Direct-Coupled, Small Scaled Permanent Magnet Generators for Wind Turbines. *S. Jang*¹, *H. Kim*¹, *J. Choi*¹, *D. You*¹, *S. Lee*² and *B. Kim*³*1. Chungnam National University, Daejeon, South Korea; 2. Korea Institute of Industrial Technaology, Kwangju, South Korea; 3. Korea Electric Power Research Institute, Daejeon, South Korea*

CL-07. Design and experimental evaluation of synchronous machine without iron loss using double-sided halbach magnetized permanent magnet rotor in high power fess. *D. You*¹, *S. Jang*¹, *K. Ko*¹ and *S. Choi*²*1. chungnam national univ., daejeon, South Korea; 2. Korea Institute of Machinery and Materials, Daejeon, South Korea*

CL-08. Experimental method for determining magnetically nonlinear characteristics of electric machines with magnetically nonlinear and anisotropic iron core, damping windings and permanent magnets. *G. Stumberger*^{1,2}, *T. Marcic*², *B. Stumberger*^{1,2} and *D. Dolinar*¹*1. Faculty of electrical engineering and computer science, University of Maribor, Maribor, Slovenia; 2. TECES, Maribor, Slovenia*

CL-09. Detent force minimization of permanent magnet linear synchronous motor by means of two different methods. *Y. Zhu*¹ and *Y. Cho*¹*1. Electrical Engineering, Dong-A University, Busan, South Korea*

CL-10. A STUDY ON THE IRREVERSIBLE MAGNET DEMAGNETIZATION IN SINGLE-PHASE LINE-START PERMANENT MAGNET RELUCTANCE MOTOR. J. Hong², H. Nam³ and T. Kim¹. *1. Electrical Engineering, Gyeongsang National University, Jinju, South Korea; 2. Hanyang University, Seoul, South Korea; 3. LG Electronics, Changwon, South Korea*

CL-11. Design of IPM type BLDC motor considering demagnetization characteristics. B. Yang¹, S. Hong¹ and B. Kwon¹. *1. Hanyang Univ., Ansan, South Korea*

CL-12. Characteristic analysis of Permanent Magnet Motor Considering Anisotropic Characteristics of Electrical Steel Sheets. S. Kwon¹, J. Lee¹, K. Ha² and J. Hong¹. *1. Department of Mechanical Engineering, Hanyang University, Seoul, South Korea; 2. POSCO Technical Research Laboratories, Pohang, South Korea*

**TUESDAY
MORNING
9:00**

POLIVALENTE

Session CM MAGNETIC MICRO- AND NANOSTRUCTURES (POSTER SESSION)

Tom Thomson, Chair

CM-01. Nonlinear eigenmodes of monodomain magnetic squares. (Invited) V.E. Demidov¹, U. Hansen¹, S.O. Demokritov¹ and M. Kostylev². *1. Institute for Applied Physics, University of Muenster, Muenster, Germany; 2. School of Physics, University of Western Australia, Crawley, WA, Australia*

CM-02. Synthesis and Magnetic Properties of Au Doped CoPt Nanowires. J. Min¹, J. Wu², J. Lee¹, J. Ju³ and Y. Kim¹. *1. Department of Materials Science and Engineering, Korea University, Seoul, South Korea; 2. Institute for Nano Science, Korea University, Seoul, South Korea; 3. Cooperative Center for Research Facilities, Sungkyunkwan University, Suwon, South Korea*

CM-03. FMR studies of interactions effects in magnetic nanowires arrays. O.C. Trusca^{1,2}, D. Cimpoeu¹, A. Diaconu⁴, I. Dumitru⁴, J. Lim^{1,3}, X. Zhang^{1,3}, J.B. Wiley^{1,3}, A. Stancu⁴ and L. Spinu^{1,2}. *1. Advanced Materials Research Institute, University of New Orleans, New Orleans, LA; 2. Department of Physics, University of New Orleans, New Orleans, LA; 3. Department of Chemistry, University of New Orleans, New Orleans, LA; 4. Faculty of Physics, "Alexandru Ioan Cuza" University, Iasi, Romania*

CM-04. Thermal coercivity mechanism in Fe nanoribbons and stripes. F. Garcia-Sanchez¹ and O. Chubykalo-Fesenko¹. *1. POMT, Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain*

CM-05. Patterning of magnetic films by focused ion beam irradiation. S. Tibus¹, D. Makarov², C.T. Rettner³, T. Thomson⁴, B.D. Terris⁴, T. Schrefl⁵ and M. Albrecht¹. *1. Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany; 2. Department of Physics, University of Konstanz, Konstanz, Germany; 3. IBM Almaden Research Center, San Jose, CA; 4. San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA; 5. Department of Engineering Materials, University of Sheffield, Sheffield, United Kingdom*

CM-06. A novel bottom-up fabrication process for controllable sub-100nm magnetic multilayer devices. M. Kao¹, J. Ou¹ and J. Wu¹. *1. Physics, National Changhua University of Education, Changhua, Taiwan*

CM-07. Self-organised hexagonal patterns of independent magnetic nanodots. T. Bobek¹, N. Mikuszeit², J. Camarero², S. Kyrsta³, L. Yang¹, M. Niño², C. Hofer⁴, L. Gridneva⁵, A. Persson⁵, D. Arvanitis⁵, R. Miranda^{2,6}, J.J. de Miguel², C. Teichert⁴ and H. Kurz¹. *1. Institute of Semiconductor Electronics, RWTH-Aachen, Aachen, Germany; 2. Dept. Fisica de la Materia Condensada, C-3, Univ. Autonoma de Madrid, Madrid, Spain; 3. Materials Chemistry, RWTH-Aachen, Aachen, Germany; 4. Institut für Physik, Montanuniversität Leoben, Leoben, Austria; 5. Department of Physics, Uppsala University, Uppsala, Sweden; 6. IMDEA-Nano, Madrid Institute of Advanced Studies in Nanotechnology, Madrid, Spain*

CM-08. Transverse Rectifier Based on Hybrid Magnetic/Superconducting Nanodevices. D. Perez de Lara¹, E.M. Gonzalez¹, J.V. Anguita² and J.L. Vicent¹. *1. Fisica de Materiales, Universidad Complutense de Madrid, Madrid, Spain; 2. Instituto Microelectronica, Madrid, CSIC, Tres Cantos, Madrid, Spain*

CM-09. Electrical transport study of patterned lateral Niobium-Permalloy junctions. S.R. Bakaul^{1,2}, K. Li³, G. Han² and Y. Wu¹. *1. Electrical and Computer Engineering, National University of Singapore, Singapore, Singapore; 2. Spintronic, Media and Interface, Data Storage Institute, Singapore, Singapore; 3. Industrial Materials Institute, Boucherville, QC, Canada*

CM-10. Finite size effects in [Co(1nm)/Bi(2.5nm)]_n line-structures. C. Christides¹ and T. Speliotis². *1. Department of Engineering Sciences, University of Patras, Patras, 26504, Greece; 2. Institute of Materials Science, NCSR Demokritos, Athens, 153 10, Greece*

**TUESDAY
MORNING
9:00**

Session CN MICROMAGNETICS I (POSTER SESSION)

Gino Hrkac, Chair

CN-01. Dynamic and temperature effects in spin-transfer switching. H. Pham^{1,2}, D. Cimpoeu^{1,3}, A. Stancu³ and L. Spinu^{1,2}. *1. Advanced Materials Research Institute, University of New Orleans, New Orleans, LA; 2. Department of Physics, University of New Orleans, New Orleans, LA; 3. Department of Physics, "Al. I. Cuza" University, Iasi, Romania*

CN-02. Analysis of spin transfer switching speed in magnetic nano-structures. J. Guo¹, T. Seng Ghee², J. Mansoor Bin Abdul¹ and L. Lin¹. *1. National University of Singapore, Singapore, Singapore; 2. Data Storage Institute, Singapore, Singapore*

CN-03. Current induced domain wall motion in ferromagnetic wires with out-of-plane magnetization. *H. Szambolics^{1,3}, J. Toussaint^{1,3}, A. Marty⁴, I. Miron² and L. Buda-Prejbeanu^{2,3}* *1. Department of Nanosciences, Institut Neel, CNRS, Grenoble, France; 2. Laboratoire SPINTEC, CEA-CNRS, Grenoble, France; 3. Institut National Polytechnique de Grenoble, Grenoble, France; 4. Laboratoire SP2M, CEA-CNRS, Grenoble, France*

CN-04. Fast magnetization switching with short pulses. *W. Scholz¹, T.M. Crawford², T.W. Clinton¹, T. Ambrose¹, S. Kaka¹ and S. Batra¹* *1. Research, Seagate, Pittsburgh, PA; 2. USC NanoCenter, Univ. of South Carolina, Columbia, SC*

CN-05. Micromagnetic Simulations of Domain Wall Depinning Forced by Oscillating Fields. *O. Alejos Ducal¹, E. Martínez Vecino², L. López Díaz³ and L. Torres Rincón³* *1. Electricidad y Electrónica, Universidad de Valladolid, Valladolid, Valladolid, Spain; 2. Ingeniería Electromecánica, Universidad de Burgos, Burgos, Burgos, Spain; 3. Física Aplicada, Universidad de Salamanca, Salamanca, Salamanca, Spain*

CN-06. Effects of Shape Anisotropy on the Walker Breakdown Field in Field-Driven Domain Wall Motion. *W. Kim¹, S. Jung², H. Lee² and K. Lee¹* *1. Korea University, Seoul, South Korea; 2. POSTECH, Pohang, South Korea*

CN-07. Testing the theory of nucleation in infinite square prism—micromagnetic simulations. *K.M. Lebecki¹* *1. Institute of Physics, PAS, Warsaw, Poland*

CN-08. Finite difference and edge finite element approaches for dynamic micromagnetic modeling. *A. Manzin¹, B. Van de Wiele², O. Bottauscio¹, M. Chiampi³, L. Dupré² and F. Olyslager⁴* *1. Istituto Nazionale di Ricerca Metrologica, Torino, Italy; 2. Department of Electrical Energy, Systems and Automation, Ghent University, Ghent, Belgium; 3. Department of Electrical Engineering, Politecnico di Torino, Torino, Italy; 4. Department of Information Technology, Ghent University, Ghent, Belgium*

CN-09. Computation of magnetization normal oscillations and resonant frequencies for ferromagnetic nanoparticles. *M. d'Aquino¹, C. Serpico², G. Miano² and G. Bertotti³* *1. Dipartimento per le Tecnologie, Università di Napoli "Parthenope", Napoli, Italy; 2. Dipartimento di Ingegneria Elettrica, Università di Napoli "Federico II", Napoli, Italy; 3. Istituto Nazionale di Ricerca Metrologica (INRiM), Torino, Italy*

CN-10. Micromagnetic modeling of magnetization switching mechanisms in high magnetoresistance tunnel junctions. *L. Torres¹, G. Finocchio², M. Carpentieri², E. Martinez³, E. Jaromirska¹, O. Alejos⁴ and L. Lopez-Diaz¹* *1. Dept. Fisica Aplicada, Universidad de Salamanca, Salamanca, Spain; 2. University of Messina, Messina, Messina, Italy; 3. Universidad de Burgos, Burgos, Burgos, Spain; 4. Universidad de Valladolid, Valladolid, Valladolid, Spain*

CN-11. Effect of Sawtooth Shape on Switching Process of Write Head. *S. Wang¹, D. Wei¹ and K. Gao²* *1. Dept. of Materials Science and Engineering, Tsinghua University, Beijing, China; 2. Seagate Technology Seagate Technology, Bloomington, MN*

CN-12. Micromagnetic study of read sensitivity: Influence of curved hard bias and granular media. *L. Wang¹, G.C. Han¹, S.G. Wu¹ and B. Liu¹* *1. Spintronics, Media and Interface, Data Storage Institute, Singapore, Singapore*

Session C0
NANOSTRUCTURED HARD MAGNETIC MATERIALS - I
(POSTER SESSION)
Thomas Schrefl, Chair

CO-01. Remanence analysis of nanocrystalline, epitaxial SmCo₅ films in high pulsed fields up to 35 T. *V. Neu¹, J. Freudenberger¹, A. Singh¹ and L. Schultz¹* *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany*

CO-02. Effect of Ga addition on the magnetic properties of Nd₆₀Fe₃₀Al_{10-x}Ga_x alloy. *W. Kaszuwara¹, B. Michalski¹, M. Leonowicz¹ and J. Latuch¹* *1. Faculty of Materials Science and Engineering, Warsaw University of Technology, Warsaw, Poland*

CO-03. Ab initio calculation of the magnetic structures in Nd₂Fe₁₄B/ α -Fe nanocomposite materials. *Y. Toga¹, H. Tsuchiura¹ and A. Sakuma¹* *1. Applied Physics, Tohoku University, Sendai, Japan*

CO-04. Nanostructure and Magnetic Properties of Nd-Fe-B Thin Film Fabricated by UHV Sputtering. *D. Ogawa¹, T. Akiya², M. Oogane¹, H. Kato^{2,3} and Y. Ando¹* *1. Department of Applied Physics, Tohoku University, Sendai, Japan; 2. New Industry Creation Hatchery Center (NICHe), Tohoku University, Sendai, Japan; 3. Department of Applied Mathematics and Physics, Yamagata University, Yonezawa, Japan*

CO-05. Effect of Nd and Nd₂O₃ layers on the magnetic properties for Nd-Fe-B thin films. *N. Oka¹, T. Sato², H. Kato¹ and T. Shima¹* *1. Faculty of Engineering, Tohoku Gakuin University, Tagajo, Japan; 2. Toyota Central R&D Labs., Nagakute, Japan*

CO-06. Refinement of surface morphology of Nd-Fe-B thin film by low temperature deposition. *H. Kato¹, I. Honda¹, T. Sato² and T. Shima¹* *1. Faculty of Engineering, Tohoku Gakuin University, Tagajo, Japan; 2. Toyota Central R&D Labs., Nagakute, Japan*

CO-07. Enhancement of coercivity for Nd-Fe-B thin films with Tb and Dy layer. *T. Sato¹, N. Oka², H. Kato² and T. Shima²* *1. Toyota Central R&D Labs., Inc., Aichi, Japan; 2. Faculty of Engineering, Tohoku Gakuin University, Tagajyo, Japan*

CO-08. FePt-based nanocomposite ribbons as exchange coupled magnets. *A. Crisan^{1,2}, O. Crisan¹, N. Randrianantoandro² and I. Skorvanek³* *1. National Institute for Materials Physics, Bucharest-Magurele, Romania; 2. Laboratoire de Physique de l'Etat Condense, Université du Maine, Le Mans, France; 3. Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovakia*

Session CP
HYSTERESIS MODELLING I
(POSTER SESSION)

A. Petru, Chair

- CP-01. Genetic algorithm for Jiles-Atherton parameters optimization.** *F.A. Cuéllar¹ and A. Mendoza²1. Physics Department, Universidad Nacional de Colombia, Bogotá, Colombia; 2. Grupo de Materiales Magnéticos y Nanoestructuras, Universidad del Quindío, Armenia, Colombia*
- CP-02. Angle Difference between B vector and H vector in Anisotropic Electrical Steel.** *K. Fujisaki^{1,2} and S. Satou³1. Technical Development Bureau, Nippon Steel Corporation, Futtsu-city, Chiba-prefecture, Japan; 2. Graduate School of Environmental Studies, Tohoku University, Sendai-city, Miyagi-prefecture, Japan; 3. N-Teck Ohita Corporation, Ohita-city, Japan*
- CP-03. Data collapse and viscosity in three-dimensional magnetic systems.** *A. Adedoyin¹ and A. Petru¹1. Electrical and Computer Engineering, Florida State University, Tallahassee, FL*
- CP-04. A Simplified Iron Loss Model for Laminated Magnetic Cores.** *E. Dlala¹1. Department of Electrical Engineering, Helsinki University of Technology, Espoo, Finland*
- CP-05. Modeling of Vector Hysteresis of Soft Magnetic Composite Material.** *Y. Guo¹, H. Lu², J. Zhu¹, Z. Lin¹, J. Zhong¹ and S. Wang³1. Faculty of Engineering, University of Technology Sydney, Sydney, NSW, Australia; 2. Faculty of Information Technology, University of Technology Sydney, Sydney, NSW, Australia; 3. Faculty of Electrical Engineering, Xi'an Jiaotong University, Xi'an, Shaanxi, China*
- CP-06. Analysis of the local material degradation near cutting edges of electrical steel sheets.** *G. Crevecoeur¹, P. Sergeant¹, L. Dupre¹, L. Vandenbossche¹ and R. Van de Walle²1. Departement of Electrical Energy, Systems and Automation, Ghent University, Ghent, Belgium; 2. Department of Electronics and Information systems, Ghent University, Ghent, Belgium*
- CP-07. Modelling of magnetostrictive material and linear controlling of nonlinear magnetostrictive drive system based on SVM.** *J. An¹, Q. Yang¹, Z. Ma¹, H. Chen¹, L. Hou¹, W. Yang¹ and F. Liu¹1. hebei university of technology, Tianjin, China*
- CP-08. Modelling hysteresis of a first order magneto-structural phase transformation.** *V. Basso¹, M. Lo Bue², C.P. Sasso¹ and M. Küpferling¹1. INRIM, Torino, Italy; 2. SATIE, ENS Cachan, CNRS, UniverSud, Cachan, France*
- CP-09. The Preisach distribution and the symmetry of the local hysterons in strongly interacting nanoparticle systems.** *R. Tanasa¹ and A. Stancu¹1. Department of Physics, "Alexandru Ioan Cuza" University, Iasi, Romania*

Session CQ
SOFT MAGNETIC MATERIALS AND APPLICATIONS I
(POSTER SESSION)

Andy Knight, Chair

- CQ-01. Magnetic and magneto-thermal properties of RFe₄Ge₂(R=Er,Dy) compounds.** *P. Kumar¹, N.K. Singh¹, K.G. Suresh¹ and A.K. Nigam²1. Physics, IIT Bombay, Mumbai, Maharastra, India; 2. Tata Institute of Fundamental Research, Tata Institute of Fundamental Research, Mumbai, Maharastra, India*
- CQ-02. Capacity of magnetic inductive parameters on annealing characterization of cold rolled low carbon steel.** *K. Gurruchaga^{1,2}, A. Martínez-de-Guerenu¹, M. Soto^{1,2} and F. Arizti^{1,2}1. CEIT, San Sebastian, Spain; 2. Tecnun, San Sebastian, Spain*
- CQ-03. A fully digital magnetic property measurement system.** *M. Soto^{1,2}, A. Martínez-de-Guerenu¹, K. Gurruchaga^{1,2} and F. Arizti^{1,2}1. CEIT, San Sebastian, Spain; 2. Tecnun (University of Navarra), San Sebastian, Spain*
- CQ-04. Preparation and magnetorheology of solvent-cast magnetite nanoparticle and poly(vinyl butyral) composite.** *B. Park¹, J. You¹, F. Fang¹ and H. Choi¹1. Department of Polymer Science and Engineering, Inha University, Incheon, South Korea*
- CQ-05. 3D Magnetic Field Analysis by Homogenization Method for Thin Steel Plate of Magnetic Field.** *K. Fujisaki^{1,2}, M. Fujikura¹, J. Mino³ and S. Satou⁴1. Technical Development Bureau, Nippon Steel Corporation, Futtsu-city, Chiba-prefecture, Japan; 2. Graduate School of Environmental Studies, Tohoku University, Sendai-city, Japan; 3. Nippon Steel Engineering Corporation, Tokyo, Japan; 4. N-Teck Ohita Corporation, Ohita, Japan*
- CQ-06. Field Coil for Magneto-Optic Switching : Capacitance Considerations.** *J. Tioh¹, M. Mina¹ and R. Weber¹1. Electrical and Computer Engineering, Iowa State University, Ames, IA*
- CQ-07. Power loss measurement and prediction of soft magnetic powder composites magnetised under non-sinusoidal excitation.** *P. Marketo¹, J.P. Hall¹ and S.E. Zirka²1. School of Engineering, Cardiff University, Cardiff, Wales, UK, United Kingdom; 2. Department of Applied Physics and Technology, Dnepropetrovsk National University, Dnepropetrovsk, Ukraine*
- CQ-08. Electromagnetic Wave Absorption Characteristics of Powder-Type Magnetic Wood Considering the Mixing Ratios of Two Types of Magnetic Powder.** *H. Oka¹, Y. Yanagidate¹, H. Osada¹, K. Kubota¹, Y. Namizaki² and F.P. Dawson³1. Iwate University, Morioka, Japan; 2. Iwate Industrial Research Institute, Morioka, Japan; 3. University of Toronto, Toronto, ON, Canada*
- CQ-09. Influence of asymmetry in stator geometry and magnetic circuit on cogging torque in PM brushless machines.** *Z. Zhu¹, J. Chen¹, L. Wu¹ and D. Howe¹1. University of Sheffield, Sheffield, United Kingdom*

CQ-10. Electromagnetic modeling of a novel linear oscillating actuator. Z. Zhu¹, X. Chen¹, D. Howe¹ and S. Iwasaki². *1. University of Sheffield, Sheffield, United Kingdom; 2. IMRA UK Research Center, Brighton, United Kingdom*

CQ-11. Non-oriented electrical steel and magnetostriction: a review. A.M. Severino¹. *1. Departamento de Física - CCNE, Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil*

CQ-12. Optimization of Design Parameters for Ferrite Inductor for 10 MHz On-chip Power Module. S. Bae^{1,2}, Y. Hong^{1,2}, J. Lee^{1,2}, J. Jalli^{1,2}, G.S. Abo^{1,2}, A. Lyle^{1,2}, H. Han^{1,2} and G.W. Donohoe³. *1. Department of Electrical and Computer Engineering, University of Alabama, Tuscaloosa, AL; 2. MINT Center, University of Alabama, Tuscaloosa, AL; 3. Department of Electrical and Computer Engineering, University of Idaho, Moscow, ID*

Session CR MAGNETIC NANOCLOUDS AND NANOPARTICLES II (POSTER SESSION)

Patricia de la Presa, Chair

CR-01. Magnetic properties of cobalt ferrite nanoparticles obtained by non-aqueous synthesis. C. Vázquez-Vázquez¹, C. Mateo-Mateo¹, M. Buján-Núñez¹, M. López-Quintela¹, D. Serantes², D. Baldomir² and J. Rivas². *1. Facultad de Química. Departamento de Química Física, Universidad de Santiago de Compostela, Santiago de Compostela, A Coruña, Spain; 2. Facultad de Física. Departamento de Física Aplicada, Universidad de Santiago de Compostela, Santiago de Compostela, A Coruña, Spain*

CR-02. Magnetic Properties of Nano-composite Particles of FePt/FeRh. Y. Hnin¹, S. Inoue¹, N.T. Nam¹, T. Suzuki¹ and Y. Hirotsu². *1. Information Storage Materials Laboratory, Toyota Technological Institute, Nagoya, Japan; 2. The Institute of Scientific and Industrial Research, Osaka University, Osaka, Japan*

CR-03. Synergic application of albumin nanoparticles: combination of Photodynamic Therapy with Cellular Hyperthermia. M.M. Andrade Rodrigues¹, A.R. Simioni¹, F.L. Primo^{2,1}, M.P. Siqueira-Moura², Z.G. Lacava³, P.C. Morais⁴ and A.C. Tedesco¹. *1. Departamento de Química, Grupo de Fotobiologia e Fotomedicina, Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Universidade de São Paulo, 14040-901, Brazil, Ribeirão Preto, SP, Brazil; 2. Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Universidade de São Paulo, Ribeirão Preto-SP, 14040-903, Brazil, Ribeirão Preto, SP, Brazil; 3. Universidade de Brasília, Instituto de Ciências Biológicas, Brasília DF 70910-900, Brazil, Ribeirão Preto, DF, Brazil; 4. Universidade de Brasília, Instituto de Física, Núcleo de Física Aplicada, Brasília DF 70910-900, Brazil, Ribeirão Preto, DF, Brazil*

CR-04. Synthesis of Ni nanoparticles by dc magnetron sputtering. H. Cui¹, M. Sanz¹, M. Maicas¹ and C. Aroca¹. *1. ISOM, Universidad Politécnica de Madrid, Madrid, Madrid, Spain*

CR-05. Influence of the Si substrate on the transport and magnetotransport properties of nanostructured FeAg thin films. J. Alonso¹, M. Fdez-Gubieda¹, J. Barandiarán¹, J. Chaboy³, L. Fernández Barquín⁴, I. Orue², A. Svalov¹ and N. Kawamura⁵. *1. Electricidad y Electrónica, Universidad del País Vasco, Bilbao, Spain; 2. SGIKER, Servicios Generales de medidas magnéticas, Universidad del País Vasco, Bilbao, Spain; 3. Instituto de Ciencia de Materiales de Aragón, CSIC-Universidad de Zaragoza, Zaragoza, Spain; 4. CITIMAC, Universidad de Cantabria, Santander, Spain; 5. Japan Synchrotron Radiation Research Institute, Kouto, Japan*

CR-06. WITHDRAWN

CR-07. Characterization of nanocrystalline iron oxide powder modified by electroless nickel plating. C. Lin¹, C. Tsay¹, T. Yang¹, R. Yang², D. Hung³ and Y. Yao³. *1. Materials Science and Engineering, Feng Chia University, Taichung, Taiwan; 2. Dept. of Aerospace and Systems Engineering, Feng Chia Univ, Taichung, Taiwan; 3. Institute of Physics, Academia Sinica, Taipei, Taiwan*

CR-08. Functionalized silica coated maghemite nanoparticles prepared by the microemulsion method for biomedical applications. A. Drmota¹, A. Košak² and A. Znidaršič^{1,2}. *1. Kolektor Nanotesla Institute, Ljubljana, Slovenia; 2. Kolektor Magma d.o.o., Ljubljana, Slovenia*

CR-09. Magnetic nanoparticles obtained by ultrahigh vacuum glancing angle deposition technique at high temperature. X. Bendaña¹, E. Ferreira¹, G. Armelles¹, A. Cebollada¹ and J. Garcia Martin¹. *1. Instituto de Microelectrónica de Madrid IMM-CNM-CSIC, Tres Cantos, Madrid, Spain*

CR-10. Magnetic properties of nanocrystalline Co thin films grown on glass. B. Presa¹, R. Matarranz¹, M.C. Contreras¹, J.F. Calleja¹, L.E. Fernandez-Outon² and K. O'Grady². *1. Departamento de Física, Universidad de Oviedo, Oviedo, Principado de Asturias, Spain; 2. Department of Physics, The University of York, York, United Kingdom*

CR-11. Core-shell magnetic behaviour of iron ultrathin films prepared by sputtering at very low temperatures. F. Jiménez-Villacorta¹, R.M. Morillas¹, E. Salas¹, E. Céspedes¹ and C. Prieto¹. *1. Instituto de Ciencia de Materiales de Madrid - CSIC, Madrid, Spain*

CR-12. Preparation and magnetic properties of disordered CdFe₂O₄ thin films. H. Akamatsu¹, Y. Zong¹, Y. Fujiki¹, K. Kamiya¹, K. Fujita¹, S. Murai¹ and K. Tanaka¹. *1. Material Chemistry, Kyoto University, Kyoto, Japan*

CR-13. Controlled synthetic conditions of FePt nanoparticles with high magnetization for biomedical applications. D. Wei^{1,4}, D. Hung², C. Ho³, P. Chen³ and Y. Yao⁴. *1. Institute of Physics, Academia Sinica, Taipei, Taiwan; 2. Department of Information and Telecommunications Engineering, Ming Chuan University, Taipei, Taiwan; 3. Department of Chemical Engineering, Tunghai University, Taichung, Taiwan; 4. Department of Materials Engineering, Tatung University, Taipei, Taiwan*

CR-14. Properties of Co-HfO₂ nanogranular magnetic thin films. M. Chadha¹ and V. Ng¹. *1. ECE, National University of Singapore, Singapore, Singapore*

CR-15. Fe₃O₄ incorporated AOT-Alginate - composite nanoparticles for drug delivery. C. Sudakar¹, A. Dixit¹, R. Regmi¹, R. Naik², G. Lawes¹, V.M. Naik², P.P. Vaishnav³, U. Toti⁴ and J. Panyam⁴. *1. Department of Physics and Astronomy, Wayne State University, Detroit, MI; 2. Department of Natural Sciences, University of Michigan-Dearborn, Dearborn, MI; 3. Department of Physics, Kettering University, Flint, MI; 4. College of Pharmacy, University of Minnesota, Minneapolis, MN*

CR-16. Iron Oxide Nanoparticles Embedded in Thermoplastic Polymers for Magneto-optical Devices. G. Carotenuto², D. Davino¹, A. Longo², V. Pagliarulo¹, G. Pepe³ and C. Visone¹. *1. Engineering Department, University of Sannio, Benevento, Italy; 2. Istituto per i materiali compositi, CNR, Napoli, Italy; 3. Coherencia INFM - Physics Department, Università di Napoli Federico II, Napoli, Italy*

CR-17. Novel single-step synthesis of Fe1-xCox and MgO based core-shell structured nanospheres: High magnetization particles for biomedicine, catalysis and spintronics applications. C. Martinez-Boubeta¹, L. Balcells¹, F. Sandiumenge¹, L. Casas³, A. Calleja¹, V. Laukhin^{1,2}, C. Monty⁴ and B. Martínez¹. *1. ICMA, Bellaterra, Barcelona, Spain; 2. Institut Català de Recerca i Estudis Avançats (ICREA), Passeig Lluís Companys 23, Barcelona, Spain; 3. Unitat de Cristal·lografia i Mineralogia, Dept. Geologia-UAB, Bellaterra, Barcelona, Spain; 4. CNRS/Procédés, Matériaux et Energie Solaire (PROMES), Font Romeu, France*

**TUESDAY
MORNING
9:00**

POLIVALENTE

Session CS PERPENDICULAR GRANULAR MEDIA (POSTER SESSION)

Simon Greaves, Chair

CS-01. High Perpendicular Anisotropy Layers stacked Exchange Coupled Composite Media. S. Oikawa¹, T. Maeda¹ and A. Takeo¹. *1. Hard Disk Drive Development Dept., TOSHIBA Corporation, Kawasaki, Japan*

CS-02. Segregation Mechanisms in Co-based Oxide Recording Media. E.E. Marinero¹, D.T. Margulies¹, B.R. York¹ and P. Rice². *1. Hitachi San Jose Research Center, San Jose, CA; 2. IBM Almaden Research Center, San Jose, CA*

CS-03. Pseudo-hcp material and its evaluation for perpendicular recording media. S. Saito¹ and M. Takahashi^{2,1}. *1. Electronic engineering, Tohoku university, Sendai, Miyagi, Japan; 2. New industry creation hatchery center, Tohoku univ., Sendai, Miyagi, Japan*

CS-04. Magnetic interaction between recording layer and soft underlayer in granular-type perpendicular magnetic recording media with thin intermediate layer. K. Shintaku¹. *1. Akita Research Institute of Advanced Technology, Akita Prefectural R&D Center, Akita, Japan*

CS-05. A new method for controlling an exchange coupling of perpendicular recording media. J. Ariake¹ and N. Honda¹. *1. AIT, Akita Prefectural R&D Center, Akita, Japan*

CS-06. A study of perpendicular magnetic recording media with an exchange control layer. K. Tang¹, K. Takano¹, G. Choe¹, G. Wang¹, J. Zhang¹, X. Bian¹ and M. Mirzamaani¹. *1. Hitachi Global Storage Technologies, San Jose, CA*

CS-07. Al-N; a hexagonal-nitride seed layer underlayered Ru in granular-type perpendicular media. S. Ishibashi¹, S. Saito¹, A. Hashimoto¹ and M. Takahashi^{2,1}. *1. Dept. of Electronics Engineering, Tohoku University, Sendai, Japan; 2. New Industry Creation Hatchery Center, Tohoku University, Sendai, Japan*

CS-08. Granular perpendicular soft layer with tunable anisotropy energy in exchange coupled composite media. H. Hou¹, M. Lin¹, R. Liao¹, C. Lai¹, R. Chen² and C. Lee². *1. Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan; 2. China Steel Corporation, Kaohsiung, Taiwan*

CS-09. Effect of deposition condition of Ru-oxide/Ru bilayers on magnetic properties and orientation of CoPtCr-SiO₂ perpendicular recording media. T. Matsui¹, A. Hashimoto¹, K. Hirata¹, H. Fujiura¹, S. Matsunuma², T. Inoue², T. Doi² and S. Nakagawa¹. *1. Dept. of Physical Electronics, Tokyo Institute of Technology, Tokyo, Japan; 2. Hitachi Maxell, Ibaraki, Japan*

CS-10. Remanence measurements of perpendicular recording media. T. Deakin¹, C. Bunce¹, K. O'Grady¹ and S.Z. Wu². *1. Department of Physics, The University of York, York, United Kingdom; 2. Seagate Media Research, Fremont, CA*

CS-11. Microwave-assisted magnetization reversal in exchange spring media. M.A. Bashir¹, J. Dean¹, T. Schrefl¹, A. Goncharov¹, G. Hrkac¹, S. Bance¹, D.A. Allwood¹ and D. Suess². *1. Engineering Materials, University Of Sheffield, Sheffield, United Kingdom; 2. Solid State Physics, Vienna University of Technology, Vienna, Austria*

CS-12. Micromagnetic Simulations of Cluster-pinned Recording Media. C. Loke¹, S. Greaves¹ and H. Muraoka¹. *1. RIEC, Tohoku University, Sendai, Miyagi, Japan*

CS-13. Effects of exchange and dipolar interactions on the determination of intrinsic switching field distributions in perpendicular recording media. Y. Liu¹, K.A. Dahmen¹, O. Hovorka² and A. Berger². *1. Department of Physics, University of Illinois at Urbana-Champaign, Urbana, IL; 2. CIC nanoGUNE Consolider, Donostia - San Sebastián, Spain*

CS-14. Hybrid Soft Underlayer for Perpendicular Recording Media. Y. Dong¹ and R. Victora¹. *1. Department of Electrical and Computer Engineering, The Center for Micromagnetics and Information Technologies (MINT), University of Minnesota, Minneapolis, MN*

CS-15. Fast precessional switching in exchange spring media. D. Suess¹, J. Fidler¹, J. Dean² and T. Schrefl². *1. Institut of Solid State Physics, Technical University of Vienna, Vienna, Austria; 2. Department of Engineering Materials, The University of Sheffield, Sheffield, UK., Sheffield, United Kingdom*

TUESDAY
MORNING
9:00

POLIVALENTE

Session CT
PERPENDICULAR HIGH KU MEDIA
(POSTER SESSION)

Mohammad Mirzamaani, Chair

- CT-01. Co-rich Co-Pt films with low ordering temperature and high perpendicular hard magnetic properties for high-density magnetic recording media.** *S. Chen^{1,2}, P. Kuo³, C. Shen³, Y. Fang³ and S. Hsu³* *1. Department of Materials Engineering, MingChi University of Technology, Taipei, Taiwan; 2. Center for Nanostorage Research, National Taiwan University, Taipei, Taiwan; 3. Institute of Materials Science and Engineering, National Taiwan University, Taipei, Taiwan*
- CT-02. Microstructure and magnetic properties of FePt films on anodized aluminum oxide membranes.** *C. Yu¹, S. Chen², Y. Yao³ and J. Wu²* *1. Department of Applied Physics, National University of Kaohsiung, Kaohsiung, Taiwan; 2. Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan; 3. Department of Materials Engineering, Tatung University, Taipei, Taiwan*
- CT-03. Effect of MgO addition on structural and magnetic properties of (001) textured FePt thin films.** *A. Sun^{1,2}, Y. Tsai³, F. Yuan⁴, J. Hsu^{1,2} and P. Kuo³* *1. Physics, National Taiwan University, Taipei, Taiwan; 2. Center for Nanostorage Research, National Taiwan University, Taipei, Taiwan; 3. Materials Science and Engineering, National Taiwan University, Taipei, Taiwan; 4. Physics, Academia Sinica, Taipei, Taiwan*
- CT-04. Thickness Dependence on (001) Texture Evolution and Magnetic Properties of Sputter-Deposited FePt:MgO Nanocomposite Films.** *H. Kim¹, K. Kim¹, S. Lee¹ and W. Jeung²* *1. Materials Science and Engineering, Korea University, Seoul, South Korea; 2. Korea Institute of Science and Technology, P.O.Box 131, Seoul, South Korea*
- CT-05. Dependence of ordering kinetics of FePt thin films on substrates.** *C. Zha^{1,2}, S. He¹, B. Ma¹, Z. Zhang¹, F. Gan¹ and Q. Jin¹* *1. Department of Optical Science and Engineering, Fudan University, Shanghai, China; 2. Department of Microelectronics and Applied Physics, Royal Institute of Technology, Stockholm, Sweden*
- CT-06. Domain reversal behavior of ultrathin FePt:C films.** *H. Ko¹, P. Alagarsamy¹, S. Shin¹, W. Byun² and S. Kim²* *1. Physics, KAIST, Daejeon, South Korea; 2. Material Science, KAIST, Daejeon, South Korea*
- CT-07. Fabrication of easy-axis-aligned ultrahigh-density FePt nanoparticles.** *Y. Wu¹, L. Wang¹ and C. Lai¹* *1. Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan*
- CT-08. Structural and magnetic properties of textured Fe/FePt bilayer.** *S.H. He¹, B. Ma¹, C.L. Zha¹, Z.Z. Zhang¹ and Q.Y. Jin¹* *1. Department of Optical Science and Engineering, Fudan University, Shanghai, Shanghai, China*

CT-09. Control of Curie temperature of FePt(Cu) films prepared from Pt(Cu)/Fe bilayers. *J. Ikemoto¹, Y. Imai¹ and S. Nakagawa¹* *1. Dept. of Physical Electronics, Tokyo Institute of Technology, Tokyo, Japan*

CT-10. Exchange Coupling Assisted FePtC Perpendicular Recording Media. *J. Hu¹, J. Chen², Y. Ding¹, B. Lim¹, W. Phyoe¹ and B. Liu¹* *1. Data Storage Institute, Singapore, Singapore; 2. Department of Materials Science and Engineering, National University of Singapore, Singapore, Singapore*

CT-11. Epitaxial thin SmCo₅ films with perpendicular anisotropy. *M. Seifert¹, V. Neu¹ and L. Schultz¹* *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany*

CT-12. Studies on Sm(Co,Cu)₅ thin films with perpendicular anisotropy for extremely high areal density recording. *X. Liu¹, H. Zhao¹, Y. Kubota² and J. Wang¹* *1. The Center for Micromagnetics and Information Technologies, Department of Electrical and Computer Engineering, University of Minnesota, Minneapolis, MN; 2. Seagate Research, Pittsburgh, PA*

CT-13. Second order anisotropy in exchange spring systems. *B.F. Valcu¹, A. Dobin¹ and E. Girtl¹* *1. Seagate Technology, Fremont, CA*

TUESDAY
MORNING
9:00

Session CU
BIT PATTERNED MEDIA I
(POSTER SESSION)

Branson Belle, Chair

- CU-01. Magnetic recording in patterned media at 5 - 10 Tbit/in²** *S. Greaves¹, Y. Kanai² and H. Muraoka¹* *1. RIEC, Tohoku University, Sendai, Japan; 2. IEE, Niigata Institute of Technology, Kashiwazaki, Japan*
- CU-02. Characterisation of a 2 Tbit/in² patterned media recording system.** *N. Degawa¹, S.J. Greaves¹, H. Muraoka¹ and Y. Kanai²* *1. RIEC, Tohoku University, Sendai, Miyagi, Japan; 2. IEE, Niigata Institute of Technology, Niigata, Niigata, Japan*
- CU-03. Simulation Study of High Density Bit Patterned Media with Inclined Anisotropy.** *N. Honda¹, K. Yamakawa¹ and K. Ouchi¹* *1. Research Institute of Advanced Technology, Akita Prefectural R & D Center, Akita-shi, Japan*
- CU-04. Writability in Discrete Track Media.** *K. Moon¹, C. Che¹, Y. Tang², M.T. Moneck², J. Zhu² and N. Takahashi³* *1. Samsung Information Systems America, San Jose, CA; 2. ECE Department, Carnegie Mellon University, Pittsburgh, PA; 3. Fuji Electric Advanced Technology, Nagano, Japan*

CU-05. Magnetization switching experiments on sub-micron Co/Pt multilayer dot with pulse field generator with nanoseconds duration. *N. Kikuchi¹, I. Atsuo¹, S. Okamoto¹ and O. Kitakami¹. IMRAM Tohoku University, Sendai, Japan*

CU-06. Dot size dependence of magnetic properties in CoPt dot arrays fabricated using diblock copolymer. *K. Kimura¹, Y. Kamata¹, T. Maeda¹, Y. Isowaki¹ and A. Kikitsu¹. Storage Materials & Devices Laboratory, Corporate Research & Development Center, Toshiba Corporation, Kawasaki, Kanagawa, Japan*

CU-07. Study on ferro-antiferromagnetic transition in L1₀ FePtRh film for bit patterning. *T. Hasegawa¹, J. Miyahara¹, Y. Fu², T. Wang², H. Saito¹ and S. Ishio¹. Materials Science and Engineering, Akita University, Akita, Japan; 2. Venture Business Laboratory, Akita University, Akita, Japan*

CU-08. CoCrPt-SiO₂ films on spherical SiO₂ particle arrays. *C. Brombacher¹, F. Springer², H. Rohrmann⁴, M. Kratzer⁴, M. Parlinska³, S. Meier³, P. Kappenberger³ and M. Albrecht¹. Institute of Physics, Chemnitz University of Technology, D-09107 Chemnitz, Germany; 2. Department of Physics, University of Konstanz, D-78457 Konstanz, Germany; 3. Nanoscale Materials Science, Empa, CH-8600 Dübendorf, Switzerland; 4. Data Storage, OC Oerlikon Balzers AG, FL-9496 Balzers, Liechtenstein*

CU-09. Fabrication of nanomagnet arrays by exfoliating thin films sputter-deposited onto molds. *H. Oshima^{1,2}, H. Kikuchi^{1,2}, H. Nakao^{1,2}, K. Itoh^{1,2}, T. Morikawa³, H. Tamura⁴, K. Nishio^{5,6} and H. Masuda^{5,6}. Fujitsu Laboratories Ltd., Atsugi 243-0197, Japan; 2. Yamagata Fujitsu Ltd., Higashine 999-3701, Japan; 3. Fujitsu Laboratories Ltd., Akashi 674-8555, Japan; 4. Fujitsu Ltd., Kawasaki 211-8588, Japan; 5. Kanagawa Academy of Science and Technology, Sagami-hara 229-1131, Japan; 6. Tokyo Metropolitan University, Hachioji 192-0397, Japan*

CU-10. Design of Ni-Mold for Discrete Track Media. *K. Ichikawa¹, T. Usa², K. Nishimaki² and K. Usuki¹. Recording Media Research Laboratories, FUJIFILM Corp., Odawara Kanagawa, Japan; 2. Production Engineering & Development Center, FUJIFILM Corp., Odawara Kanagawa, Japan*

CV-02. Optimal Design of Microwave Absorbers Using Ferrite-epoxy and Iron-epoxy Composites. *R. Yang¹, S. Hsu¹, C. Lin² and C. Tsay². Aerospace and Systems Engineering, Feng Chia University, Taichung, Taiwan; 2. Materials Science and Engineering, Feng Chia University, Taichung, Taiwan*

CV-03. Strong Magnetoelectric Coupling at Microwave Frequencies in Metallic Magnetic Film / PZT Composites. *C.I. Pettiford¹, J. Lou¹, L. Russell¹ and N.X. Sun¹. Northeastern University, Boston, MA*

CV-04. Nonlinear electrical tuning of ferromagnetic resonance in YIG film - PZT layered structures. *Y. Fetisov¹ and G. Srinivasan². Moscow State Institute of Radio Engineering, Electronics and Automation, Moscow, Russian Federation; 2. Physics Department, Oakland University, Rochester, MI*

CV-05. Generation of chaotic spin waves in magnetic film active feedback rings through four-wave parametric processes. *A. Kondrashov¹, A. Ustinov¹, T. Stemler², B. Kalinikos^{1,3}, M. Wu³ and H. Benner². Physical Electronics and Technology, St.Petersburg Electrotechnical University, St.Petersburg, Russian Federation; 2. Institute for Solid State Physics, Darmstadt University of Technology, Darmstadt, Germany; 3. Department of Physics, Colorado State University, Fort Collins, CO*

CV-06. Particle Effect of Electromagnetic Penetration in High Frequency in H Field and B Field application. *K. Fujisaki^{1,2}. Technical Development Bureau, Nippon Steel Corporation, Futtsu-city, Chiba-prefecture, Japan; 2. Graduate School of Environmental Studies, Tohoku University, Sendai, Japan*

CV-07. The X-band permittivity of iron-epoxy composites under the magnetic field. *H. Dung Shing¹, S. Hsu³, W. Liang³, C. Lin², C. Tsay², Y. Yao⁴ and R. Yang³. Department of Information and Tele. Engineering, Ming Chuan University, Taipei, Taiwan; 2. Department of Material Science and Engineering, Feng Chia University, Taichung, Taiwan; 3. Department of Aerospace and Systems Engineering, Feng Chia University, Taichung, Taiwan; 4. Department of Materials Engineering, Tatung University, Taipei, Taiwan*

CV-08. High-frequency Magnetic Properties and Attenuation Characteristics for Barium Ferrite Composites. *Z. Li¹, G. Lin¹, Y. Wu¹ and L. Kong¹. Temasek Laboratories, National University of Singapore, Singapore, Singapore*

CV-09. High frequency property of polyol-derived FeCo nanoparticles for EWA application. *D. Kodama¹, K. Shinoda², R.J. Joseyphus³, Y. Shimada⁴, K. Tohji¹ and B. Jeyadevan¹. Graduate School of Environmental Studies, Tohoku University, Sendai, Japan; 2. Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, Sendai, Japan; 3. Department of Physics, National Institute of Technology, Tiruchirappalli, India; 4. Department of Electrical and Communication Engineering, Tohoku University, Sendai, Japan*

CV-10. Noise Suppression Effectiveness of Fe-Si-Al Magnetic Composite Thick Film on the Signal Transmission Cable. *K. Lee¹, D. Kang¹, I. Byun¹, I. Jeong¹ and S. Kim². R & D Center, Chang Sung Corporation, Incheon, South Korea; 2. Nano-Materials Research Center, Korea Institute of Science and Technology, KIST, Seoul, South Korea*

CV-11. Microwave absorption properties in Bi-substitute Yttrium Iron Garnet. *D. Hung¹, Y. Fu² and Y. Yao³. Information & Telecommunications Engineering, Ming Chuang University, Taipei, Taiwan; 2. Department of Materials Science and Engineering, National Dong Hwa University, Hualien, Taiwan; 3. Department of Materials Engineering, Tatung University, Taipei, Taiwan*

**TUESDAY
MORNING
9:00**

POLIVALENTE

Session CV MICROWAVE MATERIALS AND DEVICES -II (POSTER SESSION)

Masahiro Yamaguchi, Chair

CV-01. Integrated on-chip microstrip lines with Co-Ta-Zr magnetic films. *P. Khalili Amiri¹, B. Rejaei¹, Y. Zhuang¹, M. Vroubel¹, D. Lee², S. Wang² and J. Burghartz^{3,1}. Delft Institute of Microsystems and Nanoelectronics (DIMES), Delft University of Technology, Delft, Netherlands; 2. Department of Materials Science and Engineering, Stanford University, Stanford, CA; 3. Institute for Microelectronics Stuttgart (IMS CHIPS), Stuttgart, Germany*

CV-12. Preparation and characterization of nano-fiber nonwoven textile for electromagnetic wave shielding. *M. Sonehara^{1,2}, T. Sato², M. Takasaki¹, H. Konishi³, K. Yamasawa² and Y. Miura²* *1. Satellite Venture Business Laboratory, Shinshu University, Ueda, Japan; 2. Spin Device Technology Center, Shinshu University, Nagano, Japan; 3. Faculty of Textile Science and Technology, Shinshu University, Ueda, Japan*

**TUESDAY
MORNING
9:00**

POLIVALENTE

**Session CW
CHARACTERIZATION AND MEASUREMENT TECHNIQUES II
(POSTER SESSION)**

Philip Marketos, Chair
Stan Zurek, Chair

CW-01. Characterization of iron magnetic nanoparticles by termomagnetogravimetry. *J.C. Apesteguy¹, S.E. Jacobo¹, C.E. Rodriguez Torres², M.B. Fernández van Raap² and F.H. Sanchez²* *1. Chemistry, Universidad de Buenos Aires, Buenos Aires, Argentina; 2. Physics IFLP (CONICET), FCE, Universidad Nacional de La Plata, La Plata, Argentina*

CW-02. Magnetization reversal study in a permalloy wire with 3 dissimilar trenches by using real-time magnetic force microscopy. *K. Cheng^{1,2}, C. Yu¹, S. Lee¹, Y. Liou¹, Y. Yao³, J. Wu³ and J. Huang²* *1. Institute of Physics., Academia Sinica., Taipei, Taiwan; 2. Department of Materials Science and Engineering, National Tsing-Hua University, Hsinchu, Taiwan; 3. Department of Materials Engineering, Tatung University, Taipei, Taiwan*

CW-03. Diffracted magneto-optical Kerr effects of one-dimensional magnetic gratings. *J. Kim¹, G. Lee¹, Y. Lee¹, J. Rhee² and C. Yoon³* *1. Quantum Photonic Science Research Center and BK21 Program Division of Advanced Research and Education in Physics, Hanyang University, Seoul, South Korea; 2. BK21 Physics Research Division and Department of Physics, Sungkyunkwan University, Suwon, South Korea; 3. Division of Advanced Materials Science, Hanyang University, Seoul, South Korea*

CW-04. Strain induced ferrimagnetism in Mn₂As and Fe₂As thin films. *J. Kim¹, Y. Hwang¹, J. Choi¹ and S. Cho¹* *1. Univ.of Ulsan, Ulsan, South Korea*

CW-05. Electron paramagnetic resonance studies of diluted magnetic semiconductors Si<sub>1-x>Mn<sub>x>Te<sub>1.5> crystals. *Y. Hwang¹, Y. Um¹, J. Choi¹, S. Cho¹, S. Na² and J. Kim²* *1. Physics, University of Ulsan, Ulsan, South Korea; 2. Physics, Pusan National University, Pusan, South Korea*

CW-06. Metallographic Investigations of Co₂FeAl_{1-x}Si_x Heusler-Compounds. *C.G. Blum¹, G.H. Fecher¹, B. Balke¹ and C. Felser¹* *1. Institut für Anorganische und Analytische Chemie, Johannes Gutenberg-University, Mainz, Germany*

CW-07. Magnetic entropy change in La_{0.5}Nd_{0.2}Sr_{0.3}MnO₃ perovskite. *J. Cho¹, S. Ko¹, Y. Ahn¹ and E. Choi²* *1. Chemistry, Konyang University, Nonsan Chungnam, South Korea; 2. Ophthalmic Optics, Konyang University, Daejeon, South Korea*

CW-08. Magnetic behavior and magnetoimpedance effect in Cobalt-based ribbons. *A. Rosales-Rivera¹, M. Gomez-Hermida¹, A. Velasquez¹, D. Muraca² and H. Sirkin²* *1. Laboratorio de Magnetismo y Materiales Avanzados, Universidad Nacional de Colombia, Manizales, Caldas, Colombia; 2. Fisica, Universidad de Buenos Aires, Buenos Aires, Argentina*

CW-09. Correlation between surface magnetic field and Barkhausen noise in grain-oriented electrical steel. *S. Zurek¹, P. Marketos¹, S. Tumanski², H.V. Patel³ and A.J. Moses¹* *1. School of Engineering, Cardiff University, Cardiff, Wales, UK, United Kingdom; 2. Institute of Electrical Theory and Measurements, Warsaw University of Technology, Warsaw, Poland; 3. Industry and Innovation Division, National Physical Laboratory, Middlesex, England, United Kingdom*

CW-10. Comparison of properties of magnetoacoustic emission and mechanical Barkhausen effects for P91 steel after plastic flow and creep. *B. Augustyniak¹, M. Chmielewski¹, L. Piotrowski¹ and Z. Kowalewski²* *1. Gdansk University of Technology, Gdansk, Poland; 2. Polish Academy of Science, IPPT, Warsaw, Poland*

CW-11. Magnetic and microstructural investigation of pipeline steels. *G. Roland¹, E. Jose², A. Jose³, K. Franz⁴, M. Nasir¹, E. Chistian¹, P. Karin¹ and H. Jose³* *1. Inst. of Solid State Physics, Techn. Univ. Vienna, Vienna, Austria; 2. ESIME-Zacatenco, Instituto Politécnico Nacional, Mexico City, Mexico; 3. ESIQIE, Instituto Politécnico Nacional, Mexico City, Mexico; 4. Techn Univ Vienna, Inst. f. Sensor u. Atuatorsysteme, Vienna, Austria*

CW-12. A Pulsed Field Magneto-optic Kerr Effect Magnetometer for Studying Magnetic Thin-Films and Nanostructures. *D. Atkinson¹ and J.A. King¹* *1. Physics, Durham University, Durham, United Kingdom*

CW-13. A novel application of high resolution scanning electron microscopy for perpendicular recording media characterization. *E.T. Yen¹, L. Lee¹, B. Lu¹ and O. Mryasov²* *1. Seagate Technology, Fremont, CA; 2. Seagate Technology, Pittsburg, PA*

CW-14. Magnetic image detection of the stainless-steel welding part inside the multi-layered tube structure. *T. Hayashi^{1,2}, H. Yamada¹, T. Kiwa¹, K. Tsukada¹ and M. Tamazumi³* *1. Graduate School of Natural Science & Technology, Okayama University, Okayama, Japan; 2. Pulstec Industrial Co., Ltd, Hamamatsu, Japan; 3. Uno Kogyo Co.,Ltd, Okayama, Japan*

CW-15. Transient Eddy Current Measurement for the Characterization of Depth and Conductivity of a Conductive Plate. *W. Cheng¹* *1. NDE Center, Japan Power Engineering and Inspection Corporation, Yokohama, Japan*

CW-16. Multidirectional Remanent Flux Leakage Transducers for Evaluation of Stress and Fatigue Loaded Steel Samples. *T. Chady¹ and G. Psuj¹* *1. Department of Electrical and Computer Engineering, Szczecin University of Technology, Szczecin, Poland*

TUESDAY
AFTERNOON
2:30

AUDITORIO A

4:15

Session DA
BIT PATTERNED MEDIA II

Kaizhong Gao, Chair

2:30

DA-01. Understanding Adjacent Track Erasure in Discrete Track Media. *Y. Tang¹, X. Che² and J. Zhu¹. Electrical and Computer Engineering, Carnegie Mellon University, Pittsburgh, PA; 2. Samsung Information Systems America, San Jose, CA*

2:45

DA-02. 10 Tb/in² recording simulations on patterned domain wall assisted media. *A.Y. Dobin¹, H.J. Richter¹, J. Xue¹ and D. Weller¹. Seagate Technology LLC, Fremont, CA*

3:00

DA-03. Patterned media for 10 Tbit/in² utilizing dual-section “ledge” elements. (Invited) *V. Lomakin^{1,2}, B. Livshitz^{1,2}, S. Li^{1,2}, A. Inomata⁴, R. Choi¹ and N. Bertram^{2,3}. 1. ECE, University of California, San Diego, La Jolla, CA; 2. Center for Magnetic Recording Research, University of California, San Diego, La Jolla, CA; 3. Hitachi San Jose Research Center, San Jose, CA; 4. Storage Systems Laboratories, Fujitsu Laboratories Ltd., Kanagawa, Japan*

3:30

DA-04. Characterization of timing jitter in synchronous writing of bit patterned media. *Y. Tang¹ and X. Che¹. Samsung, San Jose, CA*

3:45

DA-05. Formation of multilayered Co/Pd nano-dot array with an areal density of 1 Tb/in². *J. Wi¹, H. Lee¹, K. Lim¹, T. Kim², K. Shin³ and K. Kim¹. 1. Department of Materials Science and Engineering, Seoul National University, Seoul, South Korea; 2. Department of Advanced Materials Engineering, Sejong University, Seoul, South Korea; 3. Future Technology Research Division, Korea Institute of Science and Technology, Seoul, South Korea*

4:00

DA-06. SUB 100 nm FePt NANODOT ARRAYS FOR ULTRAHIGH-DENSITY MAGNETIC RECORDING. *H. Ko¹, P. Alagarsamy¹, K. Lee¹, S. Shin¹, J. Jung² and H. Jung². 1. Physics, KAIST, Daejeon, South Korea; 2. Chemical and Biomolecular Engineering, KAIST, Daejeon, South Korea*

INTERMAG 2008

DA-07. Dot size dependence of magnetization reversal process in L1₀ FePt dot arrays. *D. Wang¹, T. Seki¹, K. Takanashi¹ and T. Shima². 1. Institute for Materials Research, Tohoku University, Sendai, Miyagi, Japan; 2. Faculty of Engineering, Tohoku-gakuin University, Tagajyo, Miyagi, Japan*

4:30

DA-08. Separating dipolar broadening from the intrinsic switching field distribution in perpendicular bit patterned media. *O. Hellwig¹, A. Moser¹, A. Berger^{1,2}, T. Thomson^{1,3}, E. Dobisz¹, Z.Z. Bandic¹, H. Yang¹, D. Kercher¹ and E.E. Fullerton^{1,4}. 1. San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA; 2. CIC Nanogune, Donostia, Spain; 3. University of Manchester, Manchester, United Kingdom; 4. Center for Magnetic Recording Research, University of California at San Diego, La Jolla, CA*

4:45

DA-09. Low Temperature Remanence Loop Measurements of Ion-Milled Patterned Media. *B.D. Belle¹, F. Schedin¹, T.V. Ashworth², E.W. Hill¹, P.W. Nutter¹, H.J. Hug³ and J.J. Miles¹. 1. School of Computer Science, The University of Manchester, Manchester, United Kingdom; 2. Institute fuer Physik, Universitaet Basel, Basel, Switzerland; 3. EMPA, Dübendorf, Switzerland*

5:00

DA-10. Magnetic properties of exchange-coupled composite nanoparticles and nanopatterns. *D. Goll¹, A. Breitling¹ and S. Macke¹. 1. Max-Planck-Institute for Metals Research, Stuttgart, Germany*

5:15

DA-11. Study of gas cluster ion beam planarization for discrete track magnetic disks. *K. Nagato^{1,2}, H. Tani³, Y. Sakane⁴, N. Toyoda⁵, I. Yamada⁵, M. Nakao¹ and T. Hamaguchi¹. 1. The University of Tokyo, Bunkyo-ku, Tokyo, Japan; 2. Japan Society for the Promotion of Science, Chiyoda-ku, Tokyo, Japan; 3. Hitachi Global Storage Technologies Japan Ltd., Odawara-shi, Kanagawa-ken, Japan; 4. Western Digital Media Operations, San Jose, CA; 5. University of Hyogo, Himeji-shi, Hyogo-ken, Japan*

TUESDAY
AFTERNOON
2:30

MADRID

Session DB
SYMPOSIUM ON MAGNETIC MODELING

Oksana Fesenko Chubykalo, Chair

2:30

DB-01. Dynamic edge mode modeling and edge property measurements in magnetic nanostructures. (Invited) *R.D. McMichael^{1,3}, B.B. Maranville^{2,3}, D.W. Abraham⁴, C.A. Ross⁵ and V.P. Chuang⁵. 1. Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD; 2. Center for Neutron Research, NIST, Gaithersburg, MD; 3. Metallurgy Division, NIST, Gaithersburg, MD; 4. IBM Thomas J. Watson Research Center, Yorktown Heights, NY; 5. Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA*

xlix

3:00

2:45

DB-02. Spin injection driven magnetization dynamics: physical insights gained from numerical micromagnetics. (Invited) *D.V. Berkov¹ and J. Miltat²1. Magnetic and Optical Systems, Innovent Technology Development, Jena, Germany; 2. Laboratoire de Physique des Solides, University Paris-Sud & CNRS, Orsay, France*

DC-02. Current-perpendicular-to-plane magnetoresistances of CoFeB-based exchange-biased spin valves and CoFeB/Ru multilayers. *C. Ahn¹, K. Shin¹ and W. Pratt Jr.²1. Center for Spintronics Research, Korea Institute of Science and Technology, Seoul, South Korea; 2. Department of Physics and Astronomy, Michigan State University, East Lansing, MI*

3:30

3:00

DB-03. Hierarchical multi-scale model: application to FePt. (Invited) *U. Nowak¹1. Physics, University of York, York, United Kingdom*

DC-03. Magnetoresistance and switching properties of Co_xFe_{100-x}/Pd-based perpendicular anisotropy single and dual spin valves without exchange bias. *R. Law^{1,2}, R. Sbiaa¹, T. Liew¹ and T. Chong¹1. Data Storage Institute, A*STAR (Agency for Science, Technology and Research), Singapore, Singapore; 2. NUS Graduate School for Integrative Sciences & Engineering, National University of Singapore, Singapore, Singapore*

4:00

DB-04. Micromagnetics of Patterned Media Recording. (Invited) *T. Schrefl¹, A. Goncharov¹, J. Dean¹, G. Hrkac¹ and S. Bance¹1. University of Sheffield, Sheffield, United Kingdom*

3:15

4:30

DC-04. Magnetic structure of domain walls confined in a nano-oxide layer. *K. Matsushita¹, J. Sato¹ and H. Imamura¹1. Nanotechnology Research Institute, AIST, Tsukuba, Ibaraki, Japan*

DB-05. MODELING THE MAGNETIC PROPERTIES OF NANOPARTICLES: FINITE-SIZE, SURFACE AND EXCHANGE BIAS EFFECTS. (Invited) *O. Iglesias^{1,2}, X. Batlle^{1,2} and A. Labarta^{1,2}1. Dpt. Física Fonamental, Universitat de Barcelona, Barcelona, Spain; 2. Institut de Nanociència i Nanotecnologia de la UB (IN2UB), Barcelona, Spain*

3:30

5:00

DC-05. MICROMAGNETIC STUDY ON DOMAIN WALL SIZE FOR NANOCONTACT MAGNETORESISTANCE IN SPIN VALVE STRUCTURE. *M. Takagishi¹, H.N. Fuke¹, S. Hashimoto¹ and H. Iwasaki¹1. Corporate R&D Center, TOSHIBA Corporation, Kawasaki, Japan*

DB-06. Modeling the temperature dependent free energy barrier for magnetization reversal in nanomagnets. (Invited) *T.C. Schulthess¹, C. Zhou¹, O.N. Mryasov², D.M. Nicholson¹, M. Eisenbach¹ and P.R. Kent¹1. Oak Ridge National Laboratory, Oak Ridge, TN; 2. Seagate Research, Pittsburgh, PA*

3:45

DC-06. Effect of surface scattering on magnetoresistance. *X. Chen¹ and R.H. Victora²1. Department of Physics, University of Minnesota, Minneapolis, MN; 2. Department of Electrical & Computer Engineering, University of Minnesota, Minneapolis, MN*

TUESDAY
AFTERNOON
2:30

ROMA

4:00

Session DC GMR IN NANOCONTACTS AND CONSTRICTIONS

Jeff Childress, Chair

2:30

DC-01. Effective resistance mismatch and magnetoresistance of a CPP-GMR system with current-confined-paths. *J. Sato¹, K. Matsushita¹ and H. Imamura¹1. Advanced Industrial Science and Technology, Tsukuba, Japan*

DC-07. CPP-GMR characteristics of full epitaxial spin valves film with alternate monatomic [Fe/Co]_n superlattice. *I. Chu¹, T. Mano¹, M. Doi¹ and M. Sashiki¹1. Department of Electronic Engineering, Tohoku University, Sendai, Japan*

4:15

DC-08. Spin transfer magnetization dynamics in ultra small nanocontacts elaborated by CT-AFM nanolithography. *M. Darques¹, B. Georges¹, A. Ruotolo¹, V. Cros¹, S. Fusil¹, J. Grollier¹, R. Guillemet¹, K. Bouzehouane¹, C. Deranlot¹ and A. Fert¹1. Unite Mixte de Physique CNRS/Thales, Palaiseau, France*

4:30

DC-09. Layered annular magnetic bridges for storage and logic applications. *F.J. Castano¹, B.G. Ng¹, C.H. Nam¹ and C.A. Ross¹*. *Depart. of Material Science and Engineering, MIT, Cambridge, MA*

4:45

DC-10. Investigation of strong biquadratic coupling in Co₂MnSi based trilayer structures. *Y. Sakuraba¹, S. Bosu¹, K. Saito¹, H. Wang¹, S. Mitani¹ and K. Takanashi¹*. *Institute for materials research, Tohoku univ., Sendai, Miyagi, Japan*

5:00

DC-11. CPP magnetoresistance effect through Graphene sheets. *E.W. Hill¹, T.G. Mohiuddin¹, D. Elias¹, A.K. Geim¹, F. Schedin¹, K. Novoselov¹, P. Blake¹ and A. Zhukov¹*. *Centre for Mesoscience and Nanotechnology, The University of Manchester, Manchester, United Kingdom*

5:15

DC-12. Magnetoresistance and energy model of Alq₃-based spintronic devices. *L.E. Hueso^{1,2}, V. Dediu², I. Bergenti², A. Riminucci², P. Graziosi², F. Borgatti², F. Cassoli³, Y. Zhan², C. Taliani² and M.P. de Jong⁴*. *Department of Physics, University of Leeds, Leeds, United Kingdom; 2. ISMN, CNR, Bologna, Italy; 3. IMEM, CNR, Parma, Italy; 4. Nanoelectronics Group, University of Twente, Enschede, Netherlands*

TUESDAY
AFTERNOON
2:30

PARIS

Session DD PERMANENT MAGNET MACHINES II

Antero Arkkio, Chair

2:30

DD-01. A novel ‘pseudo’ direct-drive brushless permanent magnet machine. *K. Atallah¹, J. Rens¹, S. Mezani¹ and D. Howe¹*. *Electronic & Electrical Engineering, The University of Sheffield, Sheffield, United Kingdom*

2:45

DD-02. Design optimization of a single-phase permanent magnet synchronous generator. *J. El Hayek¹, J. Brünisholz² and P. Pittet³*. *Industrial Technologies, University of Applied Sciences Western Switzerland, Fribourg, Switzerland; 2. ATPS, ABB, Turgi, Switzerland; 3. Power Service, ALSTOM Ltd, Baden, Switzerland*

3:00

DD-03. An Ultra-High Speed PM Motor for Small Milling Machine Applications. *J. Asama¹, K. Maruyama¹, Y. Yanagihara¹ and A. Chiba¹*. *Electrical Engineering, Tokyo University of Science, Noda, Chiba, Japan*

3:15

DD-04. Design and analysis of a novel hybrid excitation synchronous machine with asymmetrically stagger permanent magnet. *Y. Chengfeng¹, L. Heyun¹, G. Jian¹ and Z. Ziqiang²*. *School of Electrical Engineering, Southeast University, Nanjing, China; 2. Department of Electronic and Electrical Engineering, University of Sheffield, Sheffield, United Kingdom*

3:30

DD-05. Novel axial flux permanent magnet synchronous machines with segmented and laminated stator configuration. *W. Fei¹ and P. Luk¹*. *Department of Aerospace Power and Sensors, DCMT Cranfield University, Shrivenham, Wiltshire SN6 8LA, United Kingdom*

3:45

DD-06. Modeling of a linear and rotative permanent magnet actuator. *G. Krebs¹, A. Tounzi¹, B. Pauwels², D. Willemot² and F. Piriou¹*. *L2EP-USTL, Villeneuve d'Ascq, France; 2. Psicontrol Mechatronics, Ieper, Belgium*

4:00

DD-07. Analysis and experimental verification of a single phase, quasi-Halbach magnetised tubular permanent magnet motor with non-ferromagnetic supporting tube. *J. Wang¹, T. Ibrahim¹ and D. Howe¹*. *Electronic and Electrical Engineering, University of Sheffield, Sheffield, United Kingdom*

4:15

DD-08. Optimization of a sea wave energy harvesting electromagnetic device. *M. Trapanese¹*. *Dipartimento di Ingegneria Elettrica, Elettronica e delle Telecomunicazioni, University of Palermo, Palermo, Italy*

4:30

DD-09. Design and characteristic analysis on the short-stator linear synchronous motor for high-speed Maglev propulsion. *H. Cho¹, H. Sung¹, S. Sung¹, D. You² and S. Jang²*. *Maglev Research Team, Korea Institute of Machinery and Materials, Daejeon, South Korea; 2. Electrical Engineering, Chungnam National University, Daejeon, South Korea*

4:45

DD-10. Eddy-current stator solid steel back-iron losses in small rotary brushless permanent magnet machines. *J.J. Paulides¹, K.J. Meessen¹ and E.A. Lomonova¹ I. Technical university Eindhoven, Eindhoven, Netherlands*

5:00

DD-11. Experimental Method and Verification to Characterize the Unbalanced Magnetic Force in Electric Motors. *C. Lee¹ and G. Jang¹ I. Dept. of Mechanical Engineering, PREM Lab., Hanyang University, Seoul, South Korea*

5:15

DD-12. Study of an electromagnetic gearbox involving two PM synchronous machines using 3D-FEM. *M. Aubertin¹, A. Tounzi¹ and Y. Le Ménach¹ I. L2EP - USTL, Villeneuve d'Ascq, France*

**TUESDAY
AFTERNOON
2:30**

LONDRES

Session DE SOFT MAGNETIC WIRES

Kleber Pirola, Chair

2:30

DE-01. Domain wall propagation in thin magnetic wires. (Invited) *R. Varga¹, K. Richter¹, A. Zhukov² and V. Larin³ I. Institute of Physics, Faculty of Sciences, UPJS, Kosice, Slovakia; 2. Dept. Fisica de Materiales, Fac. Química, UPV/EHU, San Sebastian, Spain; 3. MFTI, Kishinev, Moldova*

3:00

DE-02. Domain wall propagation in nearly zero magnetostrictive amorphous microwires. *H. Chiriac¹, T. Óvári¹ and M. Tibu¹ I. National Institute of Research and Development for Technical Physics, Iasi, Romania*

3:15

DE-03. Electromagnetic wave absorbing material based on magnetic microwires. *P. Marin^{1,2}, D. Cortina³ and A. Hernando^{1,2} I. Instituto de Magnetismo Aplicado, Universidad Complutense de Madrid, Las Rozas, Madrid, Spain; 2. Fisica de Materiales, Universidad Complutense de Madrid, Madrid, Spain; 3. Micromag 2000, S.L., Las Rozas, Spain*

3:30

DE-04. Experimental determination of relation between helical anisotropy and torsion stress in amorphous magnetic microwires. *A. Chizhik¹, A. Zhukov¹, J. Blanco², J. Gonzalez¹, P. Gawronski³ and K. Kulakowski³ I. Dpto. Fisica de Materiales, Universidad del Pais Vasco, San Sebastian, Gipuzcoa, Spain; 2. Departamento Fisica Aplicada I, EUPDS, Universidad del Pais Vasco, San Sebastian, Gipuzcoa, Spain; 3. Faculty of Physics & Applied Computer Science, AGH University of Science & Technology, Cracow, Poland*

3:45

DE-05. Circular magnetoelastic anisotropy induced in the nucleus of FeSiB/CoNi soft-hard biphasic microwire. *J. Torrejón¹, M. García-Hernández¹, G. Infante¹, K.J. Merazzo¹ and G. Badini¹ I. Magnetism, ICMM (CSIC), Madrid, Madrid, Spain*

4:00

DE-06. Temperature behaviour of magnetic anisotropy of nanocrystallized Finemet-based glass-coated microwires. *V. Dubuget^{1,2}, A. Adenot-Engelvin¹ and F. Bertin¹ I. CEA, Monts, France; 2. LEMA, UMR CNRS 6157, TOURS, France*

4:15

DE-07. Temperature Dependence of the Magnetization Reversal Process and Domain Structure in Fe_{77.5}-xNi_xSi_{7.5}B₁₅ Magnetic Microwires. *J. Olivera^{1,2}, M. Sánchez¹, V.M. Prida¹, R. Varga², V. Zhukova³, A.P. Zhukov³ and B. Hernando¹ I. Fisica, Universidad de Oviedo, Oviedo, Asturias, Spain; 2. Inst. Physics, Fac. Sci., UPJS, Park Angelinum, Kosice, Slovakia; 3. Dpto. de Fisica de Materiales, Fac. Químicas, Universidad del Pais Vasco, San Sebastián, Guipúzcoa, Spain*

4:30

DE-08. Synthesis and Characterization of Fe/FeOx Core/Shell Nanowires. *J. Lee¹, J. Lee¹, K. Jeon², J. Wu¹, H. Kim¹, J. Lee¹, Y. Suh² and Y. Kim¹ I. Department of Materials Science and Engineering, Korea University, Seoul, Seoul, South Korea; 2. Fusion Biotechnology Research Center, Korea Research Institute of Chemical Technology, Daejeon, South Korea*

4:45

DE-09. Structure and Magnetic properties of electrodeposited cobalt nanowires in polycarbonate membrane. *S.r. Vishnubhotla¹, C. Kim¹ and S. Yoon² I. Chungnam National University, Daejeon, South Korea; 2. Andong National University, Daejeon, South Korea*

5:00

DE-10. Structural and thermal behaviour of nanocrystalline nanowires. *M.J. Vieyra¹, T. Meydan¹ and F. Borza¹ I. Cardiff School of Engineering, Wolfson Centre for Magnetism, Cardiff, South Glamorgan, United Kingdom*

5:15

DE-11. Silicon steel wire with low magnetic losses. *T. Yonamine*¹, M. Fukuhara¹, N.A. Castro², F.G. Landgraf³ and F.P. Missell^{1,4}. *1. Divisão de Metrologia de Materiais, Instituto Nacional de Metrologia, Normalização e Qualidade Industrial-INMETRO, Duque de Caxias, Rio de Janeiro, Brazil; 2. Instituto de Pesquisas Tecnológicas-IPT, São Paulo, São Paulo, Brazil; 3. Departamento de Metalurgia e Materiais, Escola Politécnica da Universidade de São Paulo - EPUSP, São Paulo, São Paulo, Brazil; 4. Centro de Ciências Exatas e Tecnológicas, Universidade de Caxias do Sul, Caxias do Sul, Rio Grande do Sul, Brazil*

**TUESDAY
AFTERNOON
2:30**

BERLIN

**Session DF
RECORDING SYSTEMS AND SERVO I**
Aleksandar Kavcic, Chair

2:30

DF-01. A proposed “747” test to establish the areal-density capability of a magnetic recording system based only on data-block failure rate. *Z. Jin*¹, M. Salo¹ and R. Wood¹. *1. HDD AdTech, Hitachi GST, San Jose, CA*

2:45

DF-02. Probabilistic Analysis of Off-track Capability for Higher Track Density Disk Drives. *K. Aruga*¹, H. Ueno¹, T. Iwase¹ and Y. Ogawa¹. *1. HDD division (E3-333), Fujitsu Limited, Kawasaki, 211-8588, Japan*

3:00

DF-03. Analysis of cross track response using a three dimensional model for Perpendicular Read Heads. *Z. Liu*¹, B. Chen¹ and S. Zhang¹. *1. Data Storage Institute, Singapore, Singapore*

3:15

DF-04. The reliability evaluation of piezoelectric micro actuators with application in hard disk drives. *Z. He*¹, H. Loh² and E. Ong¹. *1. A*Star, Data Storage Institute, Singapore, Singapore; 2. Mechanical Engineering Department, National University of Singapore, Singapore, Singapore*

3:30

DF-05. A slider with an integrated microactuator (SLIM) for second stage actuation in hard disc drives. *H.H. Gatzel*¹, P.J. Freitas², E. Obermeier³ and J. Robertson⁴. *1. Institute for Microtechnology, Leibniz Universitaet Hannover, Garbsen, Germany; 2. INESC-MN, Lisboa, Portugal; 3. Microsensor & Actuator Technology, Berlin University of Technology, Berlin, Germany; 4. Department of Engineering, University of Cambridge, Cambridge, United Kingdom*

3:45

DF-06. Integrated electromagnetic second stage micro actuator for a hard disk recording head. *D. Dinulovic*¹, H. Saalfeld¹ and H.H. Gatzel¹. *1. Institute for Microtechnology, Leibniz Universitaet Hannover, Garbsen, Germany*

4:00

DF-07. Characterization of timing based servo signals. *G. Cherubini*¹, *R.D. Cideciyan*¹, E. Eleftheriou¹ and P.V. Koeppel². *1. IBM Research, Zurich Research Laboratory, Rueschlikon, Switzerland; 2. IBM Systems and Technology Group, San Jose, CA*

4:15

DF-08. Evaluation of printed servo patterns. *B. Baker*¹. *1. Redwood Technology, Redwood City, CA*

4:30

DF-09. Overwrite performance change due to air-flow induced vibration of head stack assembly. *E. Jang*¹ and J. Chang¹. *1. HDD R&D, Samsung Information Systems America, San Jose, CA*

4:45

DF-10. Reduced Order Models for Efficient Simulation of Hard Disk Drive Operational Shock Responses. *W. Lin*¹, E. Ong¹, J. Mou¹, E. Ong¹ and S. Hu². *1. Data Storage Institute, Singapore, Singapore; 2. Nitto Denko Corporation, Kameyama, Japan*

5:00

DF-11. A Case for Redundant Arrays of Hybrid Disks (RAHD). *F. Wang*¹, N. Helian¹, D. Deng¹, S. Wu¹, C. Liao¹, M. Rashidi¹ and A. Parker². *1. Centre for Grid Computing, Cambridge-Cranfield HPCF, Cranfield, United Kingdom; 2. Cavendish Laboratory, Cambridge University, Cambridge, United Kingdom*

5:15

3:30

DF-12. What is the future of hard disk drive, death or rebirth? *Y. Deng*¹, *F. Wang*¹ and *N. Helian*²*I. School of Engineering, Cranfield University, Bedfordshire, United Kingdom; 2. London Metropolitan University, London, United Kingdom*

DG-05. Microwave radiometry for early breast cancer detection. *M.P. Costin*^{1,2} and *O. Baltag*²*I. Computer Science Institute, Romanian Academy, Iasi, Romania; 2. Faculty of Biomedical Engineering, University of Medicine and Pharmacy, IASI, IASI, Romania*

TUESDAY
AFTERNOON
2:30

AMSTERDAM

3:45

DG-06. Microwave resonator devices for ferromagnetic resonance detection of magnetic beads. *S. Ghionea*¹, *P. Dhagat*¹ and *A. Jander*¹*I. Department of Electrical Engineering and Computer Science, Oregon State University, Corvallis, OR*

4:00

Session DG
LIFE SCIENCES: TECHNIQUES AND INSTRUMENTATION I
Quentin Pankhurst, Chair

DG-07. Magnetic Immunoassays – New Methods of Biochemical Diagnostics Based on Detection of Magnetic Nanoparticles by Non-Linear Magnetization. *P. Nikitin*¹, *P. Vetoshko*², *M. Nikitin*³ and *T. Ksenivich*¹*I. Natural Science Center, General Physics Institute, Russian Academy of Sciences, Moscow, Russian Federation; 2. Institute of Radioengineering and Electronics, Russian Academy of Sciences, Moscow, Russian Federation; 3. Department of Molecular & Biological Physics, Moscow Institute of Physics & Technology, Dolgoprudny, Moscow Region, Russian Federation*

4:15

DG-01. Signal and Power Transmission in Real-time Internal Irradiation Dose Measurement System. *K. Shinohe*¹, *T. Takura*¹, *F. Sato*¹, *H. Matsuki*¹, *S. Yamada*² and *T. Sato*³*I. Graduate School of Engineering, Tohoku University, Sendai, Miyagi, Japan; 2. Graduate School of Medicine, Tohoku University, Sendai, Miyagi, Japan; 3. NEC Torkin Corp., Sendai, Miyagi, Japan*

DG-08. Giant magnetoresistance sensors for lateral flow tests. *C. Marquina*¹, *J.M. De Teresa*¹, *J. Sesé*², *V. Grazú*², *B. Velasco*³, *P. Freitas*⁴ and *R. Ibarra*^{1,2}*I. Instituto de Ciencia de Materiales de Aragon, CSIC-Universidad de Zaragoza, Zaragoza, Spain; 2. Instituto de Nanociencia de Aragon, Universidad de Zaragoza, Zaragoza, Spain; 3. CerTest Biotec, Zaragoza, Spain; 4. INESC, MN, Inst Engn Sistemas Computadores Microsyst & Nanot, Lisbon, Portugal*

4:30

DG-02. Imaging of electric permittivity and conductivity using MRI. *M. Sekino*¹, *S. Tatara*¹ and *H. Ohsaki*¹*I. Department of Advanced Energy, Graduate School of Frontier Sciences, The University of Tokyo, Kashiwa, Chiba, Japan*

DG-09. Magnetic-Entasis Biorecognition Platform: Self Assembly of Magnetic Nanoparticles for Detection of Magnetically Labeled Biomolecules. *Y. Yamamoto*¹, *T. Yamanaka*¹, *Y. Morimoto*¹, *S. Sakamoto*³, *Y. Mochiduki*³, *M. Abe*⁴, *H. Handa*³ and *A. Sandhu*^{1,2}*I. Quantum Nanoelectronics Research Center, Tokyo Institute of Technology, Tokyo, Japan; 2. Department of Electrical and Electronic Engineering, Tokyo Institute of Technology, Tokyo, Japan; 3. Graduate School of Bioscience and Biotechnology, Tokyo Institute of Technology, Tokyo, Japan; 4. Department of Physical Electronics, Tokyo Institute of Technology, Tokyo, Japan*

4:45

DG-03. Optimization of coil structure in resonant circuit implant for hyperthermia using MRI. *J. Kunisaki*¹, *M. Shimizu*¹, *K. Kamio*¹, *S. Hiroe*¹, *T. Yamada*¹ and *Y. Takemura*¹*I. Division of Electrical and Computer Engineering, Yokohama National University, Yokohama, Japan*

DG-10. Magnetic bar array with linker technology for detection and investigation of non-magnetic molecules. *D. Lee*¹, *L.A. Roberts*², *E. Peroziello*³, *R. Fontana*⁴, *S. Maat*⁴, *M. Nemat-Gorgani*², *S. Hoon*² and *R.L. White*¹*I. Dept. of Materials Science and Engineering, Stanford University, Stanford, CA; 2. Stanford Genome Technology Center, Stanford University, Stanford, CA; 3. Center for Integrated Systems, Stanford University, Stanford, CA; 4. Hitachi Global Storage Technologies, San Jose, CA*

3:15

DG-04. Calculation of minimum parameters required for low-field low-size nano nuclear magnetic resonance (nanoNMR). *P. Gomez*^{1,2}, *S. Khizroev*² and *D. Litvinov*³*I. Electrical Engineering, Florida International University, Miami, FL; 2. Electrical Engineering, University of California Riverside, Riverside, CA; 3. Electrical Engineering, University of Texas, Houston, TX*

TUESDAY
AFTERNOON
2:30

POLIVALENTE

Session DL
ULTRATHIN FILMS AND SURFACE EFFECTS I
(POSTER SESSION)
Alexandra Mougin, Chair

- DL-01. Voltage control of magnetic anisotropy in an ultrathin Fe film.** *T. Maruyama¹, K. Ohta¹, N. Toda¹, T. Nozaki¹, T. Shinjo¹, M. Shiraishi¹ and Y. Suzuki¹*. *Engineering science, Osaka university, Toyonaka, Japan*
- DL-02. Angular dependence of two magnon scattering in ultrathin ferromagnets.** *P. Landeros¹, R.E. Arias² and D.L. Mills³*. *1. Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Valparaíso, Chile; 2. Departamento de Física, Universidad de Chile, Santiago, Chile; 3. Department of Physics and Astronomy, University of California, Irvine, CA*
- DL-03. CEMS study of epitaxial Co₂Cr_{0.6}Fe_{0.4}Al thin films.** *V. Ksenofontov¹, C. Herbolt², M. Jourdan² and C. Felser¹*. *1. Institute of Inorganic and Analytical Chemistry, Johannes Gutenberg-University Mainz, 55099 Mainz, Germany; 2. Institute of Physics, Johannes Gutenberg - University, 55099 Mainz, Germany*
- DL-04. Morphology-induced oscillations of the electron-spin motion in Fe films on Ag(001).** *L. Tati Bismaths¹, L. Joly², F. Scheurer¹ and W. Weber¹*. *1. Institut de Physique et Chimie des Matériaux de Strasbourg, Strasbourg, France; 2. Swiss Light Source, Villigen, Switzerland*
- DL-05. Ferromagnetic Resonance of Disordered FePt Thin Films.** *J. Gómez¹, M. Vásquez Mansilla¹ and A. Butera¹*. *1. Centro Atómico Bariloche and Instituto Balseiro, Bariloche, Río Negro, Argentina*
- DL-06. Magnetization processes in ultrathin Co film grown on stepped Si(111) substrate.** *A. Stupakiewicz^{1,2}, A. Fleurence², A. Maziewski¹, T. Maroutian², P. Gogol², B. Bartenlian², R. Mégy² and P. Beauvillain²*. *1. University of Białystok, Białystok, Poland; 2. Institut d'Electronique Fondamentale, Université Paris XI, CNRS, UMR 8622, Orsay, France*
- DL-07. Effects of Co/Sm composition on the ordered phase formation in Sm-Co thin films grown on Cu(111) single-crystal underlayers.** *Y. Nukaga¹, M. Ohtake¹, F. Kirino² and M. Futamoto¹*. *Faculty of Science and Engineering, Chuo University, Tokyo, Japan; 2. Graduate School of Fine Arts, Tokyo National University of Fine Arts and Music, Tokyo, Japan*
- DL-08. Analysis of the multiferroic properties in BiMnO₃ epitaxial thin films.** *M. Grizalez^{1,2}, J.C. Caicedo² and P. Prieto²*. *1. Universidad de la Amazonia, Florencia, Caquetá, Colombia; 2. Universidad del Valle, Cali, Valle del Cauca, Colombia; 3. Centro de Excelencia en Nuevos Materiales, Cali, Valle del Cauca, Colombia*
- DL-09. Electric and magnetic properties of multiferroic BiFeO₃ and YMnO₃ thin films.** *J.A. Zapata¹, J. Narvaez¹, W. Lopera¹, M.H. Gómez¹ and P. Prieto²*. *1. Physics, Universidad del Valle, Cali, Valle del Cauca, Colombia; 2. Centro de Excelencia en Nuevos Materiales, Cali, Valle del Cauca, Colombia*

INTERMAG 2008

DL-10. Graphene/Ni(111) system: Spin- and angle-resolved photoemission studies. *Y.S. Dedkov¹, M. Fonin², U. Rüdiger² and C. Laubschat¹*. *1. TU Dresden, Dresden, Germany; 2. University of Konstanz, Konstanz, Germany*

DL-11. Epitaxial growth of SrM(001) film on Au(111). *A. Kaewrawang¹, G. Ishida¹, X. Liu¹ and A. Morisako¹*. *Information Engineering, Shinshu University, Nagano, Japan*

DL-12. Surface characteristics of atomic-level Co-Cu thin film system : Molecular dynamics simulation. *B. Kim¹, K. Chae¹ and Y. Chung¹*. *1. Department of Materials Science and Engineering, Hanyang University, Seoul, South Korea*

DL-13. Measurement of interface pinning at a metallic ferromagnetic thin film interface using inductive magnetometry. *K.J. Kennewell¹, M. Ali², M. Kostylev¹, D. Greig², B.J. Hickey² and R.L. Stamps¹*. *1. School of Physics, University of Western Australia, Crawley, WA, Australia; 2. Department of Physics & Astronomy, University of Leeds, Leeds, United Kingdom*

DL-14. Study of the magnetic properties of MnAs thin films as a function of the film thickness. *J. Milano^{1,2}, L.B. Steren^{1,2}, A. Repetto Llamazares², V. Garcia³, M. Marangolo³, M. Eddrief³ and V.H. Etgens³*. *1. CNEA-CONICET, San Carlos de Bariloche, Río Negro, Argentina; 2. Instituto Balseiro, UNCuyo, San Carlos de Bariloche, Río Negro, Argentina; 3. Institut des NanoSciences de Paris, INSP, Université Pierre et Marie Curie-Paris 6, Université Denis Diderot-Paris 7, CNRS UMR 7588, Paris, France*

DL-15. Fe-doping Effect on Morphologic and Magnetotransport Properties of La₂/3Ca₁/3Fe_{1-y}MnyO₃ thin films. *O.L. Arnache Olmos¹, A. Hoffmann², D.A. Giratá¹ and M.E. Gomez²*. *1. Instituto de Física, Universidad de Antioquia, Medellín, Antioquia, Colombia; 2. Materials Science Division, Argonne National Laboratory, Argonne, IL; 3. Department of Physics, Universidad del Valle, Cali, Valle, Colombia*

TUESDAY
AFTERNOON
2:30

Session DM
ULTRATHIN FILMS AND SURFACE EFFECTS II
(POSTER SESSION)
Juergen Fassbender, Chair

DM-01. A study on surface magneto-optical Kerr effect of ultra thin Fe films on various GaAs substrates. *W. Guan¹, T. Shen¹ and G. Jones¹*. *1. Joule Physics Laboratory, University of Salford, Salford, United Kingdom*

DM-02. Composite oxide buffer layers for (002) Fe/MgO/Fe magnetic tunneling junctions. *H. Huang¹, P. Huang¹ and C. Lai¹*. *1. Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan*

DM-03. Stripe magnetic domains in sputtered permalloy films. *D. Hrabovsky¹, M. Rubio-Roy², J. Caicedo-Roque¹, E. Bertan² and J. Fontcuberta¹* *1. ICMAB - CSIC, Bellaterra, Spain; 2. FAO, University of Barcelona, Barcelona, Spain*

DM-04. Influence of capping layers on magnetic anisotropy in Fe/MgO/GaAs(100) ultrathin films. *P. Wong¹, W. Zhang¹, Y. Xu¹, Y. Fu², Z. Huang², Y. Zhai², Y. Xu³, H. Zhai³ and S.M. Thompson⁴* *1. Spintronics and Nanodevice Laboratory, Department of Electronics, University of York, York, United Kingdom; 2. Department of Physics, Southeast University, Nanjing, China; 3. Center for Materials Analysis, Nanjing University, Nanjing, China; 4. Department of Physics, University of York, York, United Kingdom*

DM-05. Calculation of resonant standing spin wave mode response induced by a coplanar stripline. *K.J. Kennewell¹, M. Kostylev¹ and R.L. Stamps¹* *1. School of Physics, University of Western Australia, Crawley, WA, Australia*

DM-06. Ga⁺ ion irradiation-induced out-of-plane magnetization in Pt/Co(3nm)/Pt films. *J. Jaworowicz^{1,2}, M. Kisielski^{1,2}, A. Maziewski^{1,2}, I. Sveklo¹, J. Jamet¹, J. Ferré¹, . Mouglin¹, N. Vernier¹ and J. Fassbender³* *1. Laboratoire de Physique des Solides, Orsay, France; 2. Laboratory of Magnetism, University of Bialystok, Bialystok, Poland; 3. Institute of Ion Beam Physics and Materials Research, Forschungszentrum Dresden-Rossendorf, Dresden, Germany*

DM-07. Intermixing and spin-pumping effects on Gilbert damping of CoFeB. *S. Huang¹, C. Wang¹, J. Song¹, C. Lai¹, W. Chen², S. Yang², K. Shen² and H. Bor³* *1. Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan; 2. Electronics Research and Service Organization, Industrial Technology Research Institute, Hsinchu, Taiwan; 3. Materials and Electro-Optics Research Division, Chuang-Shan institute of Science and Technology, Taoyoun, Taiwan*

DM-08. FMR Studies of Ga_{1-x}Mn_xAs thin layers with x>0.1. *K. Khazen¹, M. Cubukcu¹, H. von Bardeleben¹, J. Cantin¹, S. Ohya^{2,3}, K. Ohno² and M. Tanaka²* *1. Institut des NanoSciences de Paris(INSP)Université- Paris 6, UMR 7588 au CNRS, Paris, Ile de France, France; 2. Electronic Engineering, The University of Tokyo, Tokyo, Japan; 3. Japan Science and Technology Agency, Kawaguchi-shi, Saitama, Japan*

DM-09. Large scale surface magnetic domains in magnetite thin films studied by spin-polarized scanning electron microscopy. *E. Kaji¹, A. Subagyo¹ and K. Sueoka¹* *1. Graduate School of Information Science and Technology, Hokkaido University, Sapporo, Japan*

DM-10. Determination of the Gilbert damping factor in Ga_{0.93}Mn_{0.07}As/GaAs Thin Layers. *K. Khazen¹, M. Cubukcu¹, H. von Bardeleben¹, J. Cantin¹, V. Novak², K. Olejnik² and M. Cukr²* *1. Institut des NanoSciences de Paris(INSP)Université- Paris 6, UMR 7588 au CNRS, Paris, Ile de France, France; 2. Institute of Physics AS CR, Praha, Czech Republic*

DM-11. Experimental evidence for bulk and interfacial contributions to static and dynamic properties of Py/AIS₂SO₃S₃. *C. Le Graet¹, D.T. Dekadjevi¹, S. Pogossian¹, D. Spenato¹ and J. Ben Youssef¹* *1. Physics, LMB/UBO/CNRS, Brest, Bretagne, France*

DM-12. Asymmetry of polycrystalline Fe thin films showing bcc (110) growth orientation on glass substrates using second-harmonic generation. *F. Lee¹, J. Jeong¹, H. Lee¹, K. Lee¹, J. Kim¹ and S. Shin¹* *1. department of Physics, Korea Advanced Institute of Science, Daejeon, South Korea*

DM-13. Transition to antiferromagnetic interlayer coupling at the Cu spacer thickness of 2 nm in bottom spin valve films with Co_{1-x}Fe_x/Cr-NOL. *K. Sawada¹, K. Futatsukawa¹, M. Doi¹, N. Hasegawa² and M. Sahashi¹* *1. Tohoku university, Sendai, Japan; 2. ALPS electric corporation, Niigata, Japan*

DM-14. The Effect of CoFe Surface Pre-Oxidation on Magnetic Tunnel Junctions. *P. Pong¹ and W.F. Egelhoff¹* *1. Magnetic Materials Group, National Institute of Standards and Technology, Gaithersburg, MD*

**TUESDAY
AFTERNOON
2:30**

POLIVALENTE

**Session DN
MAGNETIC MICROSCOPY II
(POSTER SESSION)
Manfred Rührig, Chair**

DN-01. Time-resolved magnetization dynamics in magnetic microstructures. *D. Bayer¹, J. Miguel², J. Sanchez-Barriga³, J. Kurde², M. Piantek², F. Kronast³, M. Cinchetti¹, B. Heitkamp³, H. Dürr³, W. Kuch² and M. Aeschlimann¹* *1. University of Kaiserslautern, Kaiserslautern, Germany; 2. Freie Universität Berlin, Berlin, Germany; 3. BESSY GmbH, Berlin, Germany*

DN-02. Anisotropic x-ray magnetic linear dichroism at Fe, Co and Ni L edges: Interfacial coupling revisited. *G. van der Laan¹ and E. Arenholz²* *1. Diamond Light Source, Didcot, Oxfordshire, United Kingdom; 2. ALS, Berkeley, CA*

DN-03. Topological hysteresis in superconductors and ferromagnets. *R. Prozorov^{2,1} and P.C. Canfield^{2,1}* *1. Physics and Astronomy, Iowa State University, Ames, IA; 2. Ames Laboratory, Ames, IA*

DN-04. Avalanches through windows: multiscale visualization in magnetic thin films. *G. Durin¹, A. Magni¹, S. Zapperi^{2,3} and J.P. Sethna⁴* *1. Istituto Nazionale di Ricerca Metrologica, Torino, Italy; 2. Dep. of Physics, University of Modena and Reggio Emilia, CNR-INFM National Center on nanoStructures and bioSystems at Surfaces (S3), Modena, Italy; 3. ISI foundation, Torino, Italy; 4. Physics Department, LASSP, Cornell University, Ithaca, NY*

DN-05. Direct observation on a systematic change of the magnetic domain structure with temperature in 50 nm-MnAs/GaAs(001). *J. Kim¹, Y. Lee¹, K. Ryu², S. Shin² and H. Akinaga³* *1. Quantum Photonic Science Research Center and BK21 Program Division of Advanced Research and Education in Physics, Hanyang University, Seoul, South Korea; 2. Department of Physics and Center for Nanospinics of Spintronic Materials, Korea Advanced Institute of Science and Technology, Daejeon, South Korea; 3. Nanotechnology Research Institute, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan*

DN-06. Magnetic domain structure coupled with temperature and applied voltage in multiferroic $\text{Bi}_{0.7}\text{Dy}_{0.3}\text{FeO}_3$ thin films. *V.R. Palkar¹, P. Kovur¹, S.P. Dattagupta¹ and S. Bhattacharya²* *1. Electrical Engineering, Indian Institute of Technology Bombay, Mumbai, Maharashtra, India; 2. Condensed Matter Physics, Tata Institute of Fundamental Research, Mumbai, Maharashtra, India*

DN-07. A detailed magnetization reversal in a single Ni-Fe elliptical dot with several dot sizes. *Y. Endo¹, H. Fujimoto², R. Nakatani^{2,3} and M. Yamamoto²* *1. Dept. of Electrical and Communication Engineering, Tohoku University, Sendai, Japan; 2. Dept. of Materials Science and Engineering, Osaka University, Suita, Japan; 3. Center for Atomic and Molecular Technologies, Osaka University, Suita, Japan*

DN-08. High-resolution MFM imaging of in-plane magnetic field using transient oscillation. *H. Saito¹, G. Egawa¹, S. Ishio¹ and G. Li²* *1. Faculty of Engineering and Resource Science, Akita University, Akita, Japan; 2. School of Physics Science & Technology, Southwest University, Chongqing, China*

DN-09. Characterization of coercivity of magnetic force microscopy probes. *M. Jaafar¹, A. Jacas¹, W. Rosa¹ and A. Asenjo¹* *1. Instituto de Ciencia de Materiales de Madrid, ICMM-CSIC, Madrid, Spain*

DN-10. Calibration of MFM probe tips for measurements in external in-plane magnetic fields. *A. Ehresmann¹, T. Weis¹, D. Engel¹, V. Höink², J. Schmalhorst² and G. Reiss²* *1. Institute of Physics and Centre for Interdisciplinary Nanostructure Science and Technology (CINSA), University of Kassel, Kassel, Germany; 2. Thin Films and Nanostructures, Department of Physics, University of Bielefeld, Bielefeld, Germany*

DN-11. An experimental investigation of the magnetically active volume in a magnetic force microscopy tip. *N.E. Mateen¹, M. Gibbs¹ and M. Rainforth¹* *1. Department of Engineering Materials, University of Sheffield, Sheffield, United Kingdom*

DN-12. Plateau probes to enhance the capabilities of magnetic force microscopy. *N. Amos¹, R. Ikkawi¹, R. Fernandez¹, A. Lavrenov¹, A. Krichevsky¹, D. Litvinov² and S. Khizroev¹* *1. Electrical Engineering, University of California, Riverside, Riverside, CA; 2. Center for Nanomagnetic Systems, University of Houston, Houston, TX*

DN-13. Fabrication of Magnetic Force Microscopy Tips via Electrodeposition and Focused Ion Beam Milling. *O. Cespedes¹, A. Luu¹, F.F. Rhen¹ and J.D. Coey¹* *1. Physics Department, Trinity College Dublin, Dublin, Ireland*

DN-14. Contact Mode Scanning Hall Probe Microscopy. *T. Ohashi¹, H. Osawa¹ and A. Sandhu^{1,2}* *1. Quantum Nanoelectronics Research Center, Tokyo Institute of Technology, Tokyo, Japan; 2. Electrical and Electronic Engineering, Tokyo Institute of Technology, Tokyo, Japan*

DN-15. Variable Temperature-Scanning Hall Probe Microscopy (VT-SHPM) with GaN/AlGaN Two-Dimensional Electron Gas (2DEG) Micro Hall Sensors in 4-400K range, Using Novel Quartz Tuning Fork AFM Feedback. *R. Akram¹, M. Dede¹ and A. Oral¹* *1. Department of Physics, Bilkent University, 06800, Ankara, Turkey*

**TUESDAY
AFTERNOON
2:30**

POLIVALENTE

**Session D0
MAGNETO-OPTIC MATERIALS AND DEVICES
(POSTER SESSION)
Jaroslav Hamrle, Chair**

DO-01. Optical reading from videotapes using magnetic garnet film. *M. Kishida¹, N. Hayashi¹, K. Iwasaki², H. Umezawa² and T. Nomura³* *1. Science and Technical Research Laboratories, NHK (Japan Broadcasting corporation), Tokyo, Japan; 2. Research & Development Division, FDK Corporation, Sizuoka, Japan; 3. Department of Electrical, Electronics and Information Engineering, Shizuoka Institute of Science and Technology, Sizuoka, Japan*

DO-02. The influence of the implantation on the magneto-optical properties of $(\text{YBiCaSmLu})_3(\text{FeGeSi})_5\text{O}_{12}$ surface. *L. Kalandadze¹* *1. Batumi State University, Batumi, Georgia*

DO-03. On System Optimization for Magneto-Optic Switching: Material Considerations. *S. Kemmet¹, M. Mina¹ and R.J. Weber¹* *1. Electrical and Computer Engineering, Iowa State University, Ames, IA*

DO-04. Practical magneto-optic spatial light modulator with single magnetic domain pixels. *K. Iwasaki¹, H. Mochizuki¹, H. Umezawa¹ and M. Inoue²* *1. Research and Development Division, FDK CORPORATION, 2281 Washizu, Kosai-Shi, Shizuoka, Japan; 2. Toyohashi University of Technology, 1-1 Hibarigaoka, Tennpakucho, Toyohashi-shi, Aichi, Japan*

DO-05. Enhanced magneto-optics in magnetic nanostructures, magnetophotonic crystals and semiconductors. *A. Granovsky¹, E. Ganshina¹, N. Perov¹, A. Vinogradov², A. Orlov³, Y. Kalinin⁴, A. Khanikaev⁵ and M. Inoue⁵* *1. Faculty of Physics, Moscow State University, Moscow, Russian Federation; 2. Institute for Theoretical and Applied Electromagnetics, Moscow, Russian Federation; 3. State Research Institute for the Rare-Metal Industry, Moscow, Russian Federation; 4. Department of Solid State Physics, Voronezh State Technical University, Voronezh, Russian Federation; 5. Department of Electrical and Electronic Engineering, Toyohashi University of Technology, Toyohashi, Japan*

DO-06. Temperature properties of magneto-optic film and the non-destructive testing of a paramagnetic specimen. *J. Lee¹ and R. Wang²* *1. Department of Information and Communication Engineering, Chosun University, Gwangju, South Korea; 2. Department of Information and Communication Engineering, Graduate School of Chosun University, Gwangju, South Korea*

DO-07. Enhanced magneto-optical diffraction by gyrotropic gratings. *Y. Lu¹, M. Cho¹, J. Kim¹, G. Lee¹, Y. Lee¹ and J. Rhee²* *1. Quantum Photonic Science Research Center and BK21 Program Division of Advanced Research and Education in Physics, Hanyang University, Seoul, South Korea; 2. BK21 Physics Research Division and Department of Physics, Sungkyunkwan University, Suwon, South Korea*

DO-08. Surface plasmon resonance effects in the magneto-optical activity of Ag/Co/Ag trilayers. *E. Ferreira¹, X. Bendaña¹, J. González-Díaz¹, A. García-Martín¹, J. García-Martín¹, G. Armelles¹, A. Cebollada¹, D. Meneses² and E. Muñoz-Sandoval²* *1. Instituto de Microelectrónica de Madrid, IMM (CNM-CSIC), Tres Cantos, Spain; 2. Advanced Materials Department, IPICYT, San Luis Potosí, Mexico*

DO-09. Magneto-optical properties of wider gap magnetic semiconductor ZnMnTe and ZnMnSe films. *M. Imamura¹, A. Okada² and H. Higuchi¹ 1. Fukuoka Inst. of Tech., Fukuoka, Japan; 2. Mitsubishi Electric Corp., Amagasaki, Japan*

DO-10. Magnonic crystals-theory, experiment, parametric processes. *S.A. Nikitov¹, S. Bankov¹, Y. Filimonov¹, A. Kozhevnikov¹ and S. Vysotsky¹ 1. IRE, RAS, Moscow, Russian Federation*

DO-11. Enhanced magneto-optical activity in au/co/au nanodisks with localized surface plasmon resonances. *J.B. Gonzalez-Diaz¹, G. Armelles¹, A. García-Martín¹, A. Cebollada¹, J.M. García-Martín¹, B. Sepúlveda^{2,1}, M. Käll² and L. Balcells³ 1. Instituto de Microelectrónica de Madrid, IMM (CNM-CSIC), Tres Cantos, Spain; 2. Chalmers University of Technology, Göteborg, Sweden; 3. Institut de Ciència de Materials de Barcelona, Bellaterra, Spain*

DO-12. Magnetic inverse opals. *D. Hrabovsky¹, E. Taboada¹, M. Lopez², J. Fontcuberta¹, C. Lopez² and A. Roig¹ 1. Institut de Ciència de Materials de Barcelona (CMAB-CSIC), Bellaterra, Spain; 2. Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), Madrid, Spain*

DO-13. Controllability of growth-induced anisotropy of thin garnet films grown on (210)-oriented substrates. *S. Tkachuk¹, D. Bowen¹, C. Krafft² and I.D. Mayergoyz^{1,3} 1. Electrical and Computer Engineering, University of Maryland, College Park, MD; 2. Laboratory for Physical Sciences, College Park, MD; 3. UMIACS, University of Maryland, College Park, MD*

DO-14. Adjustable Faraday rotation by using one dimensional magnetophotonic crystals. *M. Hamidi¹, A. Bananej³, M. Tehrani^{1,2} and M. Ghanaat Shoar¹ 1. laser and plasma resurch institute, Shahid Beheshti University, Tehran, Iran; 2. physics department, Shahid Beheshti University, Tehran, Iran; 3. Laser and Optics Research School, Tehran, Iran*

DO-15. Optical Tamm states in 1D magnetophotonic crystals. *T. Goto¹, A. Baryshev^{1,4}, M. Inoue¹, A. Merzlikin², A. Vinogradov² and A. Granovsky³ 1. Toyohashi University of Technology, Toyohashi, Japan; 2. Institute for Theoretical and Applied Electromagnetics, Moscow, Russian Federation; 3. Moscow State University, Moscow, Russian Federation; 4. Ioffe Physico-Technical Institute, St. Petersburg, Russian Federation*

DO-16. Magneto-plasmonic nanostructures: a way to control surface plasmon excitation for Biosensor application. *D. Regatos¹, A. Calle², A. Cebollada², L. Lechuga¹ and A. Armelles² 1. Nanobiosensor and Molecular nanobiophysics Group, Research Center on Nanoscience and Nanotechnology (CIN2: CSIC-ICN), Bellaterra, Barcelona, Spain; 2. Microelectronics Institute of Madrid (IMM-CNM), Tres Cantos, Madrid, Spain*

DO-17. Layered bismuth iron garnet films for magneto-optical applications. *M. Kucera¹ and R. Gerber² 1. Faculty Math. & Physics, Charles University, Prague, Czech Republic; 2. School of Sciences, Salford University, Salford, United Kingdom*

**TUESDAY
AFTERNOON
2:30**

POLIVALENTE

**Session DP
SPIN TORQUE OSCILLATORS - II
(POSTER SESSION)
Jean-Eric Wegrowe, Chair**

DP-01. Thermal properties of Spin Torque Oscillators: Singularity in Effective Energy. *P.B. Visscher¹ and S. Wang¹ 1. Department of Physics and MINT Center, University of Alabama, Tuscaloosa, AL*

DP-02. Spin torque induced RF-oscillations of the magnetic end domains in CoFeB/MgO/CoFeB nanopillars under subthreshold currents. *S. Cornelissen^{1,3}, M. van Kampen¹, G. Hrkac², T. Schreffl² and L. Lagae¹ 1. NEXTNS, IMEC, Heverlee(Leuven), Belgium; 2. Department of Engineering Materials, University of Sheffield, Sheffield, United Kingdom; 3. EHSAT, K.U.Leuven, Leuven, Belgium*

DP-03. Experimental Study of Current-Driven Spin-Wave Excitations in GMR Nanopillars. *Q. Mistral¹, J. Kim¹, T. Devolder¹, P. Crozat¹, C. Chappert¹, J. Katine², M. Carey² and K. Ito³ 1. Institut d'Electronique Fondamentale, CNRS / Univ. Paris Sud, Orsay, France; 2. Hitachi Global Storage Technologies, San Jose, CA; 3. Advanced Research Laboratory, Hitachi, Tokyo, Japan*

DP-04. Influence Of The Spin Current Polarization And Direction On The Current-Excited Spin Waves In A Nanopillar Spin Valve: A Micromagnetic Study. *A.V. Khvalkovskiy^{1,2}, B. Georges¹, J. Grollier¹, Y.V. Gorbunov³, K.A. Zvezdin², V. Cros¹, H. Jaffres¹ and A. Fert¹ 1. Unité Mixte de Physique CNRS/Thales, Palaiseau, France; 2. A.M. Prokhorov General Physics Institute of RAS, Moscow, Russian Federation; 3. Institute of Microtechnology – Spin MT Ltd., Moscow, Russian Federation*

DP-05. Angular dependence of generation linewidth of in-plane-magnetized anisotropic spin-torque oscillator. *V. Tyberkevych¹ and A. Slavin¹ 1. Department of Physics, Oakland University, Rochester, MI*

DP-06. Mutual phase-locking of two spin-torque oscillators: Influence of time delay of a coupling signal. *O. Prokopenko¹, V. Tyberkevych² and A. Slavin² 1. Faculty of Radiophysics, Kiev National Taras Shevchenko University, Kiev, Ukraine; 2. Department of Physics, Oakland University, Rochester, MI*

DP-07. Influence of the Demagnetizing Field in Spin Dynamics with A Perpendicular-to-Plane Polarizer. *C. Jui-Hang¹ and C. Ching-Ray¹ 1. Department of Physics, National Taiwan University, Taipei, Taiwan*

DP-08. Investigation of spin-wave radiation and current controlled three-magnon-scattering in spin-torque nanocontact devices. *H. Schultheiss¹, X. Janssens², M. van Kampen², S. Cornelissen², F. Ciubotaru¹, A. Laraoui¹, B. Leven¹, A.N. Slavin³, L. Lagae² and B. Hillebrands¹ 1. Fachbereich Physik und Forschungsschwerpunkt MINAS, TU Kaiserslautern, Kaiserslautern, Germany; 2. IMEC, Leuven, Belgium; 3. Oakland University, Rochester, MI*

DP-09. Mutual phase-locking in high frequency microwave nanooscillators as function of field angle. G. Hrkac¹, T. Schrefl¹, S. Bance¹, A. Goncharov¹, J. Dean¹, D. Allwood¹, D. Suess² and J. Fidler². *1. University of Sheffield, Sheffield, United Kingdom; 2. Vienna University of Technology, Vienna, Austria*

DP-10. Non-stationary analysis of large magnetization dynamics in nanoscale spin-valves. G. Finocchio¹, L. Torres², M. Carpentieri¹, G. Consolo¹ and B. Azzerboni¹. *1. University of Messina, Messina, Italy; 2. Universidad de Salamanca, Salamanca, Spain*

DP-11. Magnetic Vortex Oscillators driven by Spin-Polarized Current and Perpendicular Anisotropy at Zero-Field. V. Puliafito¹, B. Azzerboni¹, G. Consolo¹, G. Finocchio¹, L. Torres² and L. Lopez-Diaz². *1. Dipartimento di Fisica della Materia e Tecnologie Fisiche Avanzate, University of Messina, Messina, Italy; 2. Departamento de Fisica Aplicada, University of Salamanca, Salamanca, Spain*

DP-12. Linear and Nonlinear Frequency Modulation of Nanocontact Spin-Transfer Oscillators: A Micromagnetic Study. G. Consolo¹, V. Puliafito¹, L. Lopez-Diaz² and B. Azzerboni¹. *1. Dipartimento di Fisica della Materia e Tecnologie Fisiche Avanzate, University of Messina, Messina, Italy; 2. Departamento de Fisica Aplicada, University of Salamanca, Salamanca, Spain*

DP-13. Intrinsic Capacitance Effect on Microwave Power Spectra of Spin-Torque Oscillator with Thermal Noise. B. Guan¹, Y. Zhou², F. Shin¹ and J. Åkerman². *1. Applied Physics, The Hong Kong Polytechnic University, Hong Kong, China; 2. Institute of Microelectronics and Information Technology, Royal Institute of Technology, Stockholm-Kista, Sweden*

DP-14. Spin torque oscillator phase locking to a noisy alternating current. E. Iacocca¹, Y. Zhou¹, J. Persson¹ and . Johan¹. *1. Institute of Microelectronics and Information Technology, Royal Institute of Technology, Stockholm-Kista, Sweden*

DP-15. Point contact Spin Torque Oscillators at high magnetic fields: Non-monotonic field dependence of oscillation threshold current. S. Bonetti¹, J. Garcia¹, J. Persson¹, F.B. Mancoff² and J. Åkerman¹. *1. Microelectronics and Applied Physics, Royal Institute of Technology (KTH), Kista-Stockholm, Sweden; 2. Technology Solutions Organization, Freescale Semiconductor Inc., Chandler, AZ*

DP-16. Time-dependent locking between a spin torque oscillator and an ac current. Y. Zhou¹, J. Persson¹ and J. Åkerman¹. *1. Institute of Microelectronics and Information Technology, Royal Institute of Technology, Stockholm, Sweden*

DQ-02. Stochastic resonance in phase synchronization of auditory steady state responses in MEG. K. Tanaka¹, M. Kawakatsu² and I. Nemoto^{1,2}. *1. Research Center for Advanced Technologies, Tokyo Denki University, Inzai, Chiba, Japan; 2. School of Information Environment, Tokyo Denki University, Inzai, Chiba, Japan*

DQ-03. Preparation, Characterization and Testing of Magnetic Carriers for Arsenic Removal from Water. A.M. Estevez¹, J.M. Rodriguez¹, A. Alvaro¹ and P.A. Augusto². *1. Department of Chemical Engineering, University of Salamanca, Salamanca, Castilla y Leon, Spain; 2. DEQ, Faculdade de Engenharia da Universidade do Porto, Porto, Portugal*

DQ-04. Synthesis of superparamagnetic nanoparticles by non conventional routes and their feasible application as contrast agents. R. Costo¹, A.G. Roca¹, M. Morales¹ and S. Veintemillas-Verdaguer¹. *1. Materiales Particulados, Instituto de Ciencia de Materiales de Madrid, Madrid, Madrid, Spain*

DQ-05. Magnetic properties of iron oxyhydroxynitrate nanoparticles. N.J. Silva¹, V.S. Amaral², L.D. Carlos², A. Millán¹, F. Palacio¹, B. Rodríguez-González³, L.M. Liz-Marzán³, T. Berquó⁴, F. Fauth⁵ and V. de Zea Bermudez⁶. *1. Fisica de la Materia Condensada, Instituto de Ciencia de Materiales de Aragón, CSIC/Universidad de Zaragoza, Zaragoza, Spain; 2. Departamento de Física and CICECO, Universidade de Aveiro, Aveiro, Portugal; 3. Departamento de Química Física, Universidad de Vigo, Vigo, Spain; 4. Institute for Rock Magnetism, University of Minnesota, Minneapolis, MN; 5. ILLS, BM16-ESRF, Grenoble, France; 6. Departamento de Química, Universidade de Trás-os-Montes e Alto Douro and CQ-VR, Vila Real, Portugal*

DQ-06. Biosorption of Cu(II) ions by magnetically labeled yeast. S.V. Gorobets¹, V.V. Lizunov¹ and I.V. Dem'yanenko¹. *1. National Technical University of Ukraine "Kyiv Polytechnic Institute", Kyiv, Ukraine*

DQ-07. COATING of cobalt ferrite nanoparticles with silica for an in-vitro gmr biosensor agent. S. Tang¹, S. Bae¹ and W. Lee². *1. Electrical and Computer Engineering, Biomagnetics Laboratory (BML), National University of Singapore, Singapore 117576, Singapore, Singapore; 2. Dept of Physics, Sookmyung Women's University, Seoul 140-742, Seoul, Seoul, South Korea*

DQ-08. Effect of Metallic-coating Thickness of Thermosensitive Magnetic Powder for Cancer Therapy. T. Takura¹, F. Sato¹, H. Matsuki¹ and T. Sato². *1. Dept. of Electrical and Communication Engineering, Graduate School of Engineering, Tohoku University, Sendai, Miyagi, Japan; 2. NEC Tokin Corp., Sendai, Japan*

DQ-09. Fe Oxide Nanoparticles produced by laser pyrolysis for biomedical applications. V. Bouzas¹, R. Costo², M. García¹, M. Morales² and S. Veintemillas-Verdaguer². *1. Dpt. Material Science, Universidad Complutense de Madrid, Madrid, Madrid, Spain; 2. Institute of Materials Science, CSIC, Madrid, Madrid, Spain*

DQ-10. Magnetic properties and potential biomedical applications of CM-CL-SPIONs. M. Lin¹, J. Gu¹, T. Veres³, J. Dobson¹, H. Lee², M. Muhammed⁴ and D. Kim¹. *1. Institute of Science and Technology in Medicine, Keele University, Stoke-on-Trent, United Kingdom; 2. Department of Materials Science and Engineering, Myongji University, Kyunggi-do, South Korea; 3. Industrial Materials Institute, National Research Council Canada, Boucherville, QC, Canada; 4. Materials Chemistry Division, Royal Institute of Technology, Stockholm, Sweden*

TUESDAY
AFTERNOON
2:30

POLIVALENTE

Session DQ LIFE SCIENCE AND APPLICATIONS-I (POSTER SESSION)

Weilie Zhou, Chair

DQ-01. Estimation method on multiple sources of MEG based on columnar structure of the cerebral cortex. (Invited) H. Fukuda¹, M. Odagaki¹, O. Hiwaki¹, A. Kodabashi² and T. Fujimoto². *1. Graduate School of Information Sciences, Hiroshima City University, Hiroshima, Japan; 2. Fujimoto Hayasuzu Hospital, Miyakonojo, Japan*

TUESDAY
AFTERNOON
2:30

POLIVALENTE

Session DR
MAGNETIC ELEMENTS AND ANTIDOT ARRAYS
(POSTER SESSION)

Feng Luo, Chair

- DR-01. Controlling vortex chirality in magnetic submicron dots by modulating the magnetic properties in lateral direction.** Z. Zhong¹, H. Zhang¹, X. Tang¹, Y. Jing¹, L. Jia¹ and L. Zhang¹. *State Key Laboratory of Electronic Thin Films and Integrated Devices, University of Electronic Science and Technology of China, Chengdu, Sichuan, China*
- DR-02. Helical states in multilayer nanomagnets.** V. Mironov¹, A. Fraerman¹, B. Gribkov¹, S. Gusev¹, S. Vdovichev¹, B. Hjorvarsson² and H. Zabel³. *1. Institute for physics of microstructures RAS, Nizhny Novgorod, Russian Federation; 2. Uppsala University, Uppsala, Sweden; 3. Ruhr-University, Bochum, Germany*
- DR-03. Double vortex interaction of micron-sized elliptical Py element studied by real-time Kerr microscopy.** B. Hong¹, J. Bland¹ and J. Jeong^{1,2}. *1. Cavendish Laboratory, Cambridge University, Cambridge, United Kingdom; 2. Department of Materials Science and Engineering, Chungnam National University, Daejeon, South Korea*
- DR-04. Evolution of mixed states composed of vortex cores and anti-vortex cores in different helicities under external field.** Z. Wei¹, M. Lai¹, C. Lee¹, Z. San¹, Y. Hsieh¹ and T. Ho¹. *1. National Tsing Hua University, Hsinchu, Taiwan*
- DR-05. Effect on the dipole-dipole interaction between adjacent dots in Ni-Fe elliptical dot arrays.** Y. Endo¹, H. Fujimoto², Y. Kawamura², R. Nakatani^{2,3} and M. Yamamoto². *1. Dept. of Electrical and Communication Engineering, Tohoku University, Sendai, Japan; 2. Dept. of Materials Science and Engineering, Osaka University, Suita, Japan; 3. Center for Atomic and Molecular Technologies, Osaka University, Suita, Japan*
- DR-06. The effect of dipolar interaction on the magnetization reversal of nano-patterned permalloy dots array.** Y. Tsai¹, C. Chang¹, J. Wang¹, J. Wu¹ and L. Horng¹. *1. Taiwan SPIN Research Center, National Changhua University of Education, Changhua, Taiwan*
- DR-07. Interaction in soft magnetic bilayers nanoscale arrays.** J.E. Davies², L.H. Bennett^{1,2}, E. Della Torre^{1,2}, B.C. Choi³, S.N. Piramanayagam⁴ and E. Girgis⁵. *1. George Washington University, Washington, DC; 2. National Institute of Standards and Technology, Gaithersburg, MD; 3. University of Victoria, Victoria, BC, Canada; 4. Data Storage Institute, Singapore, 117 608, Singapore; 5. National Research Center, Dokki, Giza, Egypt*
- DR-08. Magnetic imaging and angle-resolved magnetoresistance behaviour of micropatterned films containing Co antidots.** E. Celasco^{1,2}, P. Martino¹, A. Chiolerio¹, F. Celegato³ and P. Allia¹. *1. Physics, Polytechnic of Turin, Turin, Italy; 2. Physics, Materials and Microsystems Laboratory (χ-lab)- LATEMAR Unit, Chivasso (TO), Italy; 3. INRIM, Torino, Italy*

DR-09. Analysis of the nucleation-propagation sequence in the magnetization reversal of antidot arrays. F. García-Sánchez¹, E. Paz¹, O. Fesenko-Chubykalo¹, F. Palomares¹, J. González¹, F. Cebollada², J. Haba², R. Yanes¹ and U. Atxitia¹. *1. Instituto de Ciencia de Materiales de Madrid, CSIC, 28049 Cantoblanco, Madrid, Spain; 2. Física Aplicada a las Tec.de la Inf., Univ. Politécnica de Madrid, 28031 Madrid, Spain*

DR-10. Magnetic behaviour of Ni antidot arrays on alumina nanoporous membranes. P. Prieto¹, A.J. Chaves-Neto³, K.R. Pirola², M. Knobel³ and J.M. Sanz¹. *1. Física Aplicada, Universidad Autónoma de Madrid, Madrid, Spain; 2. Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain; 3. Instituto de Física "Gleb Wataghin", Universidad Estadual de Campinas, Campinas, Brazil*

DR-11. TAILORING magnetization reversal mode and switching field of magnetic nanostructure with perpendicular anisotropy. M. Rahman¹, N.N. Shams¹, Y. Wu¹ and C. Lai¹. *1. Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan*

DR-12. Property variation in coupled permalloy nanostructures. A.O. Adeyeye¹, S. Jain¹ and N. Singh². *1. Electrical and Computer Engineering, National University of Singapore, Singapore, Singapore; 2. Institute of Microelectronics, Singapore, Singapore*

TUESDAY
AFTERNOON
2:30

POLIVALENTE

Session DS
MICROWAVE SYSTEMS
(POSTER SESSION)
Vasil Tyberkevych, Chair

DS-01. Double Ferromagnetic Resonance Absorption Of Non-Saturated States In Arrays of Bi-Stable Magnetic Nanowires. J. De La Torre Medina¹, J. Olais-Govea², A. Encinas² and L. Piraux¹. *1. Université Catholique de Louvain, Louvain-la-Neuve, Belgium; 2. Instituto de Física, San Luis Potosí, Mexico*

DS-02. Soft magnetic properties and high frequency characteristics in FeCoSi/native-oxide multilayer films. H. Zuo¹, S. Ge¹, Z. Wang¹, Y. Xiao¹ and D. Yao¹. *1. Key Laboratory for Magnetism and Magnetic Materials of Ministry of Education, Lanzhou University, Lanzhou, China*

DS-03. Excellent low loss performance of microwave permeability in high resistive CoFeHfO films by thermal annealing. K. Dong Young¹, Y. Seok Soo¹, R. B. Parvatheeswara², K. Cheol Gi² and T. Migaku³. *1. Department of Physics, Andong National University, Andong, South Korea; 2. School of Nano-Science and Engineering, Chungnam National University, Daejeon, South Korea; 3. Electronic Engineering, Tohoku University, Sendai, Japan*

DS-04. MAGNETOIMPEDANCE EFFECT IN SANDWICHED AND MULTILAYERED AMORPHOUS FILMS: SIMULATION AND EXPERIMENTS. *M.A. Corrêa¹, F. Bohn², A. Viegas³, A. de Andrade⁵ and R. Sommer⁴* *1. Centro de Ciências Exatas e Tecnológicas, Universidade Federal do Pampa, Caçapava do Sul, Rio Grande do Sul, Brazil; 2. Departamento de Física, Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil; 3. Departamento de Física, Universidade Federal de Santa Catarina, Santa Maria, Santa Catarina, Brazil; 4. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Rio de Janeiro, Brazil; 5. Universidade Federal de Santa Maria, Frederico Westphalen, Rio Grande do Sul, Brazil*

DS-05. Complex impedance and capacitance spectra characterizations of MgO-based MTJs with/without Mg doping. *J. Huang^{1,2}, C. Hsu^{1,2}, W. Chen¹, S. Chen³ and C. Liu³* *1. Physics, National Cheng-Kung University, Tainan, Taiwan; 2. Institute of Innovations and Advanced Studies, National Cheng-Kung University, Tainan, Taiwan; 3. Materials Science and Engineering, National Cheng-Kung University, Tainan, Taiwan*

DS-06. A modulated microwave absorption study of FeNbO₄ *G. Alvarez¹, R. Font², J. Portelles², R. Zamorano³ and R. Valenzuela¹* *1. Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, México City, D.F., México; 2. Física Aplicada, Universidad de la Habana, Havana, Havana, Cuba; 3. Ciencia de los Materiales, Instituto Politécnico Nacional, México City, D.F., México*

DS-07. IrMn/CoFe-SiO₂/IrMn exchange coupled nanostructure for high frequency applications. *N.N. Shams¹, M. Rahman¹, Y. Wu¹ and C. Lai¹* *1. Materials Science and Engineering, National Tsing-Hua University, Hsinchu, Taiwan*

DS-08. Permeability of ferromagnetic microwires composites/metamaterials and potential applications. *L. Liu¹, L. Kong¹, G. Lin¹ and S. Matitsine¹* *1. Temasek Lab, National University of Singapore, Singapore, Singapore*

DS-09. Microwave permeability of amorphous FeCoSiB thin films on flexible substrates. *M. Han¹, Y. Ou¹, L. Deng¹, J. Xie¹ and H. Lu¹* *1. State Key Laboratory of Electronic Thin Films and Integrated Devices, University of Electronic Science and Technology of China, Chengdu, Sichuan, China*

DS-10. Magnetic damping in exchange-coupled IrMn/ CoFe multilayers for microwave applications. *R. Jiang¹, C. Lai¹ and J. Lin²* *1. Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan; 2. Centre for Condensed Matter Sciences, National Taiwan University, Taipei, Taiwan*

DT-02. Development of anisotropic NdFeB bonded magnet MAGFINE with high heat resistance for automobile use. *K. Noguchi¹, C. Mishima¹, H. Matsuoka¹ and Y. Honkura¹* *1. Aichi Steel Corporation, Tokai-shi, Aichi-ken, Japan*

DT-03. Effects of conventional HDDR process and the additions of Co and Zr on anisotropy of HDDR PrFeB-type magnetic materials. *J. Han¹, C. Wang¹, H. Du¹, H. Chen¹ and Y. Yang¹* *1. School of Physics, Peking University, Beijing, China*

DT-04. Magnetic properties and structure for bonded magnet using Dy-F coated NdFeB powder. *M. Komuro¹ and S. Yuichi¹* *1. Energy and Environment Laboratory, Advanced Research Laboratory, Hitachi, Ibaraki, Japan*

DT-05. Effect of grain size and hot-deformation temperature on texture in die-upset Nd-Fe-B magnet. *H. Kwon¹ and J. Lee¹* *1. Materials Science and Engineering, Pukyong National University, Busan, South Korea*

DT-06. Boron enriched stoichiometric melt spun RE₂(Fe,Co)₁₄B-based alloys with enhanced coercivity. *I. Betancourt^{1,2}, T. Schrefl¹ and H. Davies¹* *1. Department of Engineering Materials, University of Sheffield, Sheffield, South Yorkshire, United Kingdom; 2. Departamento de Materiales Metálicos y Cerámicos, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, México, D.F. 04510, México*

DT-07. The copper, titanium and carbon influence on properties of permanent magnets based on FeNdB alloy. *G.P. Brekharya¹, V. Vystavkina² and K. Elena¹* *1. Solid State Physics, Dneprodzerzhinsk Technical State University, Dneprodzerzhinsk, Ukraine; 2. Materials Science, Zaporozhye State University, Zaporozhye, Ukraine*

DT-08. Effect of heat treatment on the magnetic property and microstructure of sintered Nd-Fe-B magnets. *W. Li¹, T. Ohkubo^{1,2} and K. Hono^{1,2}* *1. National Institute for Materials Science, Tsukuba, Japan; 2. CREST, JST, Japan*

DT-09. Field-induced coercivity enhancement phenomena in sintered Nd-Fe-B magnets. *H. Kato^{1,2}, T. Akiya² and K. Koyama³* *1. Department of Applied Mathematics and Physics, Yamagata University, Yonezawa, Japan; 2. New Industry Creation Hatchery Center, Tohoku University, Sendai, Japan; 3. Institute for Materials Research, Tohoku University, Sendai, Japan*

DT-10. Small angle neutron scattering study of interface nanostructure in sintered Nd-Fe-B magnets. *T. Akiya¹, H. Kato^{1,2}, M. Takeda³, J. Suzuki³, D. Yamaguchi⁴, S. Koizumi⁴, M. Sagawa⁵ and K. Koyama⁶* *1. New Industry Creation Hatchery Center, Tohoku Univ., Sendai, Miyagi, Japan; 2. Department of Applied Mathematics and Physics, Yamagata Univ., Yonezawa, Yamagata, Japan; 3. Quantum Beam Science Directorate, Japan Atomic Energy Agency (JAEA), Tokai-mura, Naka-gun, Ibaraki, Japan; 4. Advances Science Research Center, Japan Atomic Energy Agency (JAEA), Tokai-mura, Naka-gun, Ibaraki, Japan; 5. Intermetallics Co., Ltd., Kyoto, Japan; 6. Institute for Materials Research, Tohoku University, Sendai, Miyagi, Japan*

DT-11. Reduction of sensitivity to sintering temperature for Nd-Fe-B magnets through co-doping Zr and Nb. *M. Yan¹, X. Cui¹, L. Yu¹ and T. Ma¹* *1. Department of Materials Science and Engineering, Zhejiang University, Hangzhou, China*

TUESDAY
AFTERNOON

**Session DU
PERMANENT MAGNET MATERIALS - APPLICATIONS II
(POSTER SESSION)
Tom Woodcock, Chair**

DU-01. Multi-tooth Flux Switching PM Brushless ac Machines for High Torque Direct-Drive Applications. *Z. Zhu¹, J. Chen¹, D. Howe¹, S. Iwasaki² and R. Deodhar² 1. University of Sheffield, Sheffield, United Kingdom; 2. IMRA UK Research Center, University of Sussex, Brighton, United Kingdom*

DU-02. Optimum Design of Transverse Flux Linear Motor for Weight Reduction and Improvement Thrust Force Using Response Surface Methodology. *D. Hong¹, B. Woo¹ and D. Kang¹ 1. Korea Electrotechnology Research Institute, Changwon, South Korea*

DU-03. 2D analytical calculation of the no-load induced EMF in an axial flux slotted permanent magnet machine. *J. Pérez¹ and F. Frechoso^{1,2} 1. Electrical Engineering, Universidad de Valladolid, Valladolid, Spain; 2. Member, IEEE, Valladolid, Spain*

DU-04. Modeling permanent magnet axial flux machine with Lie's symmetries. *L.T. Loureiro¹, J.R. Zabadal², A.F. Flores¹ and R.P. Homrich¹ 1. Electrical Engineering, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil; 2. Nuclear Engineering, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil*

DU-05. Optimal Design of an SPM Motor Using Taguchi Method and Genetic Algorithms. *C. Hwang¹, L. Lyu¹, P. Li¹ and C. Liu² 1. EE, Feng Chia University, Seatwen, Taichung, Taiwan; 2. EE, National Sun Yat-sen University, Kaohsiung, Taiwan*

DU-06. On the Material and Temperature Impacts of Interior Permanent Magnet Machine for Electric Vehicle Applications. *A. Wang¹, H. Li¹ and C. Liu² 1. Electrical Engineering, North China Electric power university, Baoding, Hebei, China; 2. Electrical Engineering, National Sun Yat-Sen University, Kaohsiung, Taiwan*

DU-07. Fabrication and properties of FePt thick films for micro-machine application. *P. Jang¹, B. Lee¹, K. Rhie² and S. Choi² 1. Div. of Applied Science, Cheongju University, Cheongju, Chungcheongbuk-do, South Korea; 2. Department of display, semiconductor and physics, Korea University, Chochiwon, Chungcheongnam-do, South Korea*

DU-08. Optimum Design of 60 W Longitudinal Flux Linear Motor for Weight Reduction and Improvement Performance Using DOE. *D. Hong¹, B. Woo¹ and D. Kang¹ 1. Korea Electrotechnology Research Institute, Changwon, South Korea*

DU-09. Optimal Design of a Small PM Wind Synchronous Generator for Wide Range of Winds Speed. *B. Ebrahimi¹, J. Faiz¹, M. Rajabi Sebdani¹ and M.A. Khan² 1. Department of Electrical and Computer Engineering, University of Tehran, University of Tehran, Tehran, Iran; 2. Department of Electrical Engineering, University of Cape Town, Cape Town, South Africa*

DU-10. Analytical analysis of magnetic field and back electromotive force calculation of an axial-flux permanent magnet synchronous generator with coreless stator. *P. Vrtič¹, P. Pišek¹, T. Marčič¹, M. Hadziselimović^{1,2} and B. Stumberger^{1,2} 1. TECES, Development centre for electrical machines, Maribor, Slovenia; 2. Faculty of Electrical Engineering and Computer Science, University of Maribor, Maribor, Slovenia*

**TUESDAY
AFTERNOON
2:30**

POLIVALENTE

**Session DV
MANGANITES
(POSTER SESSION)
Gervasi Herranz, Chair**

DV-01. Theoretical and experimental studies of structural characteristics, magnetic response and electronic properties of Sr_{1-x}FeMnO₆ double cubic Perovskite. *J.A. Rodríguez¹, D.A. Landinez-Tellez¹, R. Cardona¹, F.E. Fajardo¹ and J. Roa-Rojas¹ 1. Physics Dept., Universidad Nacional de Colombia, Bogotá, D. C., Colombia*

DV-02. Local probe studies on Pr_{1-x}Ca_xMnO₃ system. *A.M. Lopes^{1,2}, T.M. Mendonça^{1,2}, J.S. Amaral³, A.M. Pereira¹, P.B. Tavares⁴, Y. Tomioka⁵, Y. Tokura⁶, J.G. Correia^{7,2}, V.S. Amaral³ and J.P. Araújo¹ 1. Department of Physics and IFIMUP, Univ. of Porto, Porto, Portugal; 2. EP, CERN, Geneva, Switzerland; 3. Department of Physics and CICECO, Univ. of Aveiro, Aveiro, Portugal; 4. Department of chemistry and CQ-VR, Univ. of Tras-os-Montes e Alto Douro, Vila Real, Portugal; 5. CERC, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan; 6. Department of Applied Physics, Univ. of Tokyo, Tokyo, Japan; 7. Instituto Tecnológico Nuclear, Sacavém, Portugal*

DV-03. Complex magnetic behaviour in anion deficient manganite superstructures *R. Cortés-Gil^{1,2}, J. M. Alonso^{2,3}, A. Hernando^{2,4}, M. L. Ruiz-González¹, M. García-Hernández³, M. Vallet-Regí^{2,5}, J. M. González-Calbet^{1,2,*} 1Departamento de Química Inorgánica, Facultad de Químicas, Universidad Complutense, 28040-Madrid, Spain 2Instituto de Magnetismo Aplicado, UCM-CSIC-RENFE, Las Rozas, P.O. Box 155, 28230-Madrid, Spain 3Instituto de Ciencia de Materiales, CSIC, Sor Juana Inés de la Cruz s/n, 28049-Madrid, Spain 4Departamento de Física de Materiales, Facultad de Físicas, Universidad Complutense, 28040-Madrid, Spain 5Departamento de Química Inorgánica y Bioinorgánica, Facultad de Farmacia, Universidad Complutense, 28040- Madrid, Spain. J.M. González-Calbet¹ 1. Química Inorgánica, UCM, Madrid, Spain*

DV-04. Anisotropic magnetoresistance in ferromagnetic manganites. *M. Granada*¹, J. Rojas Sánchez¹, L.B. Steren¹, J.D. Fuhr¹ and B. Alascio¹. *Centro Atómico Bariloche (Comisión Nacional de Energía Atómica) and CONICET, San Carlos de Bariloche, Río Negro, Argentina*

DV-05. Comparative study of magnetic ordering in bulk and nanometer-sized $\text{La}_{0.4}\text{Ca}_{0.6}\text{MnO}_3$ manganite. *E. Rozenberg*¹, M. Auslender¹, A.I. Shames¹, I. Felner², E. Sominski³, A. Gedanken³, A. Pestun⁴ and Y. Mukovskii⁴. *1. Physics, BGU of the Negev, Beer-Sheva, Israel; 2. Physics, The Hebrew University, Jerusalem, Israel; 3. Chemistry, Bar-Ilan University, Ramat-Gan, Israel; 4. Moscow Steel and Alloys Institute, Moscow, Russian Federation*

DV-06. EMR probing of magnetic ordering in $\text{Pr}_{1-x}\text{Sr}_x\text{MnO}_3$ ($x=0.22, 0.24, 0.26$) manganite single crystals. *A.I. Shames*¹, E. Rozenberg¹, Y.M. Mukovskii² and G. Gorodetsky¹. *1. Physics, Ben Gurion University of the Negev, Beer-Sheva, Israel; 2. Moscow Steel and Alloys Institute, Moscow, Russian Federation*

DV-07. Magnetic and magnetoresistive properties of $\text{Pr}_{1-x}\text{Ca}_x\text{CoO}_3$ ($x=0.3, 0.5$) cobaltites. *I.G. Deac*¹, R. Tetea¹, D. Andreica^{1,2} and E. Burzo¹. *1. Physics, Universitatea Babes-Bolyai, Cluj-Napoca, Romania; 2. Laboratory for Muon-Spin Spectroscopy, Paul Scherrer Institut, Villigen, Switzerland*

DV-08. Magnetism of LCMO/YBCO thinfilm epitaxial heterostructures. *N.M. Nemes*^{1,3}, M. García-Hernández¹, Z. Szatmári², T. Fehér², F. Simon², J. García-Barriocanal³, F.Y. Bruno³, C. Leon³, C. Miller³, Z. Sefrioui³, C. Visani³ and J. Santamaría³. *1. Instituto de Ciencia de Materiales de Madrid, Consejo Superior de Investigaciones Científicas, Madrid, Spain; 2. Institute of Physics, Budapest University of Technology and Economics, Budapest, Hungary; 3. GFMC, Dpto. Física Aplicada III, Universidad Complutense de Madrid, Madrid, Spain*

DV-09. In-situ strain effect on extrinsic electrical transport and magnetotransport in $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ films. *R. Gangineni*¹, L. Schultz¹, I. Mönch¹ and K. Dörr¹. *Institute for Metallic Materials, Leibniz Institute for Solid State and Materials Research Dresden, Dresden, Saxony, Germany*

DV-10. Effect of Cr Doping on the Magnetic Properties of $\text{La}_{0.3}\text{Ca}_{0.7}\text{MnO}_3$ *L.E. Wenger*¹, G.M. Tsou¹, R. Suryanarayanan² and T. Sudyoadsuk³. *1. Department of Physics, University of Alabama at Birmingham, Birmingham, AL; 2. Laboratoire de Physico-Chimie de l'Etat Solide, CNRS, Université Paris-Sud, Orsay, France; 3. Department of Chemistry, Ubon Ratchathani University, Ubon Ratchathani, Thailand*

DV-11. 1/f noise study of electron transport in $\text{La}_{0.82}\text{Ca}_{0.18}\text{MnO}_3$ single crystals. *X. Wu*^{1,2}, G. Jung², B. Dolgin², V. Markovich², Y. Yuzhelevski², M. Belogolovskii^{3,4}, Y.M. Mukovskii⁵, K. Suzuki¹ and G. Gorodetsky². *1. Materials Engineering, Monash University, Clayton, VIC, Australia; 2. Physics, Ben Gurion University, Beer Sheva, Israel; 3. Donetsk Physical and Technical Institute, National Academy of Sciences of Ukraine, Donetsk, Ukraine; 4. Scientific and Industrial Concern 'Nauka', Kyiv, Ukraine; 5. Moscow State Steel and Alloys Institute, Moscow, Russian Federation*

DV-12. Effect of substrate orientation on magnetic anisotropy and 1/f noise in $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ thin films. *L. Mechin*¹, P. Perna^{1,2}, M. Saib¹, S. Flament¹, C. Barone^{1,3}, D. Fadil¹ and J. Routoure¹. *GREYC-ENSICAEN, CNRS, Caen, France; 2. DiMSAT, University of Cassino, Cassino, Italy; 3. Dipartimento di Fisica "E.R. Caianiello", University of Salerno, Salerno, Italy*

DV-13. Room temperature giant magnetoimpedance in $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$. *M. Ramanathan*¹. *Department of Physics, National University of Singapore, Singapore, Singapore*

DV-14. Electroresistance in mixed valence manganites. *N. Biskup*¹, A. de Andrés¹ and M. Garcia Hernandez¹. *ICMM, Madrid, Spain*

DV-15. Impedance spectroscopy of magnetoresistive manganite films exhibiting electric-pulse-induced resistance switching. *T. Nakamura*¹, K. Homma¹, T. Yakushiji¹ and K. Tachibana¹. *Department of Electronic Science and Engineering, Kyoto University, Kyoto, Japan*

DV-16. Strain effect on MnO_6 octahedrons in the colossal magnetoresistance (CMR) films. *C. Wu*¹, H. Chou¹ and F. Yuan¹. *National Sun Yat-sen University, Kaohsiung, Taiwan*

DV-17. Pulsed current induced multi level resistivity switching in two magnetodielectrics: antiferromagnetic $\text{Nd}_{0.5}\text{Ca}_{0.5}\text{MnO}_3$ and ferromagnetic $\text{La}_2\text{NiMnO}_6$. *M. Ramanathan*¹. *Physics, National university of Singapore, Singapore, Singapore*

**TUESDAY
AFTERNOON
2:30**

POLIVALENTE

**Session DW
TRANSFORMERS AND INDUCTORS II
(POSTER SESSION)
Oriano Bottauscio, Chair**

DW-01. Design optimization of a non-contact rapid charging inductive power supply system for electric-driven vehicles based on finite-element electromagnetic field analyses. *Y. Kamiya*¹, Y. Daisho¹, R. Yokoyama¹ and S. Takahashi². *1. Graduate School of Environment and Energy Engineering, Waseda Univ., Tokyo, Japan; 2. Showa Aircraft, Tokyo, Japan*

DW-02. An Analytical Model of the Electromagnetic Efficiency of Litz-Wire Windings for Domestic Induction Heating Systems. *J. Acero*¹, R. Alonso², J.M. Burdío¹, L.A. Barragan¹ and J.I. Artigas¹. *1. Electronic Engineering and Communications, University of Zaragoza, Zaragoza, Spain; 2. Applied Physics, University of Zaragoza, Zaragoza, Spain*

DW-03. High Frequency Coaxial Transformer for DC/DC Converter Used in Solar PV Systems. *J. Lu*¹, X. Yang² and F. Dawson³. *1. School of Eng., Griffith University, Brisbane, QLD, Australia; 2. Province-Ministry Joint Key Laboratory of Electromagnetic Field and Electrical Apparatus Reliability, Hebei University of Technology, Tianjin., Hebei, China; 3. Department of Electrical and Computer Engineering, University of Toronto, Toronto, ON, Canada*

DW-04. Novel EU core variable inductor. *M. Xianmin*¹, L. Fengchun¹, W. Jianze² and J. Yanchao². *1. Department of Electrical and Electronics Engineering, DaLian University of Technology, DaLian, Liaoning, China; 2. School of Electrical Engineering and Automation, Harbin Institute of Technology, Harbin, Heilongjiang, China*

DW-05. Stability analysis of contact-less electrical energy detachable transformer. *H. Chen*¹, Q. Yang¹, J. Li¹, S. Yang¹ and S. Hou¹. *Hebei University of Technology, Tianjin, China*

DW-06. A Forced Vibration Analysis of Cable-type Power Transformer Winding by the Pseudospectral Method. J. Ha¹, H. Chung¹, S. Woo¹, P. Shin¹ and J. Lee¹ *1. Hongik University, Jochiwon, Chungnam 339-701, South Korea*

DW-07. Coupled three phase inductors for interleaved inverter switching. A. Knight¹, J. Ewanchuk¹ and J.C. Salmon¹ *1. Electrical and Computer Eng. University of Alberta, Edmonton, AB, Canada*

DW-08. A novel approach to extending the linearity range of displacement inductive sensor. M.S. Damjanovic¹, L. Zivanov¹, L. Nagy¹, S. Djuric¹ and B. Biberdzic¹ *1. Department of Electronics, Faculty of Technical Sciences, Novi Sad, Serbia*

DW-09. A New Technique for Measuring Ferrite Core Loss under DC Bias Conditions. C. Baguley¹, U.K. Madawala¹ and B. Carsten² *1. ECE, University of Auckland, Auckland, New Zealand; 2. Power Conversion Consulting and Research, Corvallis, OR*

**TUESDAY
AFTERNOON
6:30**

AUDITORIO A

10:30

EA-03. Time-Domain Studies of Nonlinear Magnetization Dynamics Excited by Spin Transfer Torque. (Invited) I. Krivorotov¹, N. Emley², J. Sankey², G. Finocchio³, L. Torres⁴, B. Azzerboni³, R. Buhrman² and D. Ralph² *1. Department of Physics and Astronomy, University of California, Irvine, Irvine, CA; 2. Cornell University, Ithaca, NY; 3. Dipartimento di Fisica della Materia e Tecnologie Fisiche Avanzate, University of Messina, Messina, Italy; 4. Departamento de Fisica Aplicada, Universidad de Salamanca, Salamanca, Spain*

11:00

EA-04. Current-driven vortex oscillations in metallic nanocontacts. (Invited) Q. Mistral¹, M. van Kampen², G. Hrkac³, J. Kim¹, T. Devolder¹, P. Crozat¹, C. Chappert¹ and L. Lagae² *1. Institut d'Electronique Fondamentale, CNRS / Univ. Paris Sud, Orsay, France; 2. IMEC, Leuven, Belgium; 3. Department of Engineering Materials, University of Sheffield, Sheffield, United Kingdom*

11:30

EA-05. Self-Torque Induced by Local Spin-Transfer Effect and Lateral Spin Diffusion in Magnetic Layers with Inhomogeneous Magnetization. (Invited) K. Lee¹ *1. Korea University, Seoul, South Korea*

12:00

EA-06. Spin Torque Influence on the High Frequency Magnetization Fluctuations in Magnetic Tunnel Junctions. (Invited) S. Petit¹, N. de Mestier¹, C. Thirion¹, U. Ebels¹, Y. Liu², M. Li², P. Wang² and C. Baraduc¹ *1. SPINTEC, CEA/CNRS, Grenoble, France; 2. Headway Technologies, Milpitas, CA*

**WEDNESDAY
MORNING
9:30**

AUDITORIO A

**Session EA
SYMPOSIUM ON SPIN TRANSFER AND DYNAMICS**

Thibaud Devolder, Chair

9:30

EA-01. Spin-torque oscillator in the presence of thermal noise. (Invited) A.N. Slavin¹, J. Kim² and V. Tiberkevich¹ *1. Department of Physics, Oakland University, Rochester, MI; 2. Institut d'Electronique Fondamentale, Universite Paris-Sud, Orsay, France*

10:00

EA-02. Frequency Pulling and Locking in RF Assisted Spin-Torque Switching. (Invited) S.H. Florez¹, J.A. Katine¹, M. Carey¹, O. Ozatay¹ and L. Folks¹ *1. Hitachi Global Storage Technologies, San Jose, CA*

**WEDNESDAY
MORNING
9:30**

MADRID

**Session EB
MOTOR AND ACTUATORS II**

Johannes Paulides, Chair

9:30

EB-01. Design considerations of tubular flux-switching permanent magnet machines. (Invited) J. Wang¹, W. Wang¹, K. Atallah¹ and D. Howe¹ *1. Electronic and Electrical Engineering, University of Sheffield, Sheffield, United Kingdom*

10:00

EB-02. Linear induction motors with modular winding primaries and wound rotor secondaries. *J. Eastham*¹, *T. Cox*^{1,2} and *J. Proverbs*² *1. The University of Bath, Bath, United Kingdom; 2. Force Engineering, Shepshed, United Kingdom*

10:15

EB-03. Magnetic Actuator Design using Level Set based Topology Optimization. *S. Park*¹, *S. Min*¹, *S. Yamasaki*², *S. Nishiwaki*² and *J. Yoo*³ *1. Mechanical Engineering, Hanyang University, Seoul, South Korea; 2. Aeronautics and Astronautics, Kyoto University, Kyoto, Japan; 3. Mechanical Engineering, Yonsei University, Seoul, South Korea*

10:30

EB-04. Comparson of numerical and analytical simulation of saturated zig-zag flux in induction machines. *A. Binder*¹, *T. Knopik*¹ and *R. Hagen*¹ *1. Institute for Electrical Energy Conversion, Technische Universität Darmstadt, Darmstadt, Germany*

10:45

EB-05. Newly structured double excited 2-DOF motor for security camera. *J. Lee*¹, *D. Kim*², *S. Baek*¹ and *B. Kwon*¹ *1. Hanyang University, Ansan, South Korea; 2. Korea Electronics Technology Institute, Gwang-ju, South Korea*

11:00

EB-06. 3-D Finite Element Analysis of Magnetic Forces Exerted on Stator End-windings of an Induction Motor. *R. Lin*¹ and *A. Arkkio*¹ *1. Helsinki University of Technology, Espoo, Finland*

11:15

EB-07. Magnetoelastic Characteristics of the Multilayered Magnetostrictive Thin Film with Polyimide Substrate for Micro Actuator. *H. Lee*¹ and *C. Cho*¹ *1. Mechanical Engineering, Inha University, Incheon, South Korea*

11:30

EB-08. Analysis of the force produced by speed-induced eddy currents in an xy-actuator. *A.F. Flores Filho*¹, *N.F. Baggio Filho*¹ and *M.A. da Silveira*² *1. Post-graduate Programme in Electrical Engineering, Federal University of Rio Grande do Sul, Porto Alegre, RS, Brazil; 2. Post-graduate Programme in Engineering – Environment, Energy and Materials, Lutheran University of Brazil, Canoas, RS, Brazil*

11:45

EB-09. An Extension to Multiple Coupled Circuits Modeling of Induction Machines to Include Variable Degrees of Saturation Effects. *M. Ojaghi*¹ and *J. Faiz*¹ *1. Department of Electrical and Computer Engineering, University of Tehran, Tehran, Iran*

12:00

EB-10. Switched Reluctance Motor with External Rotor for Fan in Air-condition. *H. Chen*¹ *1. College of Information and Electrical Engineering, China University of Mining & Technology, Xuzhou, Jiangsu, China*

12:15

EB-11. End turn leakage reactance of concentrated modular winding stators. *T. Cox*^{1,2}, *J. Eastham*¹ and *J. Proverbs*² *1. The University of Bath, Bath, United Kingdom; 2. Force Engineering, Shepshed, United Kingdom*

WEDNESDAY
MORNING
9:30

ROMA

Session EC MAGNETIC NANOSTRUCTURES I

Olav Hellwig, Chair

9:30

EC-01. X-ray and valence band photoemission microscopy of ultra-thin magnetic cobalt films on ruthenium. *A. Mascaraque*¹, *L. Perez*¹, *L. Aballe*², *T. Onur Mentes*², *J.F. Marco*³, *F. El Gabaly*^{4,5}, *C. Klein*⁵, *A.K. Schmid*⁵, *K.F. McCarty*⁶, *A. Locatelli*² and *J. de la Figuera*^{3,4} *1. Dpto. de Fisica de Materiales, Universidad Complutense de Madrid, Madrid, Madrid, Spain; 2. Elettra - Sincrotrone Trieste, Trieste, Italy; 3. Instituto de Quimica-Fisica Rocasolano, CSIC, Madrid, Madrid, Spain; 4. Centro de Microanalisis de Materiales, Universidad Autonoma de Madrid, Madrid, Madrid, Spain; 5. Berkeley National Laboratory, Berkeley, CA; 6. Livermore National Laboratories, Livermore, CA*

9:45

EC-02. Magnetostatic interactions in an artificial two-phase magnet. *S. Sievers*¹, *S. Schnittger*², *K. Braun*¹, *U. Siegner*¹ and *C. Jooss*² *1. Physikalisch-Technische Bundesanstalt, Braunschweig, Germany; 2. Institut für Materialphysik, Universität Göttingen, Göttingen, Germany*

10:00

EC-03. 360° domain wall generation in the soft layer of magnetic tunnel junctions. *F. Montaigne*¹, M. Hehn¹, D. Lacour¹, J. Briones¹, R. Belkhou^{2,3}, S. El Moussaoui^{2,3}, F. Maccherozzi^{2,3} and N. Rougemaille⁴. *1. Laboratoire de Physique des Matériaux, Nancy-University, CNRS, Vandoeuvre lès Nancy, France; 2. Synchrotron SOLEIL, Gif-sur-Yvette, France; 3. Synchrotron ELETTRA, Basovizza, Italy; 4. Institut Néel, CNRS & Université Joseph Fourier, Grenoble, France*

10:15

EC-04. Magnetic reversal in patterned nanostructures with circular exchange-bias. *M. Tanase*¹, A.K. Petford-Long¹, O.G. Heinonen², K.S. Buchanan³, J. Sort⁴ and J. Nogues⁴. *1. Materials Science Division, Argonne National Laboratory, Lemont, IL; 2. Seagate Technology, Bloomington, MN; 3. Center for Nanoscale Materials, Argonne National Laboratory, Lemont, IL; 4. Universitat Autònoma de Barcelona, Bellaterra, Spain*

10:30

EC-05. Static and dynamic properties of exchange bias modulated thin films. *C. Hamann*¹, J. McCord¹, R. Kaltoven², I. Mönch², R. Schäfer¹ and L. Schultz¹. *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany; 2. Institute for Integrative Nanosciences, IFW Dresden, Dresden, Germany*

10:45

EC-06. Dynamic splitting of azimuthal spin wave modes in circular magnetic dot in vortex ground state. *K.Y. Guslienko*¹, A.N. Slavin², V. Tyberkevych² and S.K. Kim¹. *1. Research Center for Spin Dynamics and Spin-Wave Devices and Nanospintronics Laboratory, Seoul National University, Seoul, South Korea; 2. Department of Physics, Oakland University, Rochester, MI*

11:00

EC-07. Enhancement of superconductive vortex pinning through formation of magnetic vortices. *A. Hoffmann*^{1,2}, L. Fumagalli³, N. Jahedi³, J.C. Sautner³, J.E. Pearson¹, G. Mihajlović¹ and V. Metlushko³. *1. Materials Science Division, Argonne National Laboratory, Argonne, IL; 2. Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL; 3. Electrical and Computer Engineering, University of Illinois at Chicago, Chicago, IL*

11:15

EC-08. Beams of spin waves guided by permalloy micro-stripes. *V.E. Demidov*¹, S.O. Demokritov¹, K. Rott², P. Krzysteczko² and G. Reiss². *1. Institute for Applied Physics, University of Muenster, Muenster, Germany; 2. Department of Physics, Bielefeld University, Bielefeld, Germany*

11:30

EC-09. Direct magnetic patterning on paramagnetic FeAl sheets by ion irradiation through poly(methyl methacrylate) and porous alumina shadow masks. *E. Menéndez*¹, J. Sort², E. Jiménez³, J. Camarero³, O. Liedke⁴, J. Fassbender⁴, D. Baró¹, S. Suriñach¹, S. Deevi⁵, K. Rao⁶, A. Weber⁷, L. Heyderman⁷, J. Sommerlatte⁸, K. Nielsch⁸ and J. Nogues⁹. *1. Departament de Física, Universitat Autònoma de Barcelona, 08193 Bellaterra, Barcelona, Spain; 2. ICREA and Departament de Física, Universitat Autònoma de Barcelona, 08193 Bellaterra, Spain; 3. Surface Science Lab (LASUAM, Lab. de Física de Superfícies), Dpto. Física de la Materia Condensada, Universidad Autónoma de Madrid, 28049 Madrid, Barcelona, Spain; 4. Institute of Ion Beam Physics and Materials Research, Forschungszentrum Dresden, 01314 Rossendorf, Germany; 5. Research Center, Chrysalis Technologies Incorporated, 23234 Richmond, WA; 6. Department of Materials Science and Engineering, Royal Institute of Technology, 10044 Stockholm, Sweden; 7. Paul Scherrer Institut, 5232 Villigen, Switzerland; 8. Max Planck Institute of Microstructure Physics, 06120 Halle, Germany; 9. ICREA and Institut Català de Nanotecnologia, Campus UAB, 08193 Bellaterra, Spain*

11:45

EC-10. Transverse magnetization in Nickel nanowire arrays patterned from Cu/Ni/Cu epitaxial films. *M. Ciria*¹, J.L. Diez-Ferrer², J.I. Arnaudas^{2,1}, B.G. Ng³, F.J. Castaño³, R.C. O'Handley³, E.S. Friend³ and C.A. Ross³. *1. ICMA, CSIC-Universidad de Zaragoza, Zaragoza, Spain; 2. Instituto de Nanociencia de Aragón, Universidad de Zaragoza, Zaragoza, Spain; 3. Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA*

12:00

EC-11. Magnetostatic dipolar domain wall pinning in chains of Permalloy triangular rings micromagnets. *P. Vávassori*^{1,2}, D. Bisero², V. Bonanni², A. Busato², M. Grimsditch³, K. Lebecki⁴, V. Metlushko⁵ and B. Ilic⁶. *1. CIC nanoGUNE, San Sebastian, Spain; 2. CNISM, CNR-INFM S3, and Dipartimento di Fisica, Università di Ferrara, Ferrara, Italy; 3. Materials Science Division, Argonne National Laboratory, Argonne, IL; 4. Institute of Physics, Polish Academy of Sciences, Warsaw, Poland; 5. Department of Electrical and Computer Engineering, University of Illinois at Chicago, Chicago, IL; 6. Cornell Nanofabrication Facility, Cornell University, Ithaca, NY*

12:15

EC-12. Partial frequency band gap in 1D magnonic crystals. *M. Kostylev*¹, G. Gubbiotti², P. Schrader¹, G. Carlotti², A.O. Adeyeye³, S. Goolaup³, N. Singh³ and R.L. Stamps¹. *1. School of Physics, University of Western Australia, Crawley, WA, Australia; 2. CNISM, Dipartimento di Fisica, Università di Perugia, Perugia, Italy; 3. Department of Electrical and Computer Engineering, National University of Singapore, Singapore, Singapore*

WEDNESDAY
MORNING
9:30

PARIS

11:00

Session ED
PERPENDICULAR MEDIA

S. Piramanayagam, Chair

9:30

ED-01. Head-to-SUL spacing reduction with a magnetic seed and the effect on perpendicular recording characteristics. *G. Choe*¹, *M. Minardi*¹, *K. Zhang*¹ and *M. Mirzamaani*¹. *Hitachi GST, 5600 Cottle Road, San Jose, CA*

9:45

ED-02. Reduction of transition layer thickness showing incoherent switching behavior in single CoCrPt-SiO₂ perpendicular media. *H. Jung*¹, *M. Kuo*¹, *S. Malhotra*¹ and *G. Bertero*¹. *Western Digital Media Inc., San Jose, CA*

10:00

ED-03. Compositional structure and magnetic properties of CoCrPt-SiO_x Perpendicular Recording Medium. *M. Futamoto*¹, *T. Handa*¹ and *Y. Takahashi*². *1. Faculty of Science and Engineering, Chuo University, Tokyo, Japan; 2. Central Research Laboratory, Hitachi, Ltd., Tokyo, Japan*

10:15

ED-04. Exactly Lattice Matched Novel Under Layers (LML) in Perpendicular Media. *A. Ajan*¹, *T. Sugimoto*¹ and *T. Uzumaki*¹. *1. Magnetic Media Laboratory, Fujitsu Laboratories Ltd., 10-1 Morinosato-Wakamiya, Atsugi, Japan*

10:30

ED-05. Magnetic and Recording Characteristics of CoCrPt-Oxide Media with a Mixture of SiO₂ and TiO₂. *I. Tamai*¹, *R. Araki*¹ and *K. Tanahashi*¹. *1. Central Research Laboratory, Hitachi, Ltd., Odawara-shi, Kanagawa-ken, Japan*

10:45

ED-06. Investigation of high and low Mobility sputter conditions to enhance decoupling in oxide composite media. *H. Lee*¹, *S. Kong*², *H. Lee*², *H. Oh*², *V.W. Guo*¹, *J. Zhu*¹ and *D.E. Laughlin*¹. *1. Electrical and Computer Engineering, Carnegie Mellon University, Pittsburgh, PA; 2. Samsung Advanced Institute of Technology, Yongin-Si, Gyeonggi-Do, South Korea*

ED-07. High-Resolution TEM Analysis Of Perpendicular CoCrPt-SiO₂ Media. *R. Araki*¹, *Y. Takahashi*¹, *I. Takekuma*² and *S. Narishige*². *1. Central Research Laboratory, Hitachi Ltd., 1-280 Higashi-koigakubo Kokubunji-shi, Tokyo, Japan; 2. Central Research Laboratory, Hitachi Ltd., 2880 Kozu, Odawara, Kanagawa, Japan*

11:15

ED-08. Epitaxially grown FCC/BCC/HCP multi-underlayers for high performance perpendicular recording media. *G. Choe*¹, *X. Xu*¹, *K. Tang*¹ and *X. Bian*¹. *Hitachi GST, San Jose, CA*

11:30

ED-09. A General Method to Fabricate Exchange Coupled Composite Media with Graded Structure for Energy Assisted Magnetic Recording. *H. Zhao*¹, *H. Wang*¹ and *J. Wang*¹. *ECE, University of Minnesota, Minneapolis, MN*

11:45

ED-10. Tuning pinning-site size of percolated perpendicular media (PPM) fabricated on pre-patterned substrates. *M. Rahman*¹, *C. Lai*¹ and *D. Suess*². *1. Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan; 2. Solid state physics, Vienna University of Technology, Vienna, Austria*

12:00

ED-11. Effect of carbon cosputtering in the growth of ultra-thin FePt particulate films on oxidized Si substrates. *P. Alagarsamy*¹, *S. Tomoko*², *T. Yukiko*¹ and *K. Hono*^{1,2}. *1. Magnetic Materials Center, National Institute for Materials Science, Tsukuba, Ibaraki, Japan; 2. Graduate School of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan*

12:15

ED-12. Effect of carbon mixing on the perpendicular anisotropy of FePt thin film. *S. Lee*¹, *M. Kim*¹ and *J. Park*¹. *1. Materials Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, South Korea*

WEDNESDAY
MORNING
9:30

LONDRES

11:00

Session EE
MAGNETIC NANOPARTICLES I

Gangping Ju, Chair

9:30

EE-01. Radio-frequency transverse susceptibility studies of effective magnetic anisotropy in nanoparticle assemblies. *H. Srikanth¹, P. Poddar^{2,1}, M. Morales¹ and N. Frey¹ 1. Department of Physics, University of South Florida, Tampa, FL; 2. National Chemical Laboratory, Pune, India*

9:45

EE-02. Magnetic properties characterization of single IBICVD fabricated magnetic particles. *T. Suzuki¹, Y. Pogoryelov¹ and A. Htoo¹ 1. Information Storage Materials Laboratory, Toyota Technological Institute, Nagoya, Aichi, Japan*

10:00

EE-03. Ground states in ferromagnetic nanotubes. *P. Landeros¹, O. Suarez¹, A. Cuchillo¹ and P. Vargas¹ 1. Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Valparaíso, Chile*

10:15

EE-04. A study of the magnetic behavior of Ni/Cu multilayer nanowire arrays, using FORC diagrams. *F. Beron¹, L. Carignan¹, D. Menard¹ and A. Yelon¹ 1. Génie physique, École Polytechnique de Montréal, Montréal, QC, Canada*

10:30

EE-05. Magnetic properties of metal/silicon nanocomposites tailored by specific metal precipitation. *P. Granitzer¹, K. Rumpf¹ and H. Krenn¹ 1. Institute of Physics, Karl Franzens University Graz, Graz, Austria*

10:45

EE-06. Polymer nanocomposites with embedded Cobalt nanoparticles. *S.N. Kale¹, S.H. Hatamie¹ and S.D. Kulkarni² 1. Department of Electronics-Science, Fergusson College, Pune, Maharashtra, India; 2. Centre for Materials Characterization, National Chemical Laboratory, Pune, Maharashtra, India*

EE-07. Temperature Dependence of Magnetic Correlations within a Magnetite Nanoparticle Assembly. *K. Krycka¹, C. Hogg², Y. Ijiri³, R. Booth², J. Borchers¹, W. Chen¹, M. Laver¹, T. Gentile¹, B. Maranville¹, B. Breslauer³ and S. Majetich² 1. NIST Center for Neutron Research, Gaithersburg, MD; 2. Carnegie Mellon University, Pittsburgh, PA; 3. Oberlin College, Oberlin, OH*

11:15

EE-08. First-order Magnetic Phase Transition in Manganese Phosphide Nanorods. *R. Booth¹ and S. Majetich¹ 1. Physics Department, Carnegie Mellon University, Pittsburgh, PA*

11:30

EE-09. Self-assembly Nanoscale Triangular Shaped Fe₆₄Ni₃₆ Dot Arrays. *D. Niu¹, X. Zou², J. Wu² and Y. Xu¹ 1. Spintronics and Nanodevice Laboratory, Department of Electronics, The University of York, York, United Kingdom; 2. Department of Physics, University of York, York, United Kingdom*

11:45

EE-10. Monodisperse doped iron core-shell nanoclusters: synthesis, transport and magnetic properties. *Y. Qiang¹, A. Sharma¹ and D. Meyer¹ 1. Physics, University of Idaho, Moscow, ID*

12:00

EE-11. Porous Silicon/Metal Hybrid System with Ferro and Paramagnetic Behaviour. *K. Rumpf¹, P. Granitzer¹ and H. Krenn¹ 1. Institute of Physics, Karl Franzens University Graz, Graz, Austria*

12:15

EE-12. Electrical Resistance and Magnetoresistance of Glass Ceramics Containing Magnetite Nanoparticles. *P. Allia¹, F. Celegato², M. Coisson², P. Tiberto², F. Vinai² and O. Bretcanu³ 1. Politecnico di Torino, Torino, Italy; 2. INRIM, Torino, Italy; 3. Imperial College, London, United Kingdom*

WEDNESDAY
MORNING
9:30

BERLIN

Session EF
RECORDING PHYSICS, MODELS AND THEORY - I
Masukazu Igarashi, Chair

9:30

EF-01. Switching field distribution reduction and effective write gradient enhancement in domain wall assisted media. *A.Y. Dobin¹ 1. Seagate Technology LLC, Fremont, CA*

9:45

EF-02. A Simple Model for Optimal Read Width due to Finite Write Width and Off-track Interference. *Z. Jin¹ and H.N. Bertram^{1,2} 1. Hitachi GST, San Jose, CA; 2. CMRR, UCSD, La Jolla, CA*

10:00

EF-03. Micromagnetic Study of Short and Long Yoke PMR Head Trailing Shield. *A.F Torabi¹, D. Bai², T. Pan², S. Li², S. Song², L. Zhong², L. Wang², K. Stoev² and S. Mao² 1. Western Digital Corporation, San Jose, CA; 2. Western Digital Corporation, Fremont, CA*

10:15

EF-04. Reduction in Switching Field for a Granular Perpendicular Medium Using Microwave Assisted Magnetic Recording. *S. Batra¹ and W. Scholz¹ 1. Seagate technology, Pittsburgh, PA*

10:30

EF-05. A Trailing Shield Perpendicular Writer Design with Tapered Write Gap for High Density Recording. *L. Guan¹, J. Smyth¹, M. Dovek¹, S. Chan² and T. Shimizu² 1. Headway Technologies, Milpitas, CA; 2. SAE Magnetics (H.K.) Ltd, Hong Kong, China*

10:45

EF-06. Time-dependent fields and anisotropy dominated magnetic media. *K. Rivkin¹, N. Tabat¹ and S. Foss-Schroeder¹ 1. Seagate Technology, Edina, MN*

11:00

EF-07. Effect Of Interlayer on Read Write Process in Perpendicular Recording. *K. Gao¹, V. Sapozhnikov¹, A. Zheng² and O. Heinonen¹ 1. Seagate Technology, Bloomington, MN; 2. Seagate Technology, Fremont, CA*

11:15

EF-08. Infulence of negative field on media noise in combination of capped medium and shielded pole head. *T. Ichihara¹, H. Kashiwase¹, H. Nakagawa¹, H. Nemoto¹ and M. Mochizuki² 1. Central Research Laboratory, Hitachi Ltd., Odawara, Kanagawa, Japan; 2. Hitachi Grobal Storage Technologies, Fujisawa, Kanagawa, Japan*

11:30

EF-09. Investigation on magnetic fields from field genarating layer in MAMR. *K. Yoshida¹, E. Uda¹, N. Udagawa¹ and Y. Kana² 1. Information and Communications Engineering, Kogakuin University, Tokyo, Japan; 2. Niigata Institute of Technology, Kashiwazaki, Niigata, Japan*

11:45

EF-10. Effect of media reversal mode on head footprint. *B.F Valcu¹, B. Allimi², A. Dobin¹, R. Lynch¹ and R. Brockie¹ 1. Seagate Technology, Fremont, CA; 2. Department of Materials Science and Engineering, University of Connecticut, Storrs, CT*

12:00

EF-11. Magnetic recording readback responses in three-dimensions for multi-layered recording media configurations. (Invited) *R. Wood¹ and D.T. Wilton² 1. HDD AdTech, Hitachi GST, San Jose, CA; 2. School of Mathematics and Statistics, University of Plymouth, Plymouth, United Kingdom*

WEDNESDAY
MORNING
9:30

AMSTERDAM

Session EG SOFT MAGNETIC MATERIALS AND APPLICATIONS II

Francis Johnson, Chair
Jorge Guerra, Chair

9:30

EG-01. Direct observation of magnetocaloric effect with pulsed-field magnet. *T.T. Nguyen¹, E. Brück¹, C. D. T¹, O. Tegus², J. Klaasse¹ and J. Buschow¹ 1. Faculty of Science, Universiteit van Amsterdam, Van der Waals-Zeeman Institute for Experimental Physics, Amsterdam, Netherlands; 2. Inner Mongolia Normal University, Key Laboratory for Physics and Chemistry of Functional Materials, Hohhot, China*

9:45

EG-02. The dc & ac properties of soft magnetic materials for the operational conditions found in novel electrical devices. *H.V. Patel¹, M.J. Hall¹, O. Thomas¹ and S.C. Harmon¹ 1. Industry & Innovation Division, National Physical Laboratory, Hampton Road, Teddington, Middlesex, TW11 0LW, United Kingdom*

10:00

EG-03. Eddy current effects and pinning effects in Fe and Ni single crystals with low defect densities. *S. Takahashi¹ and S. Kobayashi¹ 1. Faculty of Engineering, Iwate University, Morioka, Japan*

10:15

EG-04. Experimental Prediction of Iron Losses in Electromagnetic Devices. *G. Almandoz¹, E. Ritchie², J. Poza¹ and A. Gonzalez³* *1. University of Mondragon. Faculty of Engineering, Arrasate, Spain; 2. Aalborg University. Institute of Energy Technology, Aalborg, Denmark; 3. ORONA Elevator Innovation Center, Hernani, Spain*

10:30

EG-05. Miniature iron-gallium actuator with displacement magnifying mechanism. *M. Ghodsi¹, T. Ueno¹, C. Sze Keat², T. Yano² and T. Higuchi¹* *1. Precision Eng. Department, The University of Tokyo, Tokyo, Japan; 2. Mechano Transformer Corporation, Kawasaki, Japan*

10:45

EG-06. Application of magnetoelastic sensors for monitoring of the combustion process in diesel engines for locomotives. *A. Bienkowski¹, R. Szweczyk^{1,2} and J. Salach¹* *1. Institute of Metrology and Measuring Systems, Warsaw University of Technology, Warsaw, Poland; 2. Industrial Research Institute for Automation and Measurements PIAP, Warsaw, Poland*

11:00

EG-07. Longitudinal and transverse magnetoimpedance in FeNi/Cu/FeNi multilayers with longitudinal and transverse anisotropy. *D. de Cos¹, J.M. Barandiaran¹, A. Garcia-Arribas¹, V.O. Vas'kovskiy² and G.V. Kurlyandskaya^{1,2}* *1. Electricity and Electronics, Basque Country University UPV-EHU, Leioa, Bizkaia, Spain; 2. Physics of Magnetic Phenomenon, Ural State University named under A.M.Gorky, Ekaterinburg, Russian Federation*

11:15

EG-08. Magnetorheological characteristics of carbonyl iron embedded suspension polymerized poly(methyl methacrylate) microbead. *J. You¹, B. Park¹ and H. Choi¹* *1. Department of Polymer Science and Engineering, Inha University, Incheon, South Korea*

11:30

EG-09. Effect of Slit Patterning Perpendicular to Magnetic Easy Axis In Thin Film Inductors. *T. Masai^{1,2} and Y. Kitamoto²* *1. TDK, Minami-alps city, Yamanashi pref., Japan; 2. Innovative and Engineerd Materials, Tokyo Institute of Technolgy, 4259 Nagatsuta, Midori-ku, Yokohama, Japan*

11:45

EG-10. Miniaturization of antenna using Y-type hexagonal ferrite. *K. Kawano¹ and Y. Okamoto¹* *1. Product Development HQ, TAIYO YUDEN CO.,LTD., Takasaki-shi, Japan*

12:00

EG-11. Development of Axial Flux Permanent Syncrnous Motor by using High-Density Magnetic Composites. *H. Nakai¹, T. Arakawa¹, K. Hiramoto¹, S. Tajima¹ and Y. Inaguma²* *1. Toyota Central R&D labs., INC., Aichi, Japan; 2. Daido Institute of Technology, Nagoya, Japan*

12:15

EG-12. Validation of Voltage and Current Waveforms of Nonlinear Inductors Computed with a Novel Finite Element Methodology. *R. Salas¹ and J. Pleite¹* *1. Tecnologia Electronica, Universidad Carlos III de Madrid, Leganés, Spain*

WEDNESDAY
MORNING
9:30

CARACAS

Session EH
MAGNETO-DIELECTRIC MATERIALS
J. Mira, Chair

9:30

EH-01. Spin control by doping non-magnetic ions in magnetic ordering type of multiferroic materials. *K. Choi¹, S. Kim¹, B. Lee² and C. Kim¹* *1. Physics, Kookmin Univ., Seoul, South Korea; 2. Hankuk University of Foreign Studies, Yongin, South Korea*

9:45

EH-02. Dielectric and magnetic properties of low-temperature sintered Ni_{0.24}Cu_{0.21}Zn_{0.55}Fe_{1.96}O₄+xPb_{0.95}Sr_{0.05}(Zr_{0.52}Ti_{0.48})O₃ composites. *L. Jia¹, H. Zhang¹, S. Bao¹ and Z. Zhong¹* *1. university of electronic science and technology of China, chengdu, Sichuan, China*

10:00

EH-03. Processing related magneto-dielectric properties of Ni-Zn-Co ferrite ceramics. *L. Kong¹, Z. Li¹ and G. Lin¹* *1. Temasek Laboratories, National University of Singapore, Singapore, Singapore*

10:15

EH-04. Dielectric properties of the charge-ordered oxyborate Fe₂OBO₃ *M. Sanchez-Andujar², J. Mira¹, B. Rivas-Murias², S. Yanez-Vilar², N. Biskup³, J. Rivas¹ and M. Senaris-Rodriguez²* *1. Fisica Aplicada, Universidade de Santiago de Compostela, Santiago de Compostela, Spain; 2. Quimica Fundamental, Universidade da Coruna, A Coruna, Spain; 3. ICMM, Consejo Superior de Investigaciones Científicas, Madrid, Spain*

10:30

EH-05. Magneto-electric Effects in Single Crystal Hexaferrite-Piezoelectric Bilayers. V. Mathe¹ and G. Srinivasan¹ *1. Physics, Oakland University, Rochester, MI*

10:45

EH-06. Anisotropic Susceptibility and Weak Magnetic Moment of YbMnO₃ Single Crystal. J. Fontcuberta¹, M. Gospodinov² and V. Skumryev³ *1. Institut de Ciència de Materials de Barcelona, CSIC, Campus UAB, 08193 Bellaterra, Spain; 2. Institute of Solid State Physics, Bulgarian Academy of Sciences, 1784 Sofia, Bulgaria; 3. Institut Català de Recerca i Estudis Avançats (ICREA), and Departament de Física, Universitat Autònoma de Barcelona, 08193 Bellaterra, Spain*

11:00

EH-07. Pressure effect on the magnetic ordering in BiMnO₃ C. Chou^{1,2}, C. Lin^{1,2}, S. Taran^{1,2}, C. Huang^{1,2}, J. Her^{1,2}, C. Sun^{1,2}, C. Chan^{1,2}, H. Sakurai³, E. Takayama-Muromachi³ and H. Yang^{1,2} *1. Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan; 2. Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, Taiwan; 3. National Institute for Materials Science, Tsukuba, Japan*

11:15

EH-08. Magnetic properties of Ga substituted NiCr_{1.9-x}Ga_xFe_{0.1}O₄ G. Ahn¹, S. Park¹, S. Park² and C. Kim² *1. HANARO Utilization Technology Development Center, Korea Atomic Energy Research Institute(KAERI), Daejeon, South Korea; 2. Dept. of Physics, Kookmin University, Seoul, South Korea*

11:30

EH-09. Synthesis and magneocaloric effect of functional perovskites by sol-gel reaction. K. Jeongju¹, A. Yangkyu¹ and C. Eun Jung² *1. Chemistry, Konyang University, Nonsan, Chungnam, South Korea; 2. Ophthalmic Optic, Konyang University, Nonsan, Chungnam, South Korea*

11:45

EH-10. Ferrimagnetic Ba_{0.5}Sr_{1.5}Zn₂Fe₁₂O₂₂ (Zn-Y) single crystal barium ferrites. J. Jalli^{1,2}, Y. Hong^{1,2}, S. Gee^{1,3}, J. Lee^{1,2}, S. Bae^{1,2}, G.S. Abo^{1,2}, A. Lyle^{1,2}, H. Han^{1,2}, J. Kim⁴, H. Lee⁴ and S. Lee⁴ *1. Electrical and Computer Engineering, University of Alabama, Tuscaloosa, AL; 2. MINT Center, University of Alabama, Tuscaloosa, AL; 3. Seagate Technology, Bloomington, MN; 4. Pohang Superconductivity Center, Pohang University of Science and Technology, Pohang, South Korea*

12:00

EH-11. Increment of saturation magnetization and reduction of electric coercive field in multiferroic Bi ferrite films by adding cobalt. H. Naganuma¹, J. Miura¹ and S. Okamura¹ *1. Department of Applied Physics, Tokyo University of Science, Tokyo, Japan*

12:15

EH-12. Influence of oxygen and nitrogen on magnetic properties of soft magnetic CoFeZr nanoparticles embedded in alumina dielectric matrix. A. Fedotov¹, J. Fedotova¹, Y. Kalinin², A. Sitnikov², V. Fedotova³ and Y. Ilyashuk¹ *1. Belarusian State University, Minsk, Belarus; 2. Voronezh State Technical University, Voronezh, Russian Federation; 3. Joint Institute of Solids and Semiconductors Physiscs, Minsk, Belarus*

WEDNESDAY
MORNING
9:00

POLIVALENTE

Session EL
PERMANENT MAGNET MACHINES III
(POSTER SESSION)
Jiabin Wang, Chair

EL-01. Determining parameters of a line-start interior permanent magnet synchronous motor model by the differential evolution. T. Mar ĉi ĉ¹, G. Stumberger^{2,1}, B. Stumberger^{2,1}, M. Hadziselimovi ĉ^{2,1} and P. Vrti ĉ¹ *1. TECES, Research and Development Centre for Electrical Machines, Maribor, Slovenia; 2. University of Maribor, Faculty of Electrical Engineering and Computer Science, Maribor, Slovenia*

EL-02. Design and performance measurement of high speed permanent magnet synchronous motor with full-ring magnet for axial-flow turbo fan. S. Jang¹, J. Park¹, K. Ko¹ and J. Hwang² *1. Electrical Engineering, Chungnam National University, Daejeon, South Korea; 2. MAGPLUS, Daejeon, South Korea*

EL-03. Finite element analysis of stator winding faults in permanent magnet brushless AC motors. J.A. Farooq¹, T. Raminosoa¹, A. Djerdir¹ and A. Miraoui¹ *1. Electrical Engineering and Control Systems, University of Technology Belfort Montbeliard, Belfort, France*

EL-04. Analysis method for considering the effect of magnetic cross saturation of IPMSM. Y. Kim¹, I. Jung¹, J. Hur¹ and J. Hong² *1. KETI, Bucheon, South Korea; 2. Hanyang University, Seoul, South Korea*

EL-05. Design and finite-element analysis of interior permanent magnet synchronous motor with flux barriers. B. Stumberger¹, G. Stumberger¹, M. Hadziselimovic¹, T. Marcic², P. Virtic², V. Gorican¹ and M. Trlep¹ *1. University of Maribor, Faculty of EE&CS, Maribor, Slovenia; 2. TECES, Development centre for Electrical Machines, Maribor, Slovenia*

EL-06. Performance of IPMSM for Electro-Hydraulic Power Steering with Electric Driven Pump Unit. Y. Kim¹, S. Rhyu¹, J. Hur¹ and J. Hong² *1. KETI, Bucheon, South Korea; 2. Hanyang University, Seoul, South Korea*

EL-07. Influence of driving methods on dynamic torque characteristic of high-speed permanent magnet synchronous motor with hall sensor. S. Jang¹, U. Lee¹, D. You¹, J. Park¹ and T. Sung². *1. Chungnam National University, Daejeon, South Korea; 2. Korea Electric Power Research Institute, Daejeon, South Korea*

EL-08. Thrust Ripple Minimization of Permanent Magnet Linear Synchronous Motor by the Notch and the Auxiliary-teeth. D. Lee¹, K. Jang¹ and G. Kim¹. *1. Electrical Engineering, Changwon National University, Changwon, Gyeongsangnam-do, South Korea*

EL-09. A Study on the Vibration Characteristic According to PM Arrangement in PMLSM. D. Lee¹, S. Lee¹, K. Jang¹ and G. Kim¹. *1. Electrical Engineering, Changwon National University, Changwon, Gyeongsangnam-do, South Korea*

EL-10. Flux Barrier Design to Improve Torque Characteristics of Double-layer Interior Permanent Magnet Synchronous Motor. S. Kim¹, J. Jung¹, J. Hong¹ and S. Lee². *1. Department of Mechanical Engineering, Hanyang University, Seoul, South Korea; 2. Research Center, Korea Institute of Industrial Technology, Gwangju, South Korea*

EL-11. Study on High Efficiency Performance in Interior Permanent Magnet Synchronous Motor with Double-layer PM Design. L. Fang¹, J. Jung¹, B. Lee¹ and J. Hong¹. *1. Department of Mechanical Engineering, Hanyang University, Seoul, South Korea*

EL-12. A new PMLSM having 9 pole 10 slot structure and its shape optimal design for detent force reduction. C. Koh¹, I. Hwang¹ and H. Yoon¹. *1. School of Electrical & Computer Engineering, Chungbuk National University, Cheongju, Chungbuk, South Korea*

**WEDNESDAY
MORNING
9:00**

POLIVALENTE

Session EM EXCHANGE BIAS II (POSTER SESSION)

Jordi Sort, Chair

EM-01. The role of uncompensated spins in exchange biasing. (Invited) H.J. Hug^{1,2}, I. Schmid¹ and P. Kappenberger¹. *1. Nanoscale Materials Science, Empa, Duebendorf, Switzerland; 2. Institute of Physics, University of Basel, Basel, Switzerland*

EM-02. Measuring exchange anisotropy in Fe/MnPd using inductive magnetometry. K.J. Kennewell¹, X. Ji², J. Hu¹, K.M. Krishnan² and R.L. Stamps¹. *1. School of Physics, University of Western Australia, Crawley, WA, Australia; 2. Materials Science and Engineering, University of Washington, Seattle, WA*

EM-03. Dependence of the training effect on the antiferromagnet structure in the domain state model for exchange bias. A.G. Bitermas¹, U. Nowak¹ and R.W. Chantrell¹. *1. Department of Physics, University of York, York, United Kingdom*

EM-04. Temperature Dependence of IrMn Pinning: Single Crystal versus Polycrystalline Effects. P. Pong¹, C.L. Dennis¹ and W.F. Egelhoff¹. *1. Magnetic Materials Group, National Institute of Standards and Technology, Gaithersburg, MD*

EM-05. Exchange coupling between an amorphous ferromagnet and a crystalline antiferromagnet. M. Fecioru-Morariu¹, G. Güntherodt¹, M. Rühlig², A. Lamperti³ and B. Tanner³. *1. Physikalisches Institut (IIA), RWTH Aachen University, Aachen, Germany; 2. Corporate Technology, CT MM 1, Innovative Electronics, SIEMENS AG, Erlangen, Germany; 3. Department of Physics, Durham University, Durham, United Kingdom*

EM-06. Local exchange anisotropy of epitaxial and polycrystalline MnIr/CoFe bilayers. H. Kato², T. Kato¹, S. Tsunashima² and S. Iwata¹. *1. Department of Quantum Engineering, Nagoya University, Nagoya, Aichi, Japan; 2. Department of Electrical Engineering and Computer Science, Nagoya University, Nagoya, Aichi, Japan*

EM-07. The significant enhancement of the thermal stability in Co/Cu/Co/IrMn spin valve through insert 1nm FeMn layer. L. Wang¹, Q.Q. Qin¹, H.X. Wei¹ and X.F. Han¹. *1. Institute of Physics, Beijing, China*

EM-08. Exchange bias in Cu/Ni/FeMn trilayer with perpendicular magnetic anisotropy. L.T. Tu¹ and C. Kim¹. *1. Department of Materials Science and Engineering, Chungnam National University, Daejeon, South Korea*

EM-09. Parallel and perpendicular exchange biases in epitaxial FePt-FeMn multilayers with different crystalline orientations. N.N. Phuoc¹ and T. Suzuki¹. *1. Information Storage Materials Laboratory, Toyota Technological Institute, Nagoya, Aichi, Japan*

EM-10. Enhanced Exchange Anisotropy by ultra-thin Co₂Fe_{100-x} (x > 80) Layer Insertion at the Interface of L1₂-ordered Mn₃Ir/Co₆₅Fe₃₅ Bilayers. K. Komagaki¹, M. Tsunoda², K. Noma¹, H. Kanai¹, K. Kobayashi¹, Y. Uehara¹ and M. Takahashi². *1. Advanced Head Technology Department, Head Division, FUJITSU LIMITED, Nagano, Japan; 2. Department of Electronic Engineering, Tohoku University, Sendai, Japan*

EM-11. Lateral grain size effect on exchange bias in polycrystalline FeNi/FeMn bi-layer films. P. Sharma¹, T. Huang¹, A. Sun¹ and J. Hsu¹. *1. Physics, National Taiwan University, Taipei, Taiwan*

EM-12. The influence of different Mn-oxide structures on the exchange bias field in NiFe/Mn-oxide bilayers. J. Guo¹, T. Chen¹, Y. Chiu¹, H. Ouyang¹, K. Lin¹, E. Vass² and J. van Lierop³. *1. Department of Materials Engineering, National Chung Hsing University, Taichung, Taiwan; 2. Institut für Experimentalphysik, University of Innsbruck, Innsbruck, Austria; 3. Department of Physics and Astronomy, University of Manitoba, Winnipeg, MB, Canada*

EM-13. Effect of the ferromagnetic layer thickness on the blocking temperature in IrMn/CoFe exchange couples. G. Vallejo-Fernandez¹, L.E. Fernandez-Outon¹, B. Kaeswurm¹ and K. O'Grady¹. *1. Physics, The University of York, York, North Yorkshire, United Kingdom*

EM-14. Probing the influence of in-plane roughness on magneto-resistance in spin-valves using off-specular reflectivity techniques. J. Park¹, C. Furjanic¹, D. Draganova¹, C. Chen¹, S.M. Watson², J.A. Borchers², M. Carey³, P. Sparks¹ and J.C. Eckert¹. *1. Physics, Harvey Mudd College, Claremont, CA; 2. NIST Center for Neutron Research, Gaithersburg, MD; 3. Hitachi Global Storage Technologies, San Jose, CA*

WEDNESDAY
MORNING
9:00

POLIVALENTE

Session EN
SHIELDING, LEVITATION AND TRANSPORT
(POSTER SESSION)
Claudio Aroca, Chair

EN-01. Intuitive operation of magnetically driven fish-type microrobot using smart interface. T. Honda¹, K. Ono¹ and J. Yamasaki¹ *1. Department of Applied Science for Integrated System Engineering, Kyushu Institute of Technology, Kitakyushu, Fukuoka, Japan*

EN-02. Three-dimensional motion of a small object by using a new magnetic levitation system having four I-shaped electromagnets. T. Ohji¹, H. Hara¹, K. Amei¹ and M. Sakui¹ *1. University of Toyama, Toyama, Japan*

EN-03. A Novel Design of a Disk-Shaped Bearingless PM Motor for Artificial Hearts. J. Asama¹, Y. Kishi¹ and A. Chiba¹ *1. Electrical Engineering, Tokyo University of Science, Noda, Chiba, Japan*

EN-04. Effect of the active damper coils of the superconducting magnetically levitated bogie in case of acceleration. S. Ohashi¹ *1. Electrical and Electric Engineering, Kansai University, Osaka, Japan*

EN-05. Assessing the Maglev Force Capabilities of Two Passive Flat Guideway Topologies when using Electrodynamic Wheels. J. Bird^{1,2} *1. Advanced Technology Center, General Motors Corporation, Torrance, CA; 2. Electrical and Computer Engineering, University of Wisconsin-Madison, Madison, WI*

EN-06. Magnetic levitation with minimum power consumption using disturbance compensation. J. Ahn¹, S. Kim², J. Lee¹ and J. Choi³ *1. Electrical Engineering, Hanyang University, Seoul, South Korea; 2. Electrical Engineering, Yuhan College, Buchon, Gyeonggi, South Korea; 3. Industry Application Research Division, Korea Electrotechnology Research Institute, Changwon, Gyeongnam, South Korea*

EN-07. Design and Dynamic Analysis of Rectangular-Surface Electromagnets for Levitation Applications. S. Jang¹, J. Choi¹, J. Park¹, H. Sung² and S. Sung² *1. Chungnam National University, Dae-jeon, South Korea; 2. Korea Institute of Machinery&Materials, Daejeon, South Korea*

EN-08. Basic Characteristics of an Active Thrust Magnetic Bearing with a Cylindrical Rotor Core. K. Hijikata¹, S. Kobayashi¹, M. Takemoto¹, Y. Tanaka¹, A. Chiba² and T. Fukao¹ *1. Mechanical Systems Engineering, Musashi Institute of Technology, Setagaya-ku, Tokyo, Japan; 2. Electrical Engineering, Tokyo University of Science, Noda-shi, Chiba, Japan*

EN-09. Magnetically-Levitated Steel Plate Conveyance System Using Electromagnets and a Transverse-Flux Linear Induction Motor. J. Choi¹ and Y. Baek¹ *1. Mechanical Engineering, Yonsei University, Seoul, South Korea*

EN-10. Combination resonance of a rigid body levitated above a diamagnetic slab. T. Sugiura¹ and T. Hosono¹ *1. Mechanical Engineering, Keio University, Yokohama, Japan*

EN-11. Dynamic shielded room for biomagnetism. D. Costandache¹ and O. Baltag¹ *1. University of Medicine and Pharmacy "Gr.T.Popa", Iasi, Romania*

EN-12. Magnetic shielding design for magneto-electronic devices protection. W. Wang¹ and Z. Jiang¹ *1. Electrical Engineering, University of Wisconsin - Milwaukee, Milwaukee, WI*

EN-13. Measurement and calculation of shielding performance of reinforced concrete structures. M. Zhang¹, Z. Zhao¹ and X. Cui¹ *1. North China Electric Power University, Baoding, Hebei, China*

EN-14. Reduction of magnetic shaking flux leakage from loosely coupled cylindrical magnetic shield shells having active compensation. I. Sasada¹ and R. Takahashi¹ *1. Applied Science for Electronics and Materials, Kyushu University, Kasuga, Japan*

EN-15. Analysis of perforated magnetic shields. P. Sergeant¹, R. Sabariego², G. Crevecoeur¹, C. Geuzaine² and L. Dupre¹ *1. Department of Electrical Energy, Systems and Automation, Ghent university, Gent, Belgium; 2. Department of Electrical Engineering and Computer Science, University of Liege, Liege, Belgium*

EN-16. Optimal Design and Analysis of Faraday Shield Used in High Frequency Coaxial Transformer. X. Yang¹ and J. Lu² *1. Province-Ministry Joint Key Laboratory of Electromagnetic Field and Electrical Apparatus Reliability, Hebei University of Technology, Tianjin, China; 2. School of Eng., Griffith University, Brisbane, QLD, Australia*

EN-17. Electromagnetic wave absorption properties of double layers absorbers made of hollow glass microspheres electroless plated with FeCoNiB and NiCoZn ferrites. M. Han¹, F. Xiao¹ and Y. Ou¹ *1. State Key Laboratory of Electronic Thin Films and Integrated Devices, University of Electronic Science and Technology of China, Chengdu, Sichuan, China*

EN-18. Open-type Magnetic Shield Structure and its Performance. M. Fujikura¹, K. Segawa¹, K. Chikuma¹, K. Fujisaki¹, J. Mino², T. Morita², T. Saito³, H. Hirano³ and T. Shinnoh³ *1. Nippon Steel corporation, Chiba, Japan; 2. Nippon Steel Engineering Co., LTD., Tokyo, Japan; 3. Kajima Corporation, Tokyo, Japan*

EN-19. The Estimation on the shield capability of the Magnetic Shielding Room depending on the setting direction of GO based on the analysis with Homogenization Method for Thin Steel Plate. Y. Tomizawa¹, K. Fujisaki^{2,3}, M. Fujikura², J. Mino⁴, S. Tamaki⁵ and T. Morita⁶ *1. Industrial Plant Engineering, Taiheikogyo Co.,Ltd, Toukai, Japan; 2. Technical Development Bureau, Nippon Steel Corp., Futtsu, Japan; 3. Graduate School of Environmental Studies, Tohoku University, Sendai, Japan; 4. Building Construction & Steel Structures, Nippon Steel Engineering Co.,Ltd, Chiyoda, Japan; 5. Nagoya Works, Nippon Steel Corp., Toukai, Japan; 6. NS Construction, Chiyoda, Japan*

EN-20. Open-Type Magnetically Shielded Room Combined with Square Cylinders made of Magnetic and Conductive Materials for MRI. K. Yamazaki¹, S. Hirotsato¹, K. Kamata², K. Muramatsu³, K. Kobayashi⁴ and A. Haga⁵ *1. Takenaka Corp., Chiba, Japan; 2. Kagoshima National College of Technology, Kagoshima, Japan; 3. Saga University, Saga, Japan; 4. Iwate University, Iwate, Japan; 5. Tohoku-Gakuin University, Miyagi, Japan*

EN-21. Shield Duct to Prevent Magnetic Field Leakage through Openings in Double-layered Magnetically Shielded Rooms. *K. Yamazaki¹, Y. Hatsukade², S. Tanaka² and A. Haga³* *1. Takenaka Corp., Chiba, Japan; 2. Toyohashi University of Technology, Toyohashi, Japan; 3. Tohoku-Gakuin University, Miyagi, Japan*

EN-22. Features of a Wall with Open-type Magnetic Shield. *T. Saito¹* *1. Kajima Corporation, Tokyo, Japan*

EN-23. Analysis of the shielding effectiveness of rectangular enclosure of metal structures with apertures. *M. Zhang¹, Z. Zhao¹, C. Gao¹ and S. Wang²* *1. North China Electric Power University, Baoding, Hebei, China; 2. Northeast Electric Power Design Institute, Changchun, Jilin, China*

**WEDNESDAY
MORNING
9:00**

POLIVALENTE

**Session EO
MOLECULAR AND NOVEL MATERIALS-II
(POSTER SESSION)**

Clara Marquina, Chair

EO-01. Effect of La-substitution on magnetic and ferroelectric properties of $\text{Bi}_{(1-x)}\text{La}_x\text{Dy}_{0.3}\text{FeO}_3$ system. *P. Kovur¹, S.P. Duttgupta¹ and V.R. Palkar¹* *1. Electrical Engineering, Indian Institute of Technology Bombay, Mumbai, Maharashtra, India*

EO-02. Thermomagnetic characterization of the CeNi_xCr compound. *T. Tolinski¹, A. Kowalczyk¹, M. Reiffers², E. Gazo², M. Zapotokova² and G. Chelkowska³* *1. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland; 2. Institute of Experimental Physics, SAS, Kosice, Slovakia; 3. Institute of Physics, Silesian University, Katowice, Poland*

EO-03. Two dimensional ferromagnetic clusters in $\text{Ho}_{0.8}\text{La}_{0.2}\text{Mn}_2\text{O}_5$. *H. Chou¹, C. Yu¹, C. Wang², C. Wu² and W. Li²* *1. Physics, National Sun Yat-sen University, Kaohsiung, Taiwan; 2. Physics and Center for Neutron Beam Application, National Central University, Jhongli, Taiwan*

EO-04. The switching behavior of spin transition $[\text{Fe}(\text{PM-BiA})_2(\text{NSC})_2]$ compound derived from pressure pulse type experiments. *R. Tanasa¹, A. Stancu¹, J. Linares², E. Codjovi², F. Varret² and J. Letard³* *1. Department of Physics, "Alexandru Ioan Cuza" University, Iasi, Romania; 2. Groupe d'Etude de la Matière Condensée (GEMaC) CNRS-UMR 8635, Université de Versailles, Versailles, France; 3. Groupe des Sciences Moléculaires, Institut de Chimie de la Matière Condensée de Bordeaux, UPR No. 9048 CNRS-Université Bordeaux I, Pessac, France*

EO-05. Magnetic Properties of $\text{Zr}_9\text{Ni}_{11}$ Intermetallic Compound. *V. Provenzano¹, R.D. Shull¹, R.M. Waterstrat¹, L.H. Bennett^{1,2}, E. Della Torre^{1,2} and H. Seyoum³* *1. Magnetic Materials Group, NIST, Gaithersburg, MD; 2. Physics Department, George Washington University, Washington, DC; 3. Physics Department, University of the District of Columbia, Washington, DC*

EO-06. First-Order Reversal Curve Analysis of Spin-Transition Thermal Hysteresis Under Pressure in Terms of Physical-Parameter Distributions and Their Correlations. *A. Rotaru^{1,2}, J. Linares¹, E. Codjovi¹, F. Varret¹ and A. Stancu²* *1. Physique, GEMAC-Versailles University, Versailles, Yvelines, France; 2. Physique, Alexandru Ioan Cuza University, Iasi, Iasi, Romania*

EO-07. Thermodynamic and electronic properties of DyNi_4Si compound. *M. Falkowski¹, A. Kowalczyk¹, M. Reiffers², T. Tolinski¹, E. Gazo², M. Zapotokova² and G. Chelkowska³* *1. Institute of Molecular Physics, Polish Academy of Sciences, Smoluchowskiego 17, Poznan, Poland; 2. Institute of Experimental Physics, Slovak Academy of Sciences, Watsonova 47, Kosice, Slovakia; 3. Institute of Physics, Silesian University, Uniwersytecka 4, Katowice, Poland*

EO-08. Multiferroic, electronic and structural properties of $\text{Sr}_2\text{TiMnO}_6$ perovskite: experimental and ab-initio studies. *J.A. Rodriguez¹, D.A. Landinez-Tellez¹, C. Salazar-M¹, P. Pureur², F.E. Fajardo¹ and J. Roa-Rojas¹* *1. Dept. of Physics, Universidad Nacional de Colombia, Bogotá, D. C., Colombia; 2. Institute of Physics, Universidade Federal do Rio Grande do Sul, Proto Alegre RS, Brazil*

EO-09. Physical Properties in Powder, Bulk and Thin Films of $\text{La}_{2/3}\text{Ca}_{1/3}\text{Cr}_x\text{Mn}_{(1-x)}\text{O}_3$ with Low Doping. *D.L. Quintero¹ and D. Girata¹* *1. Physics Institute, Universidad de Antioquia, Medellin, Antioquia, Colombia*

EO-10. Magnetic relaxation behavior in $\text{Nd}_{0.5}\text{Sr}_{0.5}\text{MnO}_3$: observation of negative imaginary component of ac magnetic susceptibility. *A.N. Ulyanov¹, H.D. Quang², K.W. Lee³, S.C. Yu⁴, N.H. Sinh⁵, Y.M. Kang¹ and S.I. Yoo¹* *1. Department of Materials Science and Engineering, Seoul National University, Seoul 151-744, South Korea; 2. Solid State Physics Group, Department of Physics & Astronomy and SUPA Graduate School, University of Glasgow, G12 8QQ, United Kingdom; 3. Korea Research Institute of Standards and Science, Yusong, Taejeon 305-340, South Korea; 4. Department of Physics, Chungbuk National University, Cheongju 361-763, South Korea; 5. Cryogenics Laboratory, Department of Physics, College of Natural Science, Hanoi National University, 334 Nguyen Trai Road, Thanh Xuan, Hanoi, Viet Nam*

EO-11. Synthesis and characterization of multiferroic polycrystalline transition metal doped BiFeO_3 thin films. *P. Kharel¹, S. Talebi^{2,1}, C. Sudakar¹, M.B. Sahana¹, V.M. Naik², R. Naik¹ and G. Lawes¹* *1. Department of Physics and Astronomy, Wayne State University, Detroit, MI; 2. Department of Natural Sciences, University of Michigan-Dearborn, Dearborn, MI*

**WEDNESDAY
MORNING
9:00**

POLIVALENTE

**Session EP
MAGNETODYNAMICS AND MILLIMETRE WAVE DEVICES
(POSTER SESSION)**

Andrei Slavin, Chair

EP-01. Influence of current induced magnetic inhomogeneities on spin wave propagation. *T. Neumann¹, A.A. Serga¹, M.P. Kostylev² and B. Hillebrands¹* *1. Fachbereich Physik und Forschungsschwerpunkt MINAS, TU Kaiserslautern, Kaiserslautern, Germany; 2. School of Physics, University of Western Australia, Crawley, WA, Australia*

EP-02. A YIG/GGG/GaAs-Based Magnetically Tunable Wideband Microwave Band-Pass Filter Using Cascaded Band-Stop Filters*. G. Qiu¹, B.T. Wang² and C.S. Tsai^{1,3} *1. Dept of Electrical Engineering and Computer Science, and Institute of Surface and Interface Science, University of California, Irvine, CA; 2. Wang, NMR Inc., Livermore, CA; 3. Institute of Electrooptics Engineering, National Taiwan University, Taipei, Taiwan*

EP-03. Bistable control of ferromagnetic resonance frequencies in ferromagnetic trilayered dots. Y. Nozaki¹, K. Tateishi¹, S. Taharazako¹, S. Yoshimura¹ and K. Matsuyama¹ *1. Dept. of Electronics, Kyushu University, Fukuoka, Japan*

EP-04. An Electric Field Tunable Millimeter-Wave Ferrite-Piezoelectric Phase Shifter. A.S. Tatarenko¹ and G. Srinivasan¹ *1. Physics, Oakland University, Rochester, MI*

EP-05. Design of Scandium and Indium doped hexaferrite microstripline phase shifters for X-band applications. T. Sakai¹, C. Chinnasamy¹, V. Ilanchelilyan¹, S. Yoon¹, C. Vittoria¹ and V.G. Harris¹ *1. Electrical&Computer Engineering, Northeastern university, Boston, MA*

EP-06. Propagation characteristics of magnetostatic surface waves in a YIG-based one-dimensional magnonic crystal composed of rubber magnets. K. Togo¹, K. Hatafuku¹, M.E. Dokukin¹, J. Kim¹, K. Shin² and M. Inoue¹ *1. Toyohashi University of Technology, Toyohashi, Japan; 2. Kyungsung University, Pusan, South Korea*

EP-07. A magnetosensitive microwave absorption characterization of terbium. G. Alvarez¹, H. Montiel², R. Zamorano³ and R. Valenzuela¹ *1. Departamento de Materiales Metálicos y Cerámicos, Instituto de Investigaciones en Materiales de la Universidad Nacional Autónoma de México, Ciudad de México, México DF, Mexico; 2. Centro de Ciencias Aplicadas y Desarrollo Tecnológico de la Universidad Nacional Autónoma de México, Ciudad de México, México DF, Mexico; 3. Departamento de Ciencias de los Materiales, Instituto Politécnico Nacional, Ciudad de México, México DF, Mexico*

EP-08. Magnetic tuning of surface acoustic wave devices within high frequency range. C. Cavaco¹, L.A. Francis^{2,1}, L. Lagae¹ and G. Borghs¹ *1. IMEC, Leuven, Belgium; 2. Université catholique de Louvain, Louvain-la-Neuve, Belgium*

EP-09. Microwave Absorption Properties of The Hierarchically Branched Ni Nanowires Composites. L. Qiao¹, J. Wang¹, X. Han¹, B. Gao¹, F. Wen¹ and F. Li¹ *1. Lanzhou University, Institute of Applied Magnetism, Key Laboratory for Magnetism and Magnetic Materials of Ministry of Education, Lanzhou, Gansu, China*

EQ-02. Temperature dependent magneto-transport studies in ferromagnetic Ge_{1-x}Mn_xTe. C. Sim^{1,2}, W. Chen², S. Lim², J. Bi¹, K. Teo¹, T. Liew² and T. Chong² *1. Electrical & Computer Engineering, National University of Singapore, Singapore, Singapore; 2. Data Storage Institute, Singapore, Singapore*

EQ-03. Exponential decrease of neutral dangling bonds density in rare-earth doped amorphous Si films. W. Iwamoto¹, P.G. Pagliuso¹, C. Rettori¹ and A.R. Zanatta² *1. DEQ, IFGW - Unicamp, Campinas, São Paulo, Brazil; 2. Instituto de Física de São Carlos, USP, São Carlos, São Paulo, Brazil*

EQ-04. Study on absence of room-temperature ferromagnetism in the Mn-AlN films with various Mn concentrations. T. Sato¹, Y. Endo², Y. Kawamura¹, F. Kirino³, R. Nakatani¹ and M. Yamamoto¹ *1. Department of Materials Science and Engineering, Osaka University, Osaka, Japan; 2. Department of Electrical and Communication Engineering, Tohoku University, Sendai, Japan; 3. Conservation of Cultural Property, Tokyo National University of Fine Arts and Music, Tokyo, Japan*

EQ-05. Growth parameter dependence of structural characterization of diluted magnetic semiconductor (Ga,Cr)As. J. Lu¹, J. Bi¹, W. Wang¹, G. Gan¹, H. Meng¹, H. Zheng¹ and J. Zhao¹ *1. State Key Laboratory for Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, Beijing, China*

EQ-06. Coexistence of ferromagnetism and paramagnetism in highly dilute Ga_{1-x}Mn_xN. D. Sedmidubský¹, Z. Sofer¹, J. Hejtmánek², M. Maryško² and K. Jurek² *1. Institute of Chemical Technology, Prague, Czech Republic; 2. Institute of Physics ASCR, v.v.i., Prague, Czech Republic*

EQ-07. Effect of strain relaxation on the anisotropic magnetoresistance of GaMnAs microbars. E. De Ranieri¹, K. Olejník², K. Vyborný², A.C. Irvine¹, R.P. Campion³, B.L. Gallagher³, T. Jungwirth^{2,3}, H. Sirringhaus¹ and J. Wunderlich^{4,2} *1. Microelectronics Research Centre, University of Cambridge, Cambridge, United Kingdom; 2. Institute of Physics ASCR, Prague, Czech Republic; 3. School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom; 4. Hitachi Cambridge Laboratory, Cambridge, United Kingdom*

EQ-08. Preparation of (Ge_{1-y}Pb_y)_{1-x}Mn_xTe thin films and their magnetic properties. H. Asada¹, Y. Fukuma², D. Kitabori¹, A. Ohji¹, Y. Kamimoto¹ and T. Koyanagi¹ *1. Department of Materials Science and Engineering, Yamaguchi University, Ube, Japan; 2. Yamaguchi Prefectural Industrial Technology Institute, Ube, Japan*

EQ-09. Properties of ternary rare earth REXY compounds with 18 valence electrons. F. Casper¹ and C. Felser¹ *1. Institute for inorganic and analytical chemistry, Mainz, Germany*

EQ-10. Effect of local magnetic field on the transport properties of GaMnAs. J. Suh^{1,2}, J. Chang¹, E. Kim², M. Sapozhnikov³ and A. Fraerman³ *1. Center for Spintronics Research, KIST, Seoul, South Korea; 2. Quantum-Function Spinics Lab. and Department of Physics, Hanyang University, Seoul, South Korea; 3. Institute for Physics of Microstructures RAS, Nizhny Novgorod, Russian Federation*

WEDNESDAY
MORNING
9:00

POLIVALENTE

Session EQ MAGNETIC SEMICONDUCTORS-II (POSTER SESSION)

Benjamin Martinez, Chair

EQ-01. Magnetoresistance in Co/ZnO films. X. Li^{1,2}, Z. Quan², X. Xu² and H. Wu^{2,1} *1. College of Chemistry and Chemical Engineering, Taiyuan University of Technology, Taiyuan, Shanxi, China; 2. School of Chemistry and Materials Science, Shanxi Normal University, Linfen, Shanxi, China*

WEDNESDAY
MORNING
9:00

POLIVALENTE

Session ER
MAGNETIC SEMICONDUCTORS - III
(POSTER SESSION)
Alicia Andres, Chair

ER-01. Structural and magnetic properties of Co-doped ZnO thin films. *M. Fonin¹, G. Mayer¹, S. Voss¹, E. Goering², U. Rüdiger¹, R. Schneider³ and D. Gerthsen³* *1. Fachbereich Physik, Universität Konstanz, Konstanz, Germany; 2. Max Planck-Institut für Metallforschung, Stuttgart, Germany; 3. Laboratorium für Elektronenmikroskopie, Universität Karlsruhe, Karlsruhe, Germany*

ER-02. Ferromagnetism observed in transition metal doped high K oxides. *Q. Wen¹, H. Zhang¹, Y. Song¹, Q. Yang¹ and Y. Liu¹* *1. State Key Laboratory of Electronic Films and Integrated Devices,, University of Electronic Science and Technology of China, Chengdu, Sichuan, China*

ER-03. Evidence of oxygen vacancies enhancing the room temperature ferromagnetism in CeO₂ nanopowders. *M. Li¹, S. Ge¹, Y. Zuo¹, X. Zhou¹, L. Zhang¹ and S. Yan¹* *1. Lanzhou University, Lanzhou, China*

ER-04. Zeeman splitting induced positive magnetoresistance in Co-doped ZnO and Co-doped Cu₂O ferromagnetic nanoparticles. *Y. Tian^{1,2}, J. Antony¹, R. Souza¹, D. Meyer¹, A. Sharma¹ and Y. Qiang¹* *1. Department of Physics, University of Idaho, Moscow, ID; 2. School of Physics and Microelectronics, Shandong University, Jinan, Shandong, China*

ER-05. ZnO:Co films obtained by oxidation of ZnTe and Co diffusion. *I. Mínguez Bacho¹, O. de Melo^{2,3}, R. Sanz¹, A. Climent-Font^{3,4}, A. Jacas Rodriguez¹ and M. Hernández-Vélez^{1,3}* *1. ICMN-CSIC, Madrid, Spain; 2. Facultad de Física, Universidad de La Habana, La Habana, Cuba; 3. Departamento de Física Aplicada, Universidad Autónoma de Madrid, Madrid, Spain; 4. Centro de Micro-Análisis de Materiales, Universidad Autónoma de Madrid, Madrid, Spain*

ER-06. Magnetic properties of TiO₂/Co₃O₄ system. *A. Serrano¹, A. Quesada^{1,4}, I. Lorite², L. Pérez¹, J. Fernandez², J. Costa-Kramer³, M. Martín-González³, S. Steplecaru³, J. Llopis¹ and M. García¹* *1. Dpt Material Science, Universidad Complutense de Madrid, Madrid, Spain; 2. Dpt Electroceramics, Institute for Ceramic and glasses - CSIC, Madrid, Madrid, Spain; 3. Institute of Microelectronics, CSIC, Madrid, Madrid, Spain; 4. Institut for applied magnetism, Universidad Complutense de Madrid, Las Rozas, Madrid, Spain*

ER-07. EXPERIMENTAL EVIDENCE OF DOUBLE-EXCHANGE CONTRIBUTION TO FERROMAGNETISM IN Mn-Zn-O: A XANES ANALYSIS. *A. Quesada^{1,2}, F. Rubio Marcos⁴, M. García², J. Fernández⁴, F. Wilhelm³, A. Rogalev³, J. Llopis² and A. Hernando^{1,2}* *1. Institute of Applied Magnetism, Las Rozas, Madrid, Madrid, Spain; 2. Departamento Física de Materiales, Facultad de Ciencias Físicas. Universidad Complutense de Madrid, Madrid, Madrid, Spain; 3. ID12, European Synchrotron Radiation Facility, Grenoble, Isère, France; 4. Departamento de Cerámica, Instituto de Cerámica y Vidrio.CSIC., Cantoblanco, Madrid, Spain*

ER-08. Ferromagnetism in bulk Co-Zn-O. *E. Enríquez¹, A. Quesada^{1,2}, F. Rubio-Marcos³, L. Pérez¹, I. Lorite³, M. García¹, M. Martín-González⁴, J. Costa-Kramer⁴, S.C. Steplecaru⁴, J. Fernández³ and J. Llopis¹* *1. Dpt. Materials Science, Universidad Complutense de Madrid, Madrid, Madrid, Spain; 2. Institute for applied Magnetism, Universidad Complutense de Madrid, Las Rozas, Madrid, Spain; 3. Institute for Glass and Ceramics, CSIC, Madrid, Madrid, Spain; 4. Institute for Microelectronic, CSIC, Madrid, Madrid, Spain*

ER-09. Magnetism and Transport Properties of ZnO films doped with Co or Mn and Al. *G. Gehring¹, A.J. Behan¹, A. Mokhtari¹, H.J. Blythe¹, D. Score¹, J.R. Neal¹ and M. Fox¹* *1. Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom*

ER-10. Ferromagnetism of manganese-doped indium tin oxide films deposited on flexible polymer substrates. *T. Nakamura¹, K. Tanabe¹, S. Isozaki¹ and K. Tachibana¹* *1. Department of Electronic Science and Engineering, Kyoto University, Kyoto, Japan*

Session ES
RECORDING HEADS
(POSTER SESSION)
Robert Lamberton, Chair

ES-01. Fabrication of shielded planar type single-pole head. *K. Ise¹, T. Kiya¹, K. Taguchi¹ and K. Yamakawa¹* *1. AIT, Akita Prefectural R&D Center, Akita, Japan*

ES-02. New Type Side Shield Head for Ultra High Density Recording. *Y. Kim¹, S. Kukhyun¹ and K. Na¹* *1. HDD Core Tech TF, SAIT(Samsung Advanced Institute of Technology), Yongin-Si, Gyeonggi-Do, South Korea*

ES-03. Optimal Side Shield Write Head Design for Ultra High Recording Density. *Y. Kim¹, S. Kukhyun¹ and K. Shin¹* *1. HDD Core Tech TF, SAIT(Samsung Advanced Institute of Technology), Yongin-Si, Gyeonggi-Do, South Korea*

ES-04. Magnetic 1/f noise in MgO tunneling magnetoresistive sensors. *N. Smith¹, D. Mauri¹, J.A. Katine¹ and Y. Hong¹* *1. Hitachi Global Storage Technologies, San Jose, CA*

ES-05. Proposal of new method to fabricate nano-contacts in CoFe-NOL. *Y. Shiokawa¹, Y. Saki¹, S. Kawasaki¹, M. Doi¹ and M. Sahashi¹* *1. Electronic Engineering, Tohoku univ., Sendai, Japan*

ES-06. Effect of Spin Transfer Torque on 1/f Noise in TMR Heads. *J. Masuko¹, H. Akimoto¹, H. Kanai¹ and Y. Uehara¹* *1. Fujitsu Limited, Nagano, Japan*

ES-07. The role of pre-oxidation on the interface structure of Co/MgO multilayers. *D.S. Eastwood¹, W.F. Egelhoff, Jr.² and B.K. Tanner¹. 1. Physics, Durham University, Durham, United Kingdom; 2. National Institute of Standards and Technology, Gaithersburg, MD*

ES-08. Hard bias effect on magnetic noise in different types of tunnel magnetoresistive heads. *G. Han¹, B. Zong¹, P. Luo¹ and Z. Guo¹. 1. Data Storage Institute, A*STAR, Singapore, Singapore*

ES-09. Effect of annealing and barrier thickness on MgO-based Co/Pt and Co/Pd multilayered perpendicular magnetic tunnel junctions. *L. Ye¹, C. Lee^{1,2}, J. Syu^{1,3}, Y. Wang¹, K. Lin⁴, Y. Chang⁴ and T. Wu^{1,2}. 1. Taiwan SPIN Research Center, National Yunlin University of Science and Technology, Douliou, Taiwan; 2. Graduate School of materials science, National Yunlin University of Science and Technology, Douliou, Taiwan; 3. Graduate School of Optoelectronics, National Yunlin University of Science and Technology, Douliou, Taiwan; 4. Laser Application Technology Center, Industrial Technology Research Institute, Tainan, Taiwan*

ES-10. Effects of Current-Confined-Path on the Spin-Torque Noise in CPP-GMR Heads with a Current-Screen Layer. *M. Shiimoto¹, H. Katada¹, K. Nakamoto¹ and H. Hoshiya¹. 1. Central research laboratory, Hitachi, Ltd., Odawara-shi, Kanagawa-ken, Japan*

ES-11. Electrical 1/f noise in CPP-GMR with current-confined-pass nano-oxide layer. *M. Shimizu¹, M. Takagishi¹, M. Takashita¹ and H. Iwasaki¹. 1. Corporate Research & Development Center, Toshiba corporation, Kawasaki, Japan*

ES-12. Dependence of Thermal Stability on Cap Layer and Top Lead for Current Screen CPP-GMR Sensor. *K. Hoshino¹, H. Hoshiya¹ and Y. Sato¹. 1. Storage Technology Research Center, Central Research Laboratory, Hitachi, Ltd., Odawara-shi, Japan*

ET-04. Multiferroic properties of spin-spray deposited Ni_{0.23}Co_{0.13}Fe_{2.64}O₄ ferrite film on PZT substrate. *M. Liu¹, O. Obi¹, J. Lou¹, S. Stoute¹, Y. Chen¹, V.G. Harris¹ and N.X. Sun¹. 1. Electrical and Computer engineering, Northeastern University, Boston, MA*

ET-05. Stress and magneto-elastic properties control of amorphous Fe₈₀B₂₀ thin films during triode sputtering deposition. *I. Fernández-Martínez¹, J.L. Costa-Krämer¹ and F. Briones¹. 1. Inst. Microelectronica Madrid, CNM-CSIC, Tres Cantos, Spain*

ET-06. Poisson ratio of amorphous nanoporous alumina as determined from thermal expansion of Ni nanowires at low temperatures. *C.A. Ramos¹, E. Vassallo Brigneti¹, S. García² and M. Vázquez². 1. Centro Atómico Bariloche and Insituto Balseiro, Comisión Nacional de Energía Atómica and Universidad Nacional de Cuyo, S. C. de Bariloche, Rio Negro, Argentina; 2. Instituto de Ciencias de Materiales, CSIC, Madrid, Spain*

ET-07. Customizing the magnetic properties of magnetostrictive amorphous (Fe₈₀Co₂₀)₈₀B₂₀ multilayers with orthogonal anisotropies by using different buffer layers to control the induced-deposition stress. *M. González-Guerrero¹, J. Prieto², P. Sánchez¹ and C. Aroca¹. 1. Física Aplicada, ETSI Telecomunicación UPM, Madrid, Madrid, Spain; 2. ISOM, Universidad Politécnica de Madrid, Madrid, Madrid, Spain*

ET-08. Low Temperature Magnetoelastic Effects In Template Grown Ferromagnetic Nanowires. *J. De La Torre Medina¹, M. Darques¹ and L. Piraux¹. 1. Université Catholique de Louvain, Louvain-la-Neuve, Bravant Wallon, Belgium*

ET-09. Magnetostriction of Fe-Ti alloys. *C. Bormio-Nunes¹, A.B. Belarmino¹, C.T. Santos¹, V.C. Ugeda¹, L. Ghivelder² and C.A. Baldan¹. 1. Escola de Engenharia de Materiais, Universidade de Sao Paulo, Lorena, Sao Paulo, Brazil; 2. Instituto de Fisica, UFRJ, Rio de Janeiro, RJ, Brazil*

Session EU
FERRITE DYNAMICS AND APPLICATIONS
(POSTER SESSION)
Patrick Queffelec, Chair

EU-01. Picosecond magnetization dynamics of single-crystal Fe₃O₄ thin films. *C. Bunce¹, J. Wu¹, R. Chantrell¹, Y. Lu² and Y. Xu². 1. Department of Physics, University of York, York, United Kingdom; 2. Electronics, University of York, York, United Kingdom*

EU-03. Deconvolution of the ferromagnetic resonance absorption through the Verwey transition of magnetite. *H. Montiel¹, G. Alvarez², R. Valenzuela² and R. Zamorano³. 1. Tecnociencia, CCADET-UNAM, Mexico DF, Mexico DF, Mexico; 2. Metalicos y Ceramicos, IIM-UNAM, Mexico D.F., Mexico, D.F., Mexico; 3. Fisica, ESFM-IPN, Mexico D.F., Mexico, D.F., Mexico*

lxxvii

EU-04. Dynamic Magnetic Properties of NiFe₂O₄ Nanoparticles Embedded in SiO₂ Matrix. S. Mitra¹, K. Mandal¹ and E. Choi². *1. Materials Science, S. N. Bose National Centre for Basic Sciences, Kolkata, West Bengal, India; 2. National High Magnetic Field Laboratory, Tallahassee, FL*

EU-05. Analyzing the permeability and permittivity dispersion spectra of (Ni_{0.4}Zn_{0.59}Co_{0.01}) Fe_{1.98}O₄ spinel ferrites with Fe deficiency. M. Han¹ and L. Deng¹. *1. State Key Laboratory of Electronic Thin Films and Integrated Devices, University of Electronic Science and Technology of China, Chengdu, Sichuan, China*

EU-06. Magnetic and Microwave properties Sm-doped SrFe₁₂O₁₉ single crystals. J. Jalli^{1,2}, Y. Hong^{1,2}, S. Gee^{1,3}, J. Lee^{1,2}, S. Bae^{1,2}, G.S. Abo^{1,2}, A. Lyle^{1,2}, H. Han^{1,2}, J. Kim⁴, H. Lee⁴ and S. Lee⁴. *1. Electrical and Computer Engineering, University of Alabama, Tuscaloosa, AL; 2. MINT Center, University of Alabama, Tuscaloosa, AL; 3. Seagate Technology, Bloomington, MN; 4. Pohang Superconductivity Center, Pohang University of Science and Technology, Pohang, South Korea*

EU-07. Relaxation Effect of NiCr_{1.8}In_{0.1}Fe_{0.1}O₄ with Magnetic Anisotropy. S. Park¹, D. Choi¹ and C. Kim¹. *1. Department of Physics, Kookmin University, Seoul, South Korea*

EU-08. Temperature dependence of magnetic losses in soft ferrites. F. Fiorillo¹, C. Beatrice¹ and L. Zhemchuzhna¹. *1. Istituto Nazionale di Ricerca Metrologica INRIM, Torino, Italy*

EU-09. Suppression of GHz noise emitted from a four-layered PWB with a ferrite-plated inner ground layer. S. Yoshida¹, K. Kondo¹ and T. Kubodera². *1. NEC TOKIN Corporation, Sendai Miyagi, Japan; 2. System Design Laboratory Co., Ltd., Ebina Kanagawa, Japan*

EU-10. Fabrication of novel chip temperature sensing device using Mn substituted Li-Zn-Cu ferrite. M. Naoe¹, M. Oishi¹, S. Okazaki¹, T. Sato¹, K. Yamasawa¹ and Y. Miura¹. *1. Spin Device Technology Center, Shinshu University, Nagano, Japan*

EU-11. Effect of Co-Z type ferrite on broadband antenna miniaturization. J. Choi¹, K. Moon¹, J. Kim¹ and I. Kim². *1. Metallurgy and materials engineering, Hanyang university, Ansan, South Korea; 2. Central R&D institute, Samsung eletro-mechanics Co. LTD., Suwon, South Korea*

EV-02. Magnetoelastic properties of Tb-Dy-Ho-Fe-Co alloys. I. Tereshina¹, G. Burkhanov¹, O. Chistyakov¹, S. Nikitin² and G. Politova². *1. Baikov Institute of Metallurgy and Material Science RAS, Moscow, Russian Federation; 2. Faculty of Physics, M.V. Lomonosov Moscow State University, Moscow, Russian Federation*

EV-03. Modeling of bimorph type cantilever for actuators. G. Yun^{1,2} and B. Narsu¹. *1. department of physics, inner mongolia university, Hohhot, inner mongolia, China; 2. department of physics, inner mongolia normal university, Hohhot, inner mongolia, China*

EV-04. Microstructure and magnetic properties of Fe-Ga composite. K. Perduta¹, S. Busbridge¹ and M. Nabialek². *1. School of Engineering, University of Brighton, Brighton, United Kingdom; 2. Institute of Physics, Czestochowa University of Technology, Czestochowa, Poland*

EV-05. Giant Magnetostriction on the Metamagnetic Transition of the Ho₅Ge₄ A.M. Pereira¹, P. Algarabel², C. Sacristan³, L. Morellon^{2,3}, C. Magen⁴, M.R. Ibarra^{2,3}, J.B. Sousa¹ and J.P. Araujo¹. *1. IFIMUP Faculdade de Ciências da Universidade do Porto, Porto, Portugal; 2. ICMA - Universidad de Zaragoza and Consejo Superior de Investigaciones Científicas, Zaragoza, Spain; 3. Instituto de Nanociencia de Aragón, Universidad de Zaragoza, Zaragoza, Spain; 4. Oak Ridge Natl Lab, High Temp Mat Lab, Oak Ridge, TN*

EV-06. Voltage controlled magnetic properties of polycrystalline Terfenol-D film on PMN-PT single crystal substrate. J. Kim¹, V. Ravindranath¹ and S. Shin¹. *1. Physics, KAIST, Daejeon, South Korea*

EV-07. Study of giant magnetostrictive acceleration sensors. R. Yan¹, Q. Yang¹, W. Yang¹, S. Hou^{1,2}, F. Liu¹ and W. Yan¹. *1. Hebei University of Technology, Tianjin, China; 2. Tianjin University of Commerce, Tianjin, China*

EV-08. Influence of the magnetic anisotropy on the magnetic entropy change of Ni₂MnGa memory shape alloy. J.C. Leitão¹, D. Rocco¹, J. Amaral¹, M. Reis¹, V. Amaral¹, N. Martins² and P. Tavares². *1. Physics, Universidade de Aveiro, Aveiro, Portugal; 2. Chemistry, Universidade de Trás-os-Montes e Alto Douro, Vila Real, Vila Real, Portugal*

EV-09. Coincidence of magnetic and martensitic transition in NiMnGa thin films obtained by changing growth parameters. F. Albertini¹, F. Casoli¹, S. Fabbri¹, L. Righi², V.A. Chernenko³, S. Besseghini³ and A. Gambardella³. *1. IMEM-CNR, Parma, Italy; 2. Dipartimento Chimica GIAF, Università di Parma, Parma, Italy; 3. IENI – CNR, Lecco, Italy*

EV-10. MFM domain imaging of textured Ni-Mn-Ga/substrate thin film composites. R. Lopez Anton^{1,2}, V. Chernenko³, J. Barandiaran⁴, I. Orue⁴, S. Besseghini³, M. Ohtsuka⁵ and A. Gambardella³. *1. ISIS, STFC Rutherford Appleton Laboratory, Didcot, United Kingdom; 2. ICMA, CSIC-Universidad de Zaragoza, Zaragoza, Spain; 3. CNR-IENI, Lecco, Italy; 4. Universidad del Pais Vasco, Bilbao, Spain; 5. IMRAM, Tohoku University, Sendai, Japan*

Session EW
**MULTIFERROICS, FERRITES AND OTHER MATERIALS
(POSTER SESSION)**

Aria Yang, Chair

EW-01. Substrate dependent structure and magnetic properties in HoMnO₃ films. *T. Han¹ and J. Lin²1. Department of Applied Physics, National University of Kaohsiung, Kaohsiung, Taiwan; 2. Center for Condensed Matter Sciences, National Taiwan University, Taipei, Taiwan*

EW-02. Effect of iron-doping on the structural and magnetic properties of LuMnO₃. *J. Lin¹ and T. Han²1. Center for Condensed Matter Sciences, National Taiwan University, Taipei, Taiwan; 2. Department of Applied Physics, National University of Kaohsiung, Kaohsiung, Taiwan*

EW-03. Magnetic hysteresis in ErFeO₃ near the 4.1 K ordering transition. *L.T. Tsymbal¹, Y.B. Bazaliy^{2,3}, G.N. Kakazei^{3,4}, F.J. Palomares⁴ and P.E. Wigen⁵1. O. Galkin Donetsk Physics and Technology Institute, Donetsk, Ukraine; 2. University of South Carolina, Columbia, SC; 3. Institute of Magnetism, National Academy of Science, Kyiv, Ukraine; 4. Instituto de Ciencia de Materiales de Madrid, Madrid, Spain; 5. Ohio State University, Columbus, OH*

EW-04. Mössbauer studies of ⁵⁷Fe-doped in LiCoPO₄ at low temperatures. *S. Moon¹ and C. Kim¹1. Department of Physics, Kookmin University, Seoul, South Korea*

EW-05. Effects of gallium distribution on terbium bismuth gallium iron garnet. *I. Park¹ and C. Kim¹1. Physics, Kookmin University, Seoul, South Korea*

EW-06. Physical properties of Fe_{3-x}Mg_xO₄ ferrite films on MgO(001) and SrTiO₃(001) grown by molecular beam epitaxy. *D. Lee¹ and G. Chern²1. Electrical Engineering Department, Da-Yeh University, Chang-Hua, Taiwan; 2. Physics, National Chung Cheng University, Chia-Yi, Taiwan*

EW-07. Enhancement of magnetoelastic properties of highly magnetostrictive cobalt ferrite through control of sintering conditions. *I. Nlebedim¹, N. Ranvah¹, A.J. Moses¹, D.C. Jiles¹, P.I. Williams¹, Y. Melikhov¹, J.E. Snyder¹ and F. Anayi¹1. Wolfson Centre for Magnetism, Cardiff School of Engineering, Cardiff, United Kingdom*

EW-08. Comparative study of the microstructural and magnetic properties of cobalt ferrites synthesized by ceramic and oxidation wet methods. *M. Feder², L. Diamandescu², I. Bibicu², O.F. Caltun¹, I. Dumitru¹, L. Boutiuc Hrib¹, H. Chiriac³, N. Lupu³, M. Vilceanu⁴ and V. Vilceanu⁴1. Physics, Al. I. Cuza University, Iasi, Romania; 2. National Institute of Materials Physics, Bucharest-Magurele, Romania; 3. National Institute of R&D for Technical Physics, Iasi, Romania; 4. AferoExim Ltd., Buharest, Romania*

EW-09. Nonequilibrium cation influence on the Néel temperature in ZnFe₂O₄. *I. Al-Omari¹, H.M. Widadallah¹, F.R. Sives² and S.J. Stewart^{1,2}1. Physics, Sultan Qaboos University, Muscat, Oman; 2. IFLP-CONICET and Departamento de Física, Universidad Nacional de La Plata, La Plata, Argentina*

INTERMAG 2008

EW-10. Synthesis and magnetic properties of surface coated magnetite superparamagnetic nanoparticles. *K. Kim¹, M. Kim², Y. Choa², Y. Cha¹, T. Hwang¹ and D. Kim¹1. Dept. of Physics, Yeungnam University, Gyeongsan, South Korea; 2. Dept. of Chemical Engineering, Hanyang University, Ansan, South Korea*

EW-11. Magnetic properties of Hf_{1-x}R_xFe₆Ge₆ compounds. *J. Rubin¹, C. Piquer¹, N. Plugaru¹, J. Bartolomé¹ and F. Grandjean²1. Instituto de Ciencia de Materiales de Aragón, 50009 Zaragoza, Spain; 2. Dept. of Physics, Université de Liège, B-4000 Sart-Tilman, Belgium*

EW-12. Mössbauer study of iron sulfide nano-compound. *S. Hyun¹, I. Shim¹ and C. Kim¹1. Physics, Kookmin University, SEOUL, South Korea*

EW-13. Preparation of Metal-Polymer composite films by metal- polymer co-electrodeposition method. *N. Fujita¹, M. Matsuba¹, Y. Toujou¹, T. Kazuya¹, N. Satoru¹, I. Masanobu² and I. Mitsuteru²1. Nara National College of Technology, Yamatokoriyama, Japan; 2. Toyohashi University of Technology, Toyohashi, Japan*

EW-14. Nonlinear homogenisation technique for saturable soft magnetic composites. *O. Bottauscio¹, M. Codegone³, V. Chiado¹ Piat³, M. Chiampì² and A. Manzin¹1. Electromagnetics, Istituto Nazionale di Ricerca Metrologica, Torino, Italy; 2. Dip. Ingegneria Elettrica, Politecnico di Torino, Torino, Italy; 3. Dip. Matematica, Politecnico di Torino, Torino, Italy*

EW-15. Structural and magnetic properties of nanocrystalline strontium hexaferrite prepared by an ionic reaction technique. *J. Araujo¹, F. Cabral^{1,4}, J. Soares², M. Ginani³, F. Machado⁴ and J. Cunha⁵1. Departamento de Física Teórica e Experimental, Universidade Federal do Rio Grande do Norte, Natal, Rio Grande do Norte, Brazil; 2. Departamento de Física, Universidade do Estado do Rio Grande do Norte, Mossoró, Rio Grande do Norte, Brazil; 3. Departamento de Química, Universidade Federal do Rio Grande do Norte, Natal, Rio Grande do Norte, Brazil; 4. Departamento de Física, Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil; 5. Instituto de Física, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil*

Session EX
**MAGNETIC TUNNEL JUNCTIONS -II
(POSTER SESSION)**

Berthold Ocker, Chair

EX-01. Tunnel spin-polarization of low-work-function ferromagnets. *R. Patel¹, B. Min¹, S. Dash¹, M. de Jong¹ and R. Jansen¹1. MESA+ Institute for Nanotechnology, University of Twente, Enschede, Netherlands*

EX-02. Strain dependence of magnetoresistance in magnetostrictive magnetic tunnel junctions. *J.G. Deak¹1. Advanced Technology, NVE Corporation, Eden Prairie, MN*

lxxix

EX-03. Broadband Ferromagnetic Resonance Linewidth Measurements of Magnetic Tunnel Junction Multilayers. *J. Sierra*¹, F. Aliev¹, R. Heindl², S. Russek² and W. Rippard². *1. Condensed Matter Physics, UAM, Madrid, Spain; 2. NIST, Boulder, CO*

EX-04. Effect of interface roughness on magnetoresistance and magnetization switching in magnetic tunnel junction. *B. Chun*¹, M. Coey¹, S. Lee², J. Hwang², J. Rhee², H. Yim², T. Kim³, Y. Kim⁴ and Y. Kim⁴. *1. School of Physics, Trinity College, Dublin, Ireland; 2. Department of Physics, Sookmyung Women's University, Seoul, South Korea; 3. Nanotechnology and Advanced Materials Engineering, Sejong University, Seoul, South Korea; 4. Department of Materials Science and Engineering, Korea University, Seoul, South Korea*

EX-05. Appearance of a tunneling spectrum peak by electrical breakdown of tunneling junction. *K. Horikiri*¹ and K. Shiiki¹. *1. Applied Physics and Physico-Informatics, Keio University, Yokohama, Kanagawa, Japan*

EX-06. Magnetostriction and tunneling magnetoresistance of Co/AlOx/Co/IrMn junctions. *Y. Chen*^{1,2}, S. Jen^{1,2} and Y. Yao^{2,1}. *1. Institute of Physics, Academia Sinica, Institute of Physics, Taipei, Taiwan; 2. Department of Materials Engineering, Department of Materials Engineering, Tatung University, Taipei, Taiwan*

EX-07. Magneto-transport in a single nano-object with a conductive AFM. *P. Zermatten*¹, *G. Gaudin*¹ and *A. Schuhl*¹. *1. SPINTEC, CEA/CNRS, Grenoble, France*

EX-08. Huge electron mean free path in MgO - Detection of the valence band in buried Co₂MnSi-MgO half-metallic ferromagnetic tunnel junctions by means of photo emission spectroscopy. *B. Balke*¹, G.H. Fecher¹, A. Gloskowskii¹, S. Ouardi¹, C. Felser¹ and M. Yamamoto². *1. University Mainz, Mainz, Germany; 2. Graduate School of Informatic Science and Technology, Hokkaido University, Sapporo, Japan*

EX-09. X-ray magnetic dichroism studies of half-metallic Heusler alloys and magnetic tunnel junctions. *N.D. Telling*¹, P.S. Keatley², G. van der Laan^{1,5}, R.J. Hicken², E. Arenholz³, Y. Sakuraba⁴, M. Oogane⁴, Y. Ando⁴ and T. Miyazaki⁴. *1. Magnetic Spectroscopy Group, STFC Daresbury Laboratory, Warrington, United Kingdom; 2. School of Physics, University of Exeter, Exeter, United Kingdom; 3. Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA; 4. Department of Applied Physics, Tohoku University, Aoba-yama 6-6-05, Japan; 5. Diamond Light Source Ltd, Harwell Science and Innovation Campus, Didcot, Oxfordshire, United Kingdom*

EX-10. Fabrication of magnetic tunnel junctions with Co₂FeSi Heusler alloy and MgO crystalline barrier. *W. Lim*¹, G. Choi¹ and T. Lee¹. *1. Department of Materials Science and Engineering, KAIST, Daejeon, South Korea*

EX-11. (110) manganite electrodes for magnetic tunnel junctions. *I.C. Infante*¹, F. Sánchez¹, J. Fontcuberta¹, S. Fusil², K. Bouzehouane², G. Herranz² and A. Barthélémy². *1. Magnetic Materials and their Applications, Institut de Ciència de Materials de Barcelona, Bellaterra, Barcelona, Spain; 2. Unité Mixte de Physique CNRS/Thales, Orsay, France*

EX-12. Magneto-transport characteristics of magnetic tunnel junction with a synthetic antiferromagnetic amorphous CoFeSiB free-layer. *B. Chun*¹, M. Coey¹, S. Lee², J. Hwang², J. Rhee², H. Yim², T. Kim³ and Y. Kim⁴. *1. School of Physics, Trinity College, Dublin, Ireland; 2. Department of Physics, Sookmyung Women's University, Seoul, South Korea; 3. Nanotechnology and Advanced Materials Engineering, Sejong University, Seoul, South Korea; 4. Department of Materials Science and Engineering, Korea University, Seoul, South Korea*

EX-13. Structure and magnetic properties of epitaxial full-Heusler alloy Co₂FeAl_{0.5}Si_{0.5} films on MgO-buffered MgO (001) substrates and TMR using their electrodes. *H. Sukegawa*^{1,2}, W. Wang², R. Shan² and K. Inomata². *1. International Center for Young Scientists (ICYS), National Institute for Materials Science (NIMS), Tsukuba, Japan; 2. Magnetic Material Center, National Institute for Materials Science (NIMS), Tsukuba, Japan*

EX-14. Coherent effects for electronic equilibrium and transport in perfect magnetic junctions. *Y.G. Pogorelov*¹ and H.G. Silva^{2,1}. *1. IFIMUP/IN, Universidade do Porto, Porto, Portugal; 2. CEOT, Universidade do Algarve, Faro, Algarve, Portugal*

EX-15. Spin Transport in a Double Magnetic Tunnel Junction Quantum Dot System with Noncollinear Magnetization. *M. Ma*¹ and M. Jalil¹. *1. Department of Electrical and Computer Engineering, Information Storage Materials Laboratory, Singapore, Singapore*

**WEDNESDAY
AFTERNOON
2:30**

AUDITORIO A

**Session FA
SYMPOSIUM ON SPIN TORQUE TRANSFER FOR MRAM**
J. Wang, Chair

2:30

FA-01. Spin torque effects in magnetic nanostructures. (Invited) *R. Buhrman*¹. *1. Cornell University, Ithaca, NY*

3:00

FA-02. The development of magnetic tunnel junction memory: from first devices to Mbit MRAMs to emerging spin-torque transfer MRAMs. (Invited) *W.J. Gallagher*¹. *1. IBM Watson Research Center, Yorktown Heights, NY*

3:30

FA-03. Spin torque devices for high density MRAM and nano-oscillators. (Invited) *N.D. Rizzo*¹, R.W. Dave¹, F.B. Mancoff¹, P.G. Mather¹, B. Butcher¹ and S. Tehrani¹. *1. Technology Solutions Organization, Freescale Semiconductor, Chandler, AZ*

4:00

3:30

FA-04. Spin Torque Transfer Switching of Perpendicular Magnetoresistive elements for High Density MRAMs. (Invited) *H. Yoda*¹, *T. Kishi*¹, *T. Kai*¹, *T. Nagase*¹, *M. Yoshikawa*¹, *M. Nakayama*¹, *E. Kitagawa*¹, *M. Amano*¹, *H. Aikawa*¹, *N. Shimomura*¹, *K. Nishiyama*¹, *T. Daibou*¹, *S. Takahashi*¹, *S. Ikegawa*¹, *K. Yakushiji*², *T. Nagahama*², *H. Kubota*², *A. Fukushima*², *S. Yuasa*², *Y. Nakatani*³, *M. Oogane*⁴, *Y. Ando*⁴, *Y. Suzuki*^{5,2}, *K. Ando*² and *T. Miyazaki*⁶ *1. Corporate R & D center, Toshiba, Kawasaki, Japan; 2. Nanoelectronics Research Institute, AIST, Tsukuba, Japan; 3. Computer Science, The University of Electro-Communications, Tokyo, Japan; 4. Applied Physics, Tohoku University, Sendai, Japan; 5. Materials Engineering Science, Osaka University, Osaka, Japan; 6. WPI Advanced Institute for Materials Research, Tohoku University, Sendai, Japan*

FB-04. Spin Coulomb Drag: a Limitation for Spintronics? (Invited) *I. D'Amico*¹ and *C.A. Ullrich*² *1. Physics, University of York, York, United Kingdom; 2. Physics and Astronomy, University of Missouri-Columbia, Columbia, MO*

4:00

FB-05. Organic spintronics: on the spin injection at the CuPc/GaAs interface. *M. Cinchetti*¹, *H. Ding*², *Y. Gao*², *J. Wüstenberg*¹, *M. Sánchez Albaneda*¹, *O. Andreyev*¹, *M. Bauer*¹ and *M. Aeschlimann*¹ *1. Department of Physics, University of Kaiserslautern, Kaiserslautern, Germany; 2. Department of Physics and Astronomy, University of Rochester, Rochester, NY*

WEDNESDAY
AFTERNOON
2:30

3:00

2:30

FB-02. Electrical Generation, Modulation and Detection of Spin Currents in Silicon in a Lateral Transport Geometry. *B. Jonker*¹, *O. van 't Erve*¹, *G. Kioseoglou*¹, *A. Hanbicki*¹, *C. Awo-Affouda*¹, *M. Holub*¹, *C. Li*¹ and *P. Thompson*¹ *1. Naval Research Laboratory, Washington, DC*

FC-01. High sensitivity spin valve sensors with antiferromagnetically coupled flux guides. *I.G. Trindade*^{1,2}, *J. Oliveira*², *J. Teixeira*², *J.B. Sousa*^{1,2}, *P.P. Freitas*³, *S. Cardoso*³ and *R.C. Chaves*³ *1. Physics, Faculdade de Ciências da Universidade do Porto, Porto, Portugal; 2. IFIMUP-IN, Porto, Portugal; 3. INESC-MN-IN, Lisboa, Portugal*

3:15

2:45

FB-03. Electrical transport properties of MgO/ferromagnet contacts to p-Si for spin injection and detection. *T. Dimopoulos*¹, *T. Uhrmann*¹, *D. Schwarz*¹, *V. Lazarov*², *D. Kirk*², *A. Kohn*², *S. Weyers*³, *U. Paschen*³ and *H. Brückl*¹ *1. Nano-System-Technologies, Austrian Research Centers GmbH - ARC, Vienna, Austria; 2. Department of Materials, University of Oxford, Oxford, United Kingdom; 3. Microelectronic Circuits and Systems, Fraunhofer Institute, Duisburg, Germany*

FC-02. Gate Controlled Magnetoresistance in a Ballistic Nanodevice. *S. Kumar*^{1,2}, *S. Tan*¹ and *M. Jali*^{1,2} *1. SMI, Data Storage Institute, Singapore, Singapore; 2. ISML, ECE, National University of Singapore, Singapore, Singapore*

3:00

FC-03. Magnetic-tunnel-junction-based programmable logic devices by spin transfer torque switching. X. Yao¹, Y. Zhang¹, H. Meng¹ and J. Wang¹ *1. MINT Center & Electrical and Computer Engineering Department, Univ. Of Minnesota, Minneapolis,, MN*

3:15

FC-04. Transport properties of fully epitaxial magnetic tunnel transistor with a MgO barrier. T. Nagahama¹, H. Saito^{1,2} and S. Yuasa¹ *1. AIST, Tsukuba, Ibaraki, Japan; 2. PRESTO, Japan Science and Technology Agency, Kawaguchi, Saitama, Japan*

3:30

FC-05. A Planar Magnetic Content Addressable Memory Cell. W. Wang¹ and Z. Jiang¹ *1. Electrical Engineering, University of Wisconsin - Milwaukee, Milwaukee, WI*

3:45

FC-06. Investigation on Magneto-Optoelectronic properties in Metal/Organic Heterostructure Films. N. Lee¹, T. Kim¹, J. Lee², H. Cho³ and C. Lee³ *1. Department of Physics, Ewha Womans University, Seoul, South Korea; 2. Microgate, Inc., Anyang, South Korea; 3. School of Electrical Engineering & Computer Science, Seoul National University, Seoul, South Korea*

4:00

FC-07. Electrical switching controlled by magnetic field. J. Lee¹, S. Joo^{1,4}, T. Kim¹, J. Hong^{1,4}, K. Rhie^{1,4}, B. Lee², T. Kim³ and K. Shin⁴ *1. Applied Physics, Korea University, Chochiwon, South Korea; 2. Physics, Inha University, Incheon, South Korea; 3. Physics, Pohang University of Science and Technology, Pohang, South Korea; 4. Korea Institute of Science and Technology, Seoul, South Korea*

4:15

FC-08. Micromagnetic Investigation of Interaction between Spin-Polarized Current and Spin-wave. S. Seo¹ and K. Lee¹ *1. Korea University, Seoul, South Korea*

WEDNESDAY
AFTERNOON
2:30

PARIS

Session FD
MAGNETIC OXIDES & HEUSLER ALLOYS II
Jacobo Santamaria, Chair

2:30

FD-01. Ferromagnetic oxides for spin filtering. (Invited) J. Fontcuberta¹, A. Barthelemy², M. Bibes², U. Lüders¹, M. Gajec², K. Bouzehouane², J.F. Bobo³, S. Fusil², E. Jacquet², J.P. Contour², A. Fert², F. Sánchez¹, X. Martí¹, F. Rigato¹, V. Laukhin¹, V. Skumryev¹ and M. Varela⁴ *1. ICMA-B-CSIC, Bellaterra, Spain; 2. Unité Mixte de Physique CNRS-Thales,, Palaiseau, France; 3. Lab. de Nanomagnétisme pour l'Hyperfréquence CNRS-ONERA, Toulouse, France; 4. Dept. Física Aplicada i Òptica. U. Barcelona, Barcelona, Spain*

3:00

FD-02. Giant planar Hall effect in epitaxial Fe₃O₄ thin films and its temperature dependence. J.M. De Teresa¹, A. Fernandez-Pacheco^{1,2}, J. Orna², L. Morellon^{1,2}, P. Algarabel¹, J.A. Pardo^{2,3} and R. Ibarra^{1,2} *1. Instituto de Ciencia de materiales de Aragon, CSIC-University of Zaragoza, Zaragoza, Spain; 2. Instituto de Nanociencia de Aragon, University of Zaragoza, Zaragoza, Spain; 3. Departamento de Ciencia y Tecnología de Materiales y Fluidos, University of Zaragoza, Zaragoza, Spain*

3:15

FD-03. Time resolved precessional magnetization dynamics in Fe₃O₄ thin films measured by pulsed inductive microwave magnetometry. S. Serrano-Guisan¹, C. Boothman², M. Abid², J.D. Coey² and H.W. Schumacher¹ *1. Physikalisch-Technische Bundesanstalt, Braunschweig, Germany; 2. CRANN and School of Physics, Trinity College, Dublin, Ireland*

3:30

FD-04. Angular dependence of the magnetoresistance measured across a single-grain boundary. L.B. Steren¹, G. Alejandro¹, J.C. Rojas Sanchez¹, E.N. Monteblanco Vences¹ and H. Pastoriza¹ *1. Physics, Centro Atomico Bariloche, S.C. Bariloche, Rio Negro, Argentina*

3:45

FD-05. Antiferromagnetic Heusler compounds with high spin-polarization. G. Liu¹, X. Dai¹, G. Fecher¹ and C. Felser¹ *1. Institution for Inorganic and Analytical Chemistry, Johannes Gutenberg University of Mainz, Mainz, Germany*

4:00

FD-06. Exchange constant and magnetic anisotropy in Co₂-based Heusler compounds. *J. Hamrle¹, O. Gaier¹, B. Hillebrands¹, M. Jourdan², H. Schneider², G. Jakob², T. Kubota³, Y. Sakuraba³, M. Oogane³, Y. Ando³ and C. Felser⁴* *1. Fachbereich Physik, Technische Universität Kaiserslautern, Kaiserslautern, Germany; 2. Institut für Physik, Johannes-Gutenberg-Universität, Mainz, Germany; 3. Department of Applied Physics, Graduate School of Engineering, Tohoku University, Sendai, Japan; 4. Institute of Inorganic and Analytical Chemistry, Johannes-Gutenberg-Universität, Mainz, Germany*

4:15

FD-07. Spin transitions in DyCoO₃ investigated by measuring the electric quadrupole interactions. *F.H. Cavalcante¹, A.W. Carbonari¹, G.A. Cabrera-Pasca¹, J. Mestnik-Filho¹ and R.N. Saxena¹* *1. CRPq, IPEN, Sao Paulo, Sao Paulo, Brazil*

**WEDNESDAY
AFTERNOON
2:30**

LONDRES

Session FE LIFE SCIENCE AND APPLICATIONS II

Angel Millan, Chair

2:30

FE-01. Prototyping and Evaluation of Magnetic Communication Coils between Inside and Outside of Body for Controlling FES. *K. Kato¹, M. Goto¹, K. Sugano¹, M. Miyashita¹, F. Sato¹, H. Matsuki¹, Y. Handa² and T. Sato³* *1. Department of Electrical and Communication Engineering, Graduate School of Engineering, Tohoku University, Sendai, Miyagi, Japan; 2. Graduate School of Medicine, Tohoku University, Sendai, Japan; 3. NEC TOKIN Corp., Sendai, Japan*

2:45

FE-02. Bone Tissue Engineering using Magnetically Oriented Collagen. *T. Shinohara¹, T. Saito², D. Saito¹, A. Nakahira³, M. Aoki⁴ and M. Kotani²* *1. Research Institute for Advanced Technologies, Tokyo Denki University, Inzai-shi, Chiba Pref., Japan; 2. Graduate School of Engineering, Tokyo Deki University, Kanda, Tokyo, Japan; 3. Graduate School of Engineering, Osaka Prefecture University, Sakai, Japan; 4. Neomax, Hitachi Metals, Ltd, Oomachichou, Saga Pref., Japan*

3:00

FE-03. Modification of motor evoked potentials caused by electrical peripheral nerve stimulation in transcranial magnetic stimulation. *O. Hiwaki¹, M. Odagaki¹, F. Hiroshi¹, A. Kodabashi² and T. Fujimoto²* *1. Graduate School of Information Sciences, Hiroshima City University, Hiroshima, Japan; 2. Fujimoto Hayasuzu Hospital, Miyakonojyo, Japan*

3:15

FE-04. Detection of the terrestrial magnetism in migrating birds: Is it a question of vision? *S. Migalski^{1,2}, T. Meydan², J.T. Erichsen¹ and V.P. Bingman³* *1. Optometry and Vision Sciences, Cardiff University, Cardiff, United Kingdom; 2. Engineering, Cardiff University, Cardiff, United Kingdom; 3. Psychology, Bowling Green State University, Bowling Green, OH*

3:30

FE-05. Computation of Current Distribution in Rat Head by Transcranial Magnetic Stimulation and Electroconvulsive Therapy. *M. Lu¹, S. Ueno², T. Thorlin³, P. Miranda¹ and M. Persson⁴* *1. Institute of Biophysics and Biomedical Engineering, Faculty of Sciences, University of Lisbon, Lisbon, Portugal; 2. Department of Applied Quantum Physics, Graduate School of Engineering, Kyushu University, Fukuoka, Japan; 3. Institute for Clinical Neuroscience, Sahlgrens University Hospital, Gothenburg, Sweden; 4. Department of Signals and Systems, Chalmers University of Technology, Gothenburg, Sweden*

3:45

FE-06. Spintronic biosensors based on Fe/MgO/Fe(001) tunnelling junctions. *R. Bertacco¹, S. Brivio¹, M. Cantoni¹, A. Cattoni¹ and D. Petti¹* *1. Center LNESS, Politecnico di Milano, Como, Italy*

4:00

FE-07. MTJ based biosensor with top Au electrodes and functionalization layers. *F.A. Cardoso^{1,2}, S. Cardoso^{1,2}, V.C. Martins^{1,3} and P.P. Freitas^{1,2}* *1. INESC-MN, Lisboa, Portugal; 2. Instituto Superior Tecnico, Lisboa, Portugal; 3. Center for Biological and Chemical Engineering (CEBQ), Lisboa, Portugal*

4:15

FE-08. Stem Cell Separator and Counter. *J. Loureiro^{1,2}, S. Cardoso^{1,2}, C.L. Silva^{2,3}, J.M. Cabral^{2,3} and P.P. Freitas^{1,2}* *1. INESC-Microsystems and Nanotechnologies, Lisbon, Portugal; 2. Instituto Superior Técnico (IST), Lisbon, Portugal; 3. CEBQ - IST, Lisbon, Portugal*

**WEDNESDAY
AFTERNOON
2:30**

BERLIN

Session FF MICROWAVE DEVICES AND FMR

Raul Valenzuela, Chair

2:30

FF-01. Experimental realization of spin-wave logic gates. *A.A. Serga¹, T. Schneider¹, B. Leven¹, B. Hillebrands¹, M.P. Kostylev² and R.L. Stamps²* *1. Fachbereich Physik und Forschungsschwerpunkt MINAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany; 2. School of Physics, University of Western Australia, Crawley, WA, Australia*

2:45

FF-02. Microwave signal processor based on spin waves in permalloy (Py) films. G.A. Melkov¹, Y.V. Koblyanskiy¹, R.A. Slipec¹, A.V. Talalaevskij¹ and A.N. Slavin². *1. Faculty of Radiophysics, Kiev National Taras Shevchenko University, Kiev, Ukraine; 2. Department of Physics, Oakland University, Rochester, MI*

3:00

FF-03. Design and optimization of one-dimensional YIG film based magnonic crystal. A. Chumak^{1,2}, A.A. Serga¹ and B. Hillebrands¹. *1. Fachbereich Physik und Forschungsschwerpunkt MINAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany; 2. Department of Radiophysics, Taras Shevchenko National University of Kiev, Kiev, Ukraine*

3:15

FF-04. Experimental Verification of Skin Effect Suppression in Multilayer Thin-Film Conductor Taking Advantage of Negative Permeability of Magnetic Film beyond FMR frequency. S. Shiozawa¹, Y. Shimada¹, M. Yamaguchi¹, K. Kim², Y. Zhuang³, M. Vroubel³ and B. Rejaei³. *1. Electrical and Communication Engineering, Tohoku University, Sendai, Japan; 2. Physics, Yeungnam University, Gyeongsan, South Korea; 3. Electronic Components, Technology, and Materials, Delft University of Technology, Delft, Netherlands*

3:30

FF-05. Selective excitation and imaging of precessional modes in soft-magnetic squares. A. Neudert¹, P.S. Keatley¹, V.V. Kruglyak¹, J. McCord² and R.J. Hicken¹. *1. School of Physics, University of Exeter, Exeter, United Kingdom; 2. Institute for Metallic Materials, IFW Dresden, Dresden, Germany*

3:45

FF-06. Electrically detected ferromagnetic resonance in electrodeposited spin valves under AC excitation. N. Biziere¹, E. Murè¹ and J. Ansermet¹. *1. Institut de Physique des nanostructures, Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland*

4:00

FF-07. Ferromagnetic resonance modes below the critical thickness of stripe domain formation. J. McCord¹, A. Gerber² and E. Quandt¹. *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany; 2. Institute for Inorganic Functional Materials, CAU Kiel, Kiel, Germany*

4:15

FF-08. Ferromagnetic resonance study of Fe/FePt coupled films with perpendicular anisotropy. D. Schmool¹, A. Apolinário¹, F. Casoli² and F. Albertini². *1. Physics, Universidade do Porto, Porto, Portugal; 2. IMEM, CNR, Parma, Italy*

WEDNESDAY
AFTERNOON
2:30

AMSTERDAM

Session FG

NANOSTRUCTURED HARD MAGNETIC MATERIALS - II

Oliver Gutfleisch, Chair

2:30

FG-01. Inter-phase exchange coupling in Sm(Co,Cu)₅/α-Fe nanocomposite obtained by mechanical milling and annealing. V. Pop^{1,2}, O. Isnard², D. Givord² and I. Chichinas³. *1. Faculty of Physics, Babes-Bolyai University, 400084 Cluj-Napoca, Romania, Cluj-Napoca, Romania; 2. Institut Néel, CNRS, associé à l'Université Joseph Fourier de Grenoble, BP166, 38042 Grenoble, Cedex 9, France, Grenoble, France; 3. Materials Sciences and Technology Dept., Technical University of Cluj-Napoca, 103-105 Muncii ave., 400641 Cluj-Napoca, Romania, Cluj-Napoca, Romania*

2:45

FG-02. Isotropic Sm_x(Co,Fe,Mn)_{100-x} Magnets Via High-Energy Ball Milling. A. Gabay¹, J. Liu² and G.C. Hadjipanayis¹. *1. University of Delaware, Newark, DE; 2. Electron Energy Corporation, Landisville, PA*

3:00

FG-03. Effect of TiC and Cr additions on magnetic properties of nanocrystalline (Pr,Nd)FeB alloys. V.C. de Franco², R.K. Murakami³, H.R. Rechenberg⁴, T. Yonamine¹, F.P. Missell^{1,2} and V. Villas-Boas². *1. Divisão de Metrologia de Materiais, INMETRO, Duque de Caxias, Rio de Janeiro, Brazil; 2. Centro de Ciências Exatas e Tecnologia, Universidade de Caxias do Sul, Caxias do Sul, Rio Grande do Sul, Brazil; 3. Universidade do ABC, Santo André, São Paulo, Brazil; 4. Instituto de Física, Universidade de São Paulo, São Paulo, São Paulo, Brazil*

3:15

FG-04. Two Major Effects of Process Temperature on the Characteristic of Bulk Nanostructured Nd-Fe-B / Fe-Co Composite Magnets. C.H. Chen¹, Y. Shen², M. Huang³ and A.K. Higgins¹. *1. University of Dayton Research Institute, Dayton, OH; 2. FutureTek Corp, Dayton, OH; 3. UES / Wright Patterson Air Force Base, Dayton, OH*

3:30

FG-05. Nd₂Fe₁₄B based Magnetic Nanocomposites Synthesized by Electrodeposition, Microemulsion and Melt Spinning Techniques. R. Ramanujan¹, Z. Liu¹, S. Viswanathan¹, P.K. Deheri¹ and S. Shukla¹. *1. School of Mater. Sci. Eng., Nanyang Tech. Univ., Singapore, Singapore*

3:45

FG-06. Improvement in Morphology and Magnetic Properties of Thick Nanocomposite Film-Magnets with Multi-Layered Structure. *H. Fukunaga*¹, H. Nakayama¹, M. Nakano¹, M. Ishimaru², M. Itakura² and F. Yamashita³ *1. Department of Electrical Engineering and Electronics, Nagasaki University, Nagasaki, Nagasaki, Japan; 2. Department of Applied Science for Electronics and Materials, Kyushu University, Kasuga, Fukuoka, Japan; 3. Matsushita Electric Industrial Co., Ltd., Daito, Osaka, Japan*

4:00

FG-07. Magnetic properties of Nd-Fe-B thin films with island structure prepared on Mo buffer layer. *T. Shima*¹, H. Kato¹ and T. Sato² *1. Faculty of Engineering, Tohoku Gakuin University, Tagajo, Japan; 2. Toyota Central R&D Labs., Nagakute, Japan*

4:15

FG-08. Highly Coercive Nanocrystalline Electro-Deposited CoPt Thin Films. *K. Zuzek Rozman*¹, J. Kovac², P.J. McGuinness¹ and S. Kobe¹ *1. Department for Nanostructured Materials, Jozef Stefan Institute, Ljubljana, Slovenia; 2. Department of Surface Engineering and Optoelectronics, Jozef Stefan Institute, Ljubljana, Slovenia*

WEDNESDAY
AFTERNOON
2:30

CARACAS

Session FH OXIDE MULTIFERROICS AND FERRITES

Yevgen Melikhov, Chair

2:30

FH-01. Magnetism and magnetocaloric effect in multiferroic LuFe₂O₄ *J. Gass*¹, N. Frey¹, M. Phan¹, H. Srikanth¹, M. Angst², B. Sales² and D. Mandrus² *1. Department of Physics, University of South Florida, Tampa, FL; 2. Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN*

2:45

FH-02. Design and processing of new ferrite materials from an atomistic perspective. *A. Yang*¹, A. Geiler¹, X. Zuo², C. Vittoria¹ and V.G. Harris¹ *1. Center for Microwave Magnetic Materials and Integrated Circuits, Electrical and Computer Engineering, Northeastern University, Boston, MA; 2. College of Information Technical Science, Nankai University, Tianjin, China*

3:00

FH-03. Texture analysis of ferrite materials by means of electron backscatter diffraction (EBSD). *A.D. Koblishka-Veneva*¹, M.R. Koblishka² and F. Muecklich¹ *1. Institute for Functional Materials, University of the Saarland, Saarbruecken, Saarland, Germany; 2. Institute of Experimental Physics, Saarland University, Saarbrücken, Saarland, Germany*

3:15

FH-04. Oxide electrode on LAO (110) substrate for studying low-symmetry perovskite oxides. *J. Kim*¹, J. Kim¹, H. Na¹, B. Lee¹, I. Choi¹, C. Jung¹ and S. Chae² *1. Dept. of Physics, Hankuk University of Foreign Studies, Yongin, Kyunggi-do, South Korea; 2. School of Physics and Astronomy, Seoul National University, Seoul, South Korea*

3:30

FH-05. Mössbauer studies of the Co_{1-x}Zn_xFe₂O₄ Ferrite. *Y. Zhang*¹, X. Yuan¹, Z. Ren¹, Z. Kou¹, X. Bai², Y. Zhai^{1,2}, Y. Xu³, J. Du² and H. Zhai² *1. Department of Physics, Southeast University, Nanjing, Jiangsu, China; 2. National Laboratory of Solid Microstructures, Nanjing University, Nanjing, Jiangsu, China; 3. Department of Electronics, University of York, York, United Kingdom*

3:45

FH-06. Synthesis of iron oxide nanoparticles of controlled size, shape and magnetic properties. *P. Guardia*¹, A. Labarta¹ and X. Batlle¹ *1. Fundamental Physics, UB, Barcelona, Catalunya, Spain*

4:00

FH-07. The dispersion of BaFe₁₂O₁₉ particles in a liquid. *D. Lisjak*¹ and M. Drofenik^{1,2} *1. Jozef Stefan Institute, Ljubljana, Slovenia; 2. Faculty of Chemistry and Chemical Engineering, University of Maribor, Maribor, Slovenia*

4:15

FH-08. FREEZE Granulation: A novel technique for low-loss MnZn ferrites. *V. Tsakaloudi*¹, G. Kogias¹ and V.T. Zaspalis¹ *1. Laboratory of Inorganic Materials, Centre for Research and Technology Hellas, Thessaloniki, Greece*

WEDNESDAY
AFTERNOON
4:40

AUDITORIO A

11:30

Session WA
INTERMAG PLENARY SESSION
Josef Fidler, Chair

GA-05. Self-Assembly Pattern Multiplication for 1Tb/in² Patterned Media Templates. (Invited)
R. Ruiz¹, E. Dobisz¹, D.S. Kercher¹, T. Wu¹, T.R. Albrecht¹, H. Kang² and P.F. Nealey² *1. San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA; 2. Department of Chemical and Biological Engineering, University of Wisconsin, Madison, WI*

12:00

THURSDAY
MORNING
9:30

AUDITORIO A

GA-06. Fabrication and Characterization of High-density Patterned Media. (Invited) *N. Yasui^{1,2}, S. Ichihara¹, T. Nakamura¹, A. Imada¹, T. Saito¹, R. Horie¹, Y. Ohashi¹, T. Den¹, K. Miura² and H. Muraoka²* *1. Canon Research Center, Tokyo, Japan; 2. RIEC, Tohoku Univ., Sendai, Japan*

Session GA
SYMPOSIUM ON BIT PATTERNED MEDIA
Manfred Schabes, Chair

9:30

GA-01. Achieving tight physical and magnetic sigmas in bit patterned media recording disks. (Invited)
D. Weller¹, A.Y. Dobin¹, D. Kuo¹, K.Y. Lee¹, J. Hwu¹, X. Yang³, S. Xiao³, G. Gauzner¹, M. Feldbaum¹, M. Ostrowski², G. Ju³, H.J. Richter¹, B. Lu¹, B. Valcu¹, X. Zhu³ and R. van de Veerdonk³ *1. Media R&D, Seagate Technology, Fremont, CA; 2. Recording Heads Operations, Seagate Technology LLC, Normandale, MN; 3. Research, Seagate Technology LLC, Pittsburgh, PA*

10:00

GA-02. Modeling and Simulation of the Writing Process on Bit-Patterned Perpendicular Media. (Invited) *H. Muraoka¹, S.J. Greaves¹ and Y. Kanai²* *1. RIEC, Tohoku University, Sendai, Japan; 2. Niigata Institute of Technology, Kashiwazaki, Japan*

10:30

GA-03. Nanoscale perpendicular magnetic island arrays fabricated by extreme ultraviolet interference lithography. (Invited) *F. Luo¹, L.J. Heyderman¹ and H.H. Solak¹* *1. Laboratory for Micro- and Nanotechnology, Paul Scherrer Institut, Villigen, Switzerland*

11:00

GA-04. Magnetic films on self-assembled nanoparticles: An approach for bit-patterned media. (Invited) *M. Albrecht¹, C. Brombacher¹, H. Rohrmann², P. Kappenberger⁴, O. Hellwig³, A. Goncharov⁵ and T. Schrefl⁵* *1. Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany; 2. Data Storage, OC Oerlikon Balzers AG, Balzers, Liechtenstein; 3. San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA; 4. Nanoscale Materials Science, Empa, Duebendorf, Switzerland; 5. Department of Engineering Materials, University of Sheffield, Sheffield, United Kingdom*

MADRID

THURSDAY
MORNING
9:30

Session GB
MR BASED HEADS (GMR, MTJ, CPP)
Brendan Lafferty, Chair

9:30

GB-01. An investigation of noise increased in TMR readers during drive operation. *P. Wong¹* *1. SAE Magnetics (HK) Ltd, Hong Kong, China*

9:45

GB-02. Improvement of TMR effect of magnetic tunneling junctions with very thin MgO barrier sputtered by noble gas mixture at low RA product below 1.0 $\Omega\mu\text{m}^2$ *K. Noma¹, K. Komagaki², K. Sunaga², H. Kanai², Y. Uehara² and T. Umehara¹* *1. Head Manufacturing, Fujitsu Ltd., Nagano, Japan; 2. Advanced Head Technology, Fujitsu Ltd., Nagano, Japan*

10:00

GB-03. Atomic layer deposition Al₂O₃ films for permanent magnet isolation in TMR read heads. *M. Kautzky¹, A. Demtchouk¹, Y. Chen¹, S. McKinlay¹, K. Brown¹ and J. Xue¹* *1. Advanced Transducer Development, Seagate Technology, Bloomington, MN*

10:15

GB-04. Analysis of the current-confined-paths in the film plane for CPP-GMR films. *H. Fukuzawa¹, M. Hara¹, H. Yuasa¹ and Y. Fuji¹* *1. Corporate R&D Center, Toshiba Corporation, Kawasaki, Japan*

10:30

GB-05. Development of CPP-GMR Heads for High-Density Magnetic Recording. (Invited)

J.R. Childress¹, M.J. Carey¹, S. Maat¹, N. Smith¹, X. Liu¹, H. Balamane¹, S. Chandrashekariaih¹, T.D. Boone¹, R.E. Fontana¹, P. Vanderheijden¹, Y. Hong¹, K. Carey¹, J. Tabib¹, J. Li¹, B. York¹, T. Lin¹, J.A. Katine¹, W. Jayasekara¹, N. Robertson¹, M. Alex¹, J. Moore¹ and C. Tsang¹. Hitachi Global Storage Technologies, San Jose, CA

11:00

GB-06. Current Confined Path (CCP) Giant Magneto Resistive (GMR) Sensors. X. Peng¹, P. Kolbo¹, K. Nikolaev¹, S. Chen¹, Z. Wang¹, T. Boonstra¹, P. Anderson¹, S. Kalderon¹, P. Czoschke¹, A. Morrone¹, D. Dimtrov¹, S. Xue¹ and Y. Chen¹. RHO, Seagate Technology, Bloomington, MN

11:15

GB-07. Current Density Limitation by Spin Transfer Torque for CPP-GMR Heads. K. Yamada¹, M. Takagishi¹, M. Takashita¹ and H. Iwasaki¹. Corporate R&D Center, Toshiba Corporation, Kawasaki, Japan

11:30

GB-08. Suppression of spin-torque in current perpendicular to the plane spin-valves by addition of Dy caps. S. Maat¹, M.J. Carey¹, N. Smith¹ and J.R. Childress¹. Hitachi Global Storage Technologies, San Jose, CA

11:45

GB-09. Transport and magnetic properties of CPP-GMR sensor with CoMnSi Heusler alloy. T. Mizuno¹, Y. Tsuchiya¹, T. Machita¹, S. Hara¹, D. Miyauchi¹, K. Shimazawa¹, K. Noguchi¹ and K. Tagami¹. SQ Research Center, TDK CORPORATION, 543 Otai, Saku-shi, Nagano, Japan

12:00

GB-10. Mesoscopic Extraordinary Magnetoresistance and the Effects of Impact Ionization and Velocity Saturation. (Invited) T.D. Boone¹, L. Folks¹, J.A. Katine¹, E.E. Marinero¹, N. Smith¹ and B.A. Gurney¹. San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA

THURSDAY
MORNING
9:30

ROMA

**Session GC
ULTRAFAST DYNAMICS**
Juergen Fassbender, Chair

9:30

GC-01. Ultrafast Magnetic Switching with Terahertz Fields. (Invited) H. Siegmann¹, S.J. Gamble^{2,6}, M.H. Burkhardt^{2,6}, A. Kashuba³, R. Allenspach⁴, S.S. Parkin⁵ and J. Stöhr⁶. 1. PULSE Center Stanford University, Stanford, CA; 2. Dept. of Applied Physics, Stanford University, Stanford, CA; 3. Bogolyubov Institute for Theoretical Physics, Kiev, Ukraine; 4. IBM Research, Zurich Research Laboratory, 8803 Rueschlikon, Switzerland; 5. IBM Almaden Research, San Jose, CA; 6. Stanford Synchrotron Radiation Laboratory, Stanford, CA

10:00

GC-02. Terahertz Emission Spectroscopy as a Probe of Laser-Induced Ultrafast Demagnetization Dynamics. (Invited) E. Beaurepaire¹, J. Arabski¹, M. Vomer¹, J. Bigot¹, S.M. Harrel², J.M. Schleicher² and C.A. Schmuttenmaer². 1. IPCMS-GEMME, CNRS, Strasbourg, France; 2. Dept. of Chemistry, Yale University, New Haven, CT

10:30

GC-03. Atomistic and Multiscale calculations of picosecond magnetisation dynamics. (Invited) R.W. Chantrell¹, U. Nowak¹, O. Chubykalo-Fesenko² and A. Rebei³. 1. Physics, The University of York, York, United Kingdom; 2. ICMM, Madrid, Spain; 3. Seagate Research, Pittsburgh, PA

11:00

GC-04. Femtosecond transfer of angular momentum in ferromagnets probed by X-ray spectroscopy. (Invited) H.A. Dürr¹. 1. BESSY, Berlin, Germany

11:30

GC-05. Laser-induced reorientation of spins in Co/SmFeO₃ heterostructures. J. Loïc¹, F. Nolting¹, A. Kirilyuk², R. Pisarev³, T. Rasing² and A. Kimel². 1. SLS, Paul Scherrer Institut, Villigen-PSI, Switzerland; 2. IMM, Radboud University Nijmegen, Radboud, Netherlands; 3. Ioffe Physical Technical Institute, St. Petersburg, Russian Federation

11:45

GC-06. Heusler alloys: The role of band structure on the ultrafast demagnetization. T. Roth¹, D. Steil¹, A. Conca², M. Jourdan², M. Aeschlimann¹ and M. Cinchetti¹. 1. Physics, TU Kaiserslautern, Kaiserslautern, Germany; 2. Institute of Physics, University of Mainz, Mainz, Germany

12:00

GC-07. Dynamics of the coercivity in (ultrafast) pump-probe experiments. *D. Steil¹, T. Roth¹, M. Cinchetti¹ and M. Aeschlimann¹*. *1. FB Physik, AG Aeschlimann, TU Kaiserslautern, Kaiserslautern, Germany*

12:15

GC-08. LLB-Micromagnetic modelling of ultra-fast optical magnetisation dynamics. *U. Atxitia¹, O. Chubykalo-Fesenko¹, N. Kazantseva², D. Hinzke², U. Nowak² and R.W. Chantrell²*. *1. POMT, ICMM-CSIC, Madrid, Spain; 2. Department of Physics, University of York, York, United Kingdom*

THURSDAY
MORNING
9:30

PARIS

**Session GD
MRAM**
Freitas Paulo, Chair

9:30

GD-01. Switching Characteristics and Bias Voltage Dependence of Spin Torque Switching in MgO based Magnetic Tunnel Junctions. *S. Oh¹, K.T. Nam¹, J.E. Lee¹, W.J. Kim¹, J.H. Jeoung¹, D.K. Kim¹, S.Y. Lee¹, K. Kim², U. Chung¹ and J.T. Moon¹*. *1. Memory Division, Semiconductor Business, Samsung Electronics Co., LTD., Yongin-City, Gyeonggi-Do, South Korea; 2. Semiconductor Device Lab, Samsung Advanced Institute of Technology, Yongin-City, Gyeonggi-Do, South Korea*

9:45

GD-02. Impact of antiferromagnet-induced magnetization fluctuation control on switching current distribution reduction in MRAM. *Y. Katoh¹, H. Hada¹ and N. Kasai¹*. *1. Device Platforms Research Laboratories, NEC Corporation, Kanagawa, Japan*

10:00

GD-03. Spin Torque Random Access Memory down to 22nm Technology. *X. Wang¹, Y. Chen¹, H. Li¹, D. Dimitrov¹ and H. Liu¹*. *1. Seagate Technology, Bloomington, MN, MN*

10:15

GD-04. Multilevel Magnetic Random Access Memory Based on Spin Transfer Torque Switching. *Y. Zhang¹, X. Yao¹ and J. Wang¹*. *1. MINT Center & Electrical and Computer Engineering Department, University of Minnesota, Minneapolis, MN*

10:30

GD-05. Heat-assisted magnetization reversal using pulsed laser irradiation in patterned magnetic thin film with perpendicular anisotropy. *K. Waseda¹, R. Doi¹, B. Purnama¹, S. Yoshimura¹, Y. Nozaki¹ and K. Matsuyama¹*. *1. Dept. of Electronics, Kyushu University, Fukuoka, Japan*

10:45

GD-06. Estimation of Thermal Stability Factor in Current-Induced Magnetization Switching. *H. Suh¹ and K. Lee¹*. *1. Korea University, Seoul, South Korea*

11:00

GD-07. Nano-ring MTJ and nano-ring MRAM. *X. Han¹, Z. Wen¹ and H. Wei¹*. *1. State Key Lab of Magnetism, Institute of Physics, CAS, Beijing, China*

11:15

GD-08. Magnetic characterization of embedded MgO ferromagnetic contacts for spin injection in silicon. *T. Uhrmann¹, T. Dimopoulos¹, D. Schwarz¹, V. Lazarov², D. Kirk², A. Kohn², S. Weyers³, U. Paschen³ and H. Brückl¹*. *1. Nano-Systemtechnologies, Austrian Research Centers GmbH - ARC, Vienna, Austria; 2. Department of Materials, University of Oxford, Oxford, United Kingdom; 3. Fraunhofer Institute of Microelectronic Circuits and Systems, Duisburg, Germany*

11:30

GD-09. High thermal stability and low switching current in a perpendicular-CPP-GMR with an ultrathin epitaxial FePt free layer. *K. Yakushiji¹, S. Yuasa¹, A. Fukushima¹, H. Kubota¹, T. Nagahama¹, T. Katayama¹ and K. Ando¹*. *1. National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan*

11:45

GD-10. Stress assisted reversal of perpendicular magnetization of thin films with giant magnetostriction constant. *N. Saito¹ and S. Nakagawa¹*. *1. Dept. of Physical Electronics, Tokyo Institute of Technology, Tokyo, Japan*

12:00

GD-11. A Novel Macro-Model for Spin-Transfer-Torque based Magnetic-Tunnel-Junction Elements. *S. Lee¹, H. Lee¹, S. Lee¹ and H. Shin¹* *1. Information Electronics Engineering, Ewha W. Univ., Seoul, South Korea*

12:15

GD-12. Random number generation by current induced magnetization switching in a MgO magnetic tunnel junction. *A. Fukushima¹, K. Yakushiji¹, H. Kubota¹, S. Yuasa¹ and K. Ando¹* *1. NeRI, AIST, Tsukuba, Ibaraki, Japan*

THURSDAY
MORNING
9:30

LONDRES

Session GE MAGNETIC NANOPARTICLES II

Dino Fiorani, Chair

9:30

GE-01. Towards dense regular arrays of FePt nanomagnets by gas phase deposition onto bacterial S-layers within a horizontal magnetic field. *U. Queitsch¹, D. Pohl¹, A. Blüher², M. Mertig², L. Schultz¹ and B. Rellinghaus¹* *1. Metastable and Nanostructured Materials, Leibniz Institute for Solid State and Materials Research Dresden, Dresden, Saxony, Germany; 2. Max Bergmann Center of Biomaterials, Dresden University of Technology, Dresden, Saxony, Germany*

9:45

GE-02. Magnetic anisotropy of a single Fe atom on Pt(111). *T. Schuh¹, T. Balashov¹, A.F. Takacs¹, W. Wulfhekel¹, A. Ernst², S. Ostanin², J. Henk², P. Bruno², T. Miyamachi³ and S. Suga³* *1. Physikalisches Institut, Universität Karlsruhe, Karlsruhe, Germany; 2. Max-Planck Institut für Mikrostrukturphysik, Halle, Germany; 3. Graduate School of Engineering Science, Osaka University, Osaka, Japan*

10:00

GE-03. High-moment synthetic magnetic nanoparticles for biomedical applications. *W. Hu¹, R.J. Wilson¹, C.M. Earhart¹, A. Koh^{1,2}, A.Z. Faranesh³, R. Sinclair¹, S. Guccione³ and S.X. Wang^{1,4}* *1. Materials Science & Engineering, Stanford University, Stanford, CA; 2. Mechanical Engineering, Stanford University, Stanford, CA; 3. Radiology, Stanford University, Stanford, CA; 4. Electrical Engineering, Stanford University, Stanford, CA*

10:15

GE-04. Highly anisotropic FePt nanomagnets obtained via Fe ion implantation on Pt films. *R.A. Lukaszew^{1,2}, C. Clavero¹ and J.R. Skuza²* *1. Applied Science Dept., College of William and Mary, Williamsburg, VA; 2. Physics Department, College of William and Mary, Williamsburg, VA*

10:30

GE-05. Surface relaxation and magnetism in monodisperse binary metal nanoparticles. (Invited) *M. Farle¹* *1. Physik, Universitaet Duisburg-Essen, Duisburg, Germany*

11:00

GE-06. Synthesis and characterisation of polymer-coated Fe nanoparticles with high magnetisation. *J. Marin², A. Garcia Prieto¹, I. Orue³, J. Vilas², M. Fdez-Gubieda¹ and L.M. Leon²* *1. Dpto Electricidad y Electronica, Universidad del Pais Vasco - UPV/EHU, Bilbao, Spain; 2. Dpto Química Macromolecular, Universidad del Pais Vasco - UPV/EHU, Bilbao, Spain; 3. SGIKER Medidas Magnéticas, Vicerrectorado de Investigación, Universidad del Pais Vasco - UPV/EHU, Bilbao, Spain*

11:15

GE-07. Bulk-like magnetic properties in Fe₃O₄ nanoparticles: surface anisotropy, orbital moment and crystal quality. *N. Pérez^{1,2}, P. Guardia^{1,2}, A.G. Roca³, M.P. Morales³, C.J. Serna³, F. Bartolomé^{4,5}, L.M. García^{4,5}, J. Bartolomé^{4,5}, J.C. Cezar⁶, A. Labarta^{1,2} and X. Batlle^{1,2}* *1. Física Fonamental, Universitat de Barcelona, Barcelona, Catalonia, Spain; 2. Institut de Nanociencia i Nanotecnologia IN2UB, Universitat de Barcelona, Barcelona, Catalonia, Spain; 3. ICMM, CSIC, Madrid, Madrid, Spain; 4. ICMA, CSIC, Zaragoza, Aragón, Spain; 5. Física de la Materia Condensada, Universidad de Zaragoza, Zaragoza, Aragón, Spain; 6. ESRF, Grenoble, France*

11:30

GE-08. On the spin reorientation of magnetic nano-dot arrays: Co/Au versus Co/Pt on SiGe. *A. Persson¹, L. Gridneva¹, M.A. Niño², J. Camarero², J.J. de Miguel², R. Miranda², C. Hofer³, C. Teichert³, T. Bobek⁴ and D. Arvanitis¹* *1. Physics Department, Uppsala University, Uppsala, Sweden; 2. Departamento de Física de la Materia Condensada, Universidad Autonoma de Madrid, Madrid, Spain; 3. Institut für Physik, Montanuniversität Leoben, Leoben, Austria; 4. Institute of Semiconductor Electronics, Aachen University, Aachen, Germany*

11:45

GE-09. Perpendicular anisotropy in Co/Pt granular multilayers. *J. Bartolomé¹, L. García Vinuesa¹, F. Bartolomé¹, J. Stankiewicz¹, F. Luis¹, F. Petroff², C. Deranlot², F. Wilhelm³, A. Rogalev³, P. Bencok³ and N.B. Brookes³* *1. Instituto de Ciencia de Materiales de Aragón, CSIC/U. de Zaragoza, Zaragoza, Spain; 2. Unité Mixte de Physique, CNRS/Thales, Orsay (Paris), France; 3. ESRF, Grenoble, France*

12:00

GE-10. Evidence of L10 chemical order in CoPt nanoclusters: direct observation and magnetic signature. *F. Tournus*¹, A. Tamion¹, N. Blanc¹, A. Hannour¹, L. Bardotti¹, B. Prével¹, P. Ohresser², E. Bonet³, T. Epicier⁴ and V. Dupuis¹. *1. LPMC/N, Université de Lyon; Univ. Lyon 1; CNRS, Villeurbanne, France; 2. Synchrotron SOLEIL, Gif sur Yvette, France; 3. Institut Néel, CNRS/UJF, Grenoble, France; 4. MATEIS, CNRS; INSA Lyon; Université de Lyon, Villeurbanne, France*

12:15

GE-11. Magnetic Hardening of FePt Nanomagnets by Ultra Short Time In-Flight Annealing. E. Mohn¹, B. Rellinghaus¹ and L. Schultz¹. *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany*

THURSDAY
MORNING
9:30

BERLIN

Session GF
HEAD-MEDIA INTERFACE AND TRIBOLOGY II
Singh Bhatia, Chair

9:30

GF-01. Flying Characteristics on Discrete Track and Patterned Media With Thermal Protrusion Slider. (Invited) *B.E. Knigge*¹, *Z.Z. Bandic*¹ and *D. Kercher*¹. *San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA*

10:00

GF-02. Nonuniform distribution of molecularly thin lubricant caused by inhomogeneous buried layers of discrete track media. *K. Fukuzawa*^{1,2}, *T. Muramatsu*¹, *H. Amakawa*¹, *S. Itoh*¹ and *H. Zhang*¹. *1. Micro/Nano Systems Engineering, Nagoya University, Nagoya, Japan; 2. PRESTO, JST, Kawaguchi, Japan*

10:15

GF-03. Parametric Study of Contact Performance for Discrete Track Recording Media Using Finite Element Analysis. *C. Yeo*¹ and *A.A. Polycarpou*¹. *1. Mechanical Science and Engineering, Univ. of Illinois at Urbana-Champaign, Urbana, IL*

10:30

GF-04. Numerical and Experimental Investigation of “Flyability” of Sliders on Discrete Track Recording Media. *Y. Yoon*¹, *M. Duwensee*², *J. Lin*³, *S. Suzuki*³ and *F.E. Talke*¹. *1. Mechanical Engineering, University of California, San Diego, La Jolla, CA; 2. Hitachi Global Storage Technologies, San Jose, CA; 3. Western Digital Corporation, San Jose, CA*

10:45

GF-05. Dynamic analysis schemes for flying head sliders over discrete track media. *S. Fukui*¹, *T. Kanamaru*¹ and *H. Matsuo*¹. *1. Dept. of Applied Mathematics and Physics, Tottori University, Tottori City, Japan*

11:00

GF-06. Effect of van der Waals Force on Ultimate Head-to-Disk Interface. *K. Ono*¹. *1. Storage Technology Research Center, Hitachi Central Research Laboratory, Fujisawa-shi, Japan*

11:15

GF-07. STUDY ON CONTACT OF THERMAL ACTUATED SLIDER AND DISK. *M. Zhang*¹, *B. Liu*^{1,2} and *S. Hu*¹. *1. Spintronics, Media and Interface Division, Data Storage Institute, Singapore, Singapore; 2. Nanyang Technological University, Singapore, Singapore*

11:30

GF-08. Numerical and Experimental Analyses of Nanometer-scale Flying Height Control of Magnetic Head with Heating Element. *J. Juang*¹, *T. Nakamura*³, *B. Knigge*¹, *Y. Luo*², *W. Hsiao*², *K. Kuroki*³, *F. Huang*¹ and *P. Baumgart*¹. *1. San Jose Research Center, Hitachi GST, San Jose, CA; 2. Hitachi GST, San Jose, CA; 3. Hitachi GST, Fujisawa-shi, Kanagawa-ken, Japan*

11:45

GF-09. Dynamics of Fly-Contact Head-Disk Interface. *S. Yu*¹, *B. Liu*¹, *W. Hua*¹, *W. Zhou*¹ and *C. Wong*¹. *1. Data Storage Institute, Singapore, Singapore*

12:00

GF-10. Slider Optical Constant Distribution, n and k Correlation, and FH Measurement Accuracy. *Z. Yuan*¹, *C. Ong*¹, *B. Liu*¹, *J. Liu*² and *S. Yoshida*². *1. DSI, Singapore, Singapore; 2. Hitachi Asia, SG, Singapore*

12:15

GF-11. A Method for Identification of Pitch and Roll Stiffness of Head-Gimbal Assembly at Flying State. *Q. Zeng¹, Y. Fu¹, C. Yang¹, B. Aujla¹ and E. Cha¹. SAE Magnetics, Milpitas, CA*

THURSDAY
MORNING
9:30

AMSTERDAM

Session GG
HYSTERESIS MODELLING II
Alexandru Stancu, Chair

9:30

GG-01. 2D finite element simulations for bulk steel hysteresis curve derivations. *P. Meilland¹, S. He², S. Depeyre², M. Bernadou² and J. Cagnol². ArcelorMittal Maizières Research, Maizières-lès-Metz, France; 2. Pôle Universitaire Léonard de Vinci, Paris-La Défense, France*

9:45

GG-02. Rotational saturation properties of isotropic vector hysteresis models using vectorized stop and play hysterons. *T. Matsuo¹. Electrical Engineering, Kyoto University, Kyoto, Japan*

10:00

GG-03. Viscous behavior of ferromagnets in the voltage and current driven regimes. *S.E. Zirka¹, Y.I. Moroz¹, P. Marketos², A.J. Moses² and D.C. Jiles². Department of Applied Physics and Technology, Dnepropetrovsk National University, Dnepropetrovsk, Ukraine; 2. School of Engineering, Cardiff University, Cardiff, Wales, UK, United Kingdom*

10:15

GG-04. Size effects influence on hysteresis and relaxation for a Random Anizotropy Ising System. *C. Enachescu¹ and A. Stancu¹. Department of Physics, Alexandru Ioan Cuza University, Iasi, Romania*

10:30

GG-05. Correction of permeability of a soft ferromagnet measured by using vibrating sample magnetometer. *M. Chan¹, C. Ong¹ and Y. Wong¹. Department of Applied Physics and Materials Research Center, The Hong Kong Polytechnic University, Hong Kong, China*

10:45

GG-06. The temperature dependence of magnetostatic interactions in nanowires systems. *A. Diaconu¹, I. Dumitru¹ and A. Stancu¹. Department of Solid State and Theoretical Physics, “Alexandru Ioan Cuza” University, Iasi, Iasi, Romania*

11:00

GG-07. A magnetostriction model with stress dependence for real-time control applications. *D. Davino¹, A. Giustiniani² and C. Visone¹. Engineering Department, University of Sannio, Benevento, Italy; 2. DIIIIE, University of Salerno, Salerno, Italy*

11:15

GG-08. An Improved Engineering Model of Vector Magnetic Properties of Grain-oriented Electrical Steels. *Y. Zhang¹, Y. Eum², C. Koh² and D. Xie¹. School of Electrical Engineering, Shenyang University of Technology, Shenyang, Liaoning 110023, China; 2. School of Electrical & Computer Engineering, Chungbuk National University, Cheongju, Chungbuk 361- 763, South Korea*

11:30

GG-09. Magnetic behaviour of assemblies of nanoparticles with core/shell morphology: Interparticle interaction effects. *M. Vasilakaki¹, K.N. Trohidou¹ and J.A. Blackman². Institute of Materials Science, NCSR “Demokritos”, Athens, Greece; 2. Department of Physics, Reading University, Reading, United Kingdom*

11:45

GG-10. Compensation of Hysteresis and Time- dependent Error for Magnetostrictive Actuators. *H. Choi¹ and Y. Park¹. Mechatronics Engineering, Chungnam National University, Daejeon, South Korea*

12:00

GG-11. Rotational hysteresis first-order reversal curves diagrams as test problem for vectorial hysteresis models. *L. Stoleriu¹, P. Postolache¹, P. Andrei² and A. Stancu¹. Department of Physics, Alexandru Ioan Cuza University, Iasi, Romania; 2. Department of Electrical and Computer Engineering, Florida State University and Florida A&M University, Tallahassee, FL*

12:15

GG-12. Identification of the parameters of reduced vector Preisach model by neural networks. *M. Trapanese¹. Dipartimento di Ingegneria Elettrica, Elettronica e delle Telecomunicazioni, University of Palermo, Palermo, Italy*

THURSDAY
MORNING
9:30

CARACAS

11:00

Session GH

PERMANENT MAGNET MATERIALS - APPLICATIONS III

Jesus Gonzalez, Chair

9:30

GH-01. Analysis of Permanent Magnet Demagnetization Accounting for Minor BH-curves.

Y. Zhilichev¹ 1. Magnequench International, Inc, Durham, NC

9:45

GH-02. A Hybrid Dual-Memory Motor. *C. K.t.¹, G. Yu^{1,2} and J. Jianzhong² 1. Electrical and Electronic Engineering, the University of Hong Kong, Hongkong, China; 2. Automation, Shanghai University, Shanghai, China*

10:00

GH-03. Study on Detachment of a Permanent Magnet-Wheel for a Wall-Climbing Mobile Robot using Magnetic Inducement. *H. Yi¹, J. Kim¹ and S. Han² 1. Mechanical Engineering, Yeungnam University, Gyeongsan, Gyeongsangbuk-do, South Korea; 2. Automobile engineering, Yeungnam College of Science & Technology, Daegu, South Korea*

10:15

GH-04. Ironless and leakage free voice-coil motor made of bounded magnets. *G. Lemarquand¹, M. Remy², B. Castagnede¹ and G. Guyader² 1. LAUM, Universite du Maine, Le Mans, France; 2. Renault, Guyancourt, France*

10:30

GH-05. Generic Algorithm-Based Optimal Design of New Electromagnetic Engine Valve Actuator for Reduction of Transition Time. *J. Kim¹, K. Han² and J. Chang³ 1. Mechanical Engineering, Yeungnam University, Gyeongsan, Gyeongsangbuk-do, South Korea; 2. Electrical Engineering, Florida Institute of Technology, Melbourne, FL; 3. Transverse Flux Machines Research Group, Korea Electrotechnology Research Institute, Changwon, Kyungsangnam-Do, South Korea*

10:45

GH-06. Self-Assembly of Millimeter-Scale Components using Integrated Micromagnets. *S.B. Shetye¹ and D.P. Arnold¹ 1. Interdisciplinary Microsystems Group, University of Florida, Gainesville, FL*

GH-07. Minimization of Cogging Torque in an IPM Machine. *C. Hwang¹, P. Li¹ and C. Liu² 1. EE, Feng Chia University, Seatwen, Taichung, Taiwan; 2. EE, National Sun Yat-sen University, Kaohsiung, Taiwan*

11:15

GH-08. Static Eccentricity Fault Diagnosis in Permanent Magnet Synchronous Motor using Time Stepping Finite Element Method. *B. Ebrahimi¹, J. Faiz¹ and A. Zargham Nejhad¹ 1. Department of Electrical and Computer Engineering, University of Tehran, University of Tehran, Tehran, Iran*

11:30

GH-09. Six-degree-of-freedom motion analysis of a planar actuator with a magnetically levitated mover by six-phase current controls. *Y. Ueda¹ and H. Ohsaki¹ 1. Department of Advanced Energy, The University of Tokyo, Kashiwa, Japan*

11:45

GH-10. Optimal Halbach Permanent Magnet Shapes for Slotless Tubular Actuators. *J.J. Paulides¹, K.J. Meessen¹, B.L. Gysen¹ and E.A. Lomonova¹ 1. Technical university Eindhoven, Eindhoven, Netherlands*

12:00

GH-11. Development of Inverse Magnetostrictive Actuator. *H. Park¹, Y. Park¹ and H. Choi¹ 1. Mechatronics Engineering, Chungnam National University, Daejeon, South Korea*

GH-12. WITHDRAWN

THURSDAY
MORNING
9:00

POLIVALENTE

Session GL

MULTILAYER FILMS AND SUPERLATTICES II
(POSTER SESSION)

Alex Dobin, Chair

GL-01. Interface effects in the magnetic properties of $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{SrTiO}_3$ heterostructures. *(Invited) F.Y. Bruno¹, J. Garcia-Barriocanal¹, A. Rivera¹, Z. Sefrioui¹, C. Leon¹, J. Santamaria¹, N.M. Nemes², M. Garcia-Hernandez², M. Varela³ and S.J. Pennycook³ 1. GFMC. Dpto. Fisica Aplicada III., Universidad Complutense de Madrid, Madrid, Madrid, Spain; 2. Instituto de Ciencia de Materiales de Madrid, Consejo Superior de Investigaciones Cientificas, Cantoblanco, Madrid, Spain; 3. Condensed Matter Science Division, Oak Ridge National Laboratory, Oak Ridge, TN*

GL-02. Control of the degree of out-of-plane anisotropy of CoFe/Tb multilayer by applying an external in-plane field during film deposition. *K. Lee¹, Y. Jang¹, J. Kim¹, S. Lee¹ and B. Cho¹*. *School of Photonics, MSE, GIST, Gwangju, South Korea*

GL-03. Effect of the Cr insertion layer on synthetic antiferromagnetic coupling in magnetic tunnel junctions. *K. Kim¹, W. Kim², S. Oh², D. Kim², I. Hwang¹, K. Kim¹, S. Seo¹, J. Jeong², K. Nam² and J. Lee²*. *1. Semiconductor Devices Lab, Samsung Advanced Institute of Technology (SAIT), Yongin-Si, Gyeonggi-Do, South Korea; 2. Process Development Team, Samsung Electronics Co., Ltd, Yongin-Si, Gyeonggi-Do, South Korea*

GL-04. Preparation and magnetic characterization of Fe/MgO layered granular thin films. *A. García-García¹, J.A. Pardo^{2,3}, P.A. Algarabel¹, C. Magén⁴, P. Strichovanec², L. Morellón^{1,2}, J.M. De Teresa¹, A. Vovk² and M.R. Ibarra^{1,2}*. *1. Instituto de Ciencia de Materiales de Aragón, Universidad de Zaragoza-CSIC, Zaragoza, Spain; 2. Instituto de Nanociencia de Aragón, Universidad de Zaragoza, Zaragoza, Spain; 3. Departamento de Ciencia y Tecnología de Materiales y Fluidos, Universidad de Zaragoza, Zaragoza, Spain; 4. Centre d'Elaboration de Matériaux et d'Etudes Structurales, CNRS, Toulouse, France*

GL-05. FMR Investigation of (Ga_{1-x}Mn_x)As Tri-layers. *M. Cubukcu¹, K. Khazen¹, H. von Bardeleben¹, J. Cantin¹, M. Elsen², H. Jaffrès², J. George², L. Thevenard³ and A. Lemaître³*. *1. Institut des Nanosciences de Paris (INSP), Université Paris 6, UMR 75-88 au CNRS, Paris, Ile de France, France; 2. Unité Mixte de Physique CNRS-Thales, associée à l'Université Paris XI, Palaiseau, Ile de France, France; 3. Laboratoire de Photonique et Nanostructures, Marcoussis, Ile de France, France*

GL-06. Interplay between magnetic anisotropy and interlayer exchange coupling in amorphous CoSi / Si multilayers. *L.M. Álvarez-Prado¹, C. Quirós¹, L. Zárate¹, J.I. Martín¹ and J.M. Alameda¹*. *Departamento de Física, Universidad de Oviedo, Oviedo, Asturias, Spain*

GL-07. Creation of out-of-plane magnetization ordering by increasing multilayer number N in [Co/Au]_N multilayers. *M. Tekielak^{1,2}, P. Mazalski¹, A. Maziewski^{1,3}, R. Schäfer², J. McCord², B. Szymanski⁴, M. Urbaniak⁴ and F. Stobiecki⁴*. *1. Department of Physics, University of Białystok, Białystok, Poland; 2. Leibniz-Institut für Festkörper- und Werkstoffforschung Dresden e.V, Dresden, Germany; 3. Laboratoire de Physique des Solides, Université Paris-Sud, Orsay, France; 4. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland*

GL-08. Magnetostatic waves in the magnetic/nonmagnetic periodic structures. *M. Krawczyk¹*. *Faculty of Physics, Adam Mickiewicz University, Poznan, Poland*

GL-09. Investigations on magnetic properties of NiFe film doped with Gd by ferromagnetic resonance. *Y. Fu¹, L. Sun^{1,3}, J. Wang¹, Z. Kou¹, Y. Zhai^{1,2}, X. Bai², J. Wu³, Y. Xu⁴, J. Du², H. Lu² and H. Zhai²*. *1. Department of Physics, Southeast University, Nanjing, Jiangsu, China; 2. National Laboratory of Solid Microstructures, Nanjing University, Nanjing, Jiangsu, China; 3. Department of Physics, University of York, York, United Kingdom; 4. Department of Electronics, University of York, York, United Kingdom*

GL-10. Hard Magnetic Nanocomposite [NdFeBNbCu/FeBSi]_{xn} Multilayer Films with Low Crystallization Temperature. *H. Chiriac¹, M. Grigoras¹, N. Lupu¹ and M. Urse¹*. *National Institute of Research & Development for Technical Physics, Iasi, Romania*

GL-11. Magneto-optical circular dichroism properties of fept layers with perpendicular anisotropy. *C. de Julian Fernandez¹, R. Novak², F. Albertini³, F. Casoli³, S. Fabbri³ and A. Caneschi¹*. *1. Chemistry, INSTM- University of Florence, Sesto Fiorentino (FI), Italy; 2. Physics, INSTM- University of Florence, Sesto Fiorentino (FI), Italy; 3. Magnetic Materials, IMEM - CNR, Parma, Italy*

GL-12. Structural and Magnetic Properties of Fe/Polyimide Multilayer Thin Film. *J. Kim¹, S. Kim¹, N. Oh¹, H. An¹, J. Kim¹, D. Jeong¹, C. Kim¹ and C. Yoon¹*. *Materials Science and Engineering, Hanyang University, Seoul, South Korea*

GL-13. The magnetic anisotropies of FeCo and FeCoGd films. *L. Sun^{1,2}, J. Wang¹, Y. Fu¹, Z. Kou¹, Y. Zhai^{1,4}, X. Bai⁴, J. Wu³, Y. Xu², J. Du⁴, H. Lu⁴ and H. Zhai⁴*. *1. Department of Physics, Southeast University, Nanjing, Jiangsu, China; 2. Department of Physics, University of York, York, United Kingdom; 3. Department of Electronics, University of York, York, United Kingdom; 4. National Laboratory of Solid Microstructures, Nanjing University, Nanjing, Jiangsu, China*

**THURSDAY
MORNING
9:00**

POLIVALENTE

Session GM
PERMANENT MAGNET MACHINES IV
(POSTER SESSION)
Aly Flores Filho, Chair

GM-01. The energy loss by drag force of superconductor flywheel energy storage system with permanent magnet rotor. *J. Lee¹, Y. Han¹, S. Jung¹, T. Sung¹ and B. Park¹*. *Korea Electric Power Research Institute, Daejeon, South Korea*

GM-02. Analysis of eddy-current loss in a double-stator cup-rotor PM machine. *S. Niu¹, K. Chau¹ and J. Jiang²*. *1. Depart. of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, China; 2. School of Electromechanical Engineering and Automation, Shanghai University, Shanghai, China*

GM-03. Comparison of stator-permanent-magnet brushless machines. *C. Liu¹ and K. Chau¹*. *Dept. of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, China*

GM-04. Segmentation of magnets to reduce losses in permanent magnet synchronous machines. *P. Sergeant¹ and A. Van den Bossche¹*. *1. Department of Electrical Energy, Systems and Automation, Ghent university, Gent, Belgium*

GM-05. Cogging Torque Reduction in Brushless DC Motors Due to the Magnetization Distribution in Permanent Magnets. *T. Ishikawa¹, K. Yonetake¹, M. Matsunami¹ and M. Tsuchiya²*. *1. Electronic Engineering, Gunma University, Kiryu, Japan; 2. Tokyo Parts Industrial Co.,LTD., Isesaki, Japan*

GM-06. Negative Stiffness of Toroidally-Wound BLDC Machine. *M. Noh¹ and H. Lee¹1. Mechatronics Engineering, Chungnam National University, Daejeon, South Korea*

GM-07. A STUDY ON THE DESIGN OF AN INSET PERMANENT MAGNET TYPE FLUX-REVERSAL MACHINE. *T. Kim¹1. Electrical Engineering, Gyeongsang National University, Jinju, South Korea*

GM-08. A Comprehensive Comparison of Flux-Switching and Flux-Reversal Brushless PM Machines. *H. Wei¹, C. Ming¹, Z. Wenxiang¹, Z. Jianzhong¹ and J. Hongyun¹1. School of Electrical Engineering, Southeast University, Nanjing, 210096, China*

GM-09. Optimization and electromagnetic analysis of stator interior permanent magnet machine with minimum cogging torque. *J. Zhang¹, M. Cheng¹ and W. Zhao¹1. school of electrical engineering, Southeast University, Nanjing, Jiangsu, China*

GM-10. Design and analysis of line-starting three- and single-phase interior permanent magnet synchronous motors; direct comparison to induction motor characteristics. *T. Mar čič¹, B. Stumberger^{2,1}, G. Stumberger^{2,1}, M. Hadziselimovi č^{2,1}, P. Vrtič¹ and D. Dolinar^{2,1}1. TECES, Research and Development Centre for Electrical Machines, Maribor, Slovenia; 2. University of Maribor, Faculty of Electrical Engineering and Computer Science, Maribor, Slovenia*

GM-11. Design and analysis of large capacity line-start permanent magnet synchronous motors. *Q. Lu¹ and Y. Ye¹1. college of electrical engineering, Hangzhou, Zhejiang, China*

GM-12. An Application of the Latin Hypercube Sampling Strategy for Optimal Design of Large Scale Permanent magnet pole using Adaptive Response Surface Method. *P. Shin¹, S. Woo¹, Y. Zhang² and C. Koh²1. Electrical Engineeirng, Hongik University, Chungnam, South Korea; 2. Electrical and Computer Engineering, Chungbuk National University, Chungbuk, South Korea*

GN-03. Characteristic Comparison between the Spiral and Lamination Stator in Axial Field Slotless Machines. *S. Lee¹, J. Hong¹, T. Lee² and J. Park²1. Automotive Engineering, Hanyang university, Seoul, South Korea; 2. Mechanical Engineering, Hanyang university, Seoul, South Korea*

GN-04. Investigation and comparison of inductance calculation methods in interior permanent magnet synchronous motors. *T. Sun¹, S. Kwon¹, J. Lee¹ and J. Hong¹1. Department of Mechanical Engineering, Hanyang University, Seoul, South Korea*

GN-05. Two-DOF micro magnetostrictive bending actuator for wobbling motion. *T. Ueno¹, C. Saito², N. Imaizumi² and T. Higuchi¹1. University of Tokyo, Tokyo, Japan; 2. Namiki Precision Jewel Co., LTD, Tokyo, Japan*

GN-06. Thrust calculations and measurements of cylindrical linear oscillatory actuator with halbach array moving magnet using transfer relations theorem. *S. Jang¹, H. Kim¹, J. Choi¹ and S. Lee²1. Chungnam National University, Daejeon, South Korea; 2. Korea Institute of Industrial Technology, Kwangju, South Korea*

GN-07. CHARACTERISTIC ANALYSIS OF A FLUX-REVERSAL MOTOR WITH FOUR-SWITCH CONVERTER. *H. Kang², T. Kim¹ and B. Lee²1. Electrical Engineering, Gyeongsang National University, Jinju, South Korea; 2. Sungkyunkwan University, Suwon, South Korea*

GN-08. Iron Loss Calculation in an Amorphous Transformer Using Coupled Preisach Modeling & Finite Element Method. *Y. Cho¹ and S. Mun¹1. Electrical Engineering, Hanbat National University, Daejeon, South Korea*

GN-09. Reduction of Lateral Force using V-skew in Permanent Magnet Linear Synchronous Motor. *D. Lee¹, K. Jang¹ and G. Kim¹1. Electrical Engineering, Changwon National University, Changwon, Gyeongsangnam-do, South Korea*

GN-10. Axial-gap type permanent magnet motor modeling for transient analysis. *S. Won¹, J. Choi¹ and J. Lee¹1. Electrical Eng., Hanyang University, Seoul, South Korea*

GN-11. Analysis of Total Harmonic Distortion in microspeaker considering electromagnetic mechanical acoustic coupling effect. *J. Kwon¹, S. Hwang¹ and G. Hwang²1. Mechanical Engineering, Pusan National University, Busan, South Korea; 2. Computer Engineering, Youngsan University, Yangsan-city, Kyungnam-do, South Korea*

THURSDAY
MORNING
9:00

POLIVALENTE

Session GN MOTORS AND ACTUATORS III (POSTER SESSION)

Ranran Lin, Chair

GN-01. Development of an axial-flux brushless motor for low-profile fan applications. *L. Hsu¹, C. Huang¹, M. Tsai¹ and G. Yan²1. Electric Motor Technology Research Center, National Cheng Kung University, Tainan, Taiwan; 2. Metal Industries Research & Development Centre, Kaohsiung, Taiwan*

GN-02. Sliding Mode Control for Optical Image Stabilization Actuators. *H. Yu^{1,2}, T. Liu¹ and C. Chiang¹1. Department of Mechanical Engineering, National Chiao Tung University, Hsinchu, Taiwan; 2. Electronics and Opto-electronics Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan*

THURSDAY
MORNING
9:00

POLIVALENTE

Session GO LIFE SCIENCES: TECHNIQUES AND INSTRUMENTATION II (POSTER SESSION)

Jose Rivas, Chair

GO-01. Wide dynamic range digital FLL system using high- T_c SQUID for biomagnetic measurements. *D. Oyama^{1,2}, K. Kobayashi¹, M. Yoshizawa¹ and Y. Uchikawa³1. Graduate School of Engineering, Iwate University, Morioka, Iwate, Japan; 2. Japan Society for the Promotion of Science Research Fellow, Tokyo, Japan; 3. Department of Electronics and Computer Engineering, School of Science and Engineering, Tokyo Denki University, Hatoyama, Saitama, Japan*

GO-02. Double relaxation oscillation SQUID mounted on Pulse Tube cryocooler. *M.J. Eshraghi¹ and I. Sasada¹ 1. Applied science for electronics and materials, Kyushu University, Kasuga, Fukuoka, Japan*

GO-03. Quantitative magnetic immunoassays with a SQUID by means of mutual inductance calculations. *A. Bruno¹, H.R. Carvalho¹, S.R. Louro¹ and C. Paulo¹ 1. Physics, Pontifical Catholic University of Rio de Janeiro, Rio de Janeiro, Brazil*

GO-04. Detection of MCG signal by using MgB₂ SQUID on pulse-tube cooler. *D. Oyama^{1,2}, Y. Harada³, Y. Fujine¹, K. Kobayashi¹, Y. Uchikawa⁴ and M. Yoshizawa¹ 1. Graduate School of Engineering, Iwate University, Morioka, Iwate, Japan; 2. Japan Society for the Promotion of Science Research Fellow, Tokyo, Japan; 3. Japan Science and Technology Agency Innovation Satellite Iwate, Morioka, Iwate, Japan; 4. Department of Electronics and Computer Engineering, School of Science and Engineering, Tokyo Denki University, Hatoyama, Saitama, Japan*

GO-05. Biomagnetic Signal Detection Using Very High Sensitive MI Sensor for Medical Applications. *T. Uchiyama¹, S. Tajima¹, S. Shibata¹, L. Ji¹ and K. Bushida² 1. Electrical Engineering, Nagoya University, Nagoya, Japan; 2. UNITIKA LTD, Tokyo, Japan*

GO-06. Giant magnetoimpedance of electrochemically surface modified Co-based amorphous ribbons. *V. Fal Miyar¹, M. Cerdeira¹, J.A. García¹, A.P. Potatov², R. Pierna³, F.F. Marzo³, J.M. Barandiarán⁴ and G.V. Kuryandskaya⁴ 1. Department of Physics, University of Oviedo, Oviedo, Asturias, Spain; 2. Institute of Metal Physics, Ekaterinburg, Russian Federation; 3. Dpto. de Ingeniería Química y Medio Ambiente, Universidad del País Vasco, San Sebastián, Basque Country, Spain; 4. Department of Electricity and Electronics, Basque Country University, Bilbao, Basque Country, Spain*

GO-07. Spatially arterial pulse diagnostic apparatus using array Hall devices. *S. Lee¹, G. Kim², M. Ahn³, Y. Park³, D. Hwang¹, J. Rhee⁴ and H. Yoon⁵ 1. Oriental Biomedical Engineering, Sangji University, Wonju, Gangwondo, South Korea; 2. Oriental Medicine Science, Sangji University, Wonju, Gangwondo, South Korea; 3. Oriental-western Biomedical Engineering, Sangji University, Wonju, Gangwondo, South Korea; 4. Physics, Sookmyung Women's University, Seoul, Seoul, South Korea; 5. Biomedical Engineering, Yonsei University, Wonju, Gangwondo, South Korea*

GO-08. Various Types of Hall Sensors for Single Particle Detection. *O. Kazakova¹, J. Gallop¹, D. Cox^{1,2}, A. Cuenat¹, L. Brown¹, K. Suzuki³, L. Bernau⁴ and I. Utke⁴ 1. NPL, Teddington, United Kingdom; 2. Surrey University, Guildford, United Kingdom; 3. NTT Basic Research Laboratories, Kanagawa, Japan; 4. EMPA, Thun, Switzerland*

GO-09. Microwaves Doppler transducer for noninvasive monitorisation of the cardiorespiratory activity. *O.I. Baltag² and M.P. Costin^{1,2} 1. Computer Science Institute, Romanian Academy, Iasi, Romania; 2. Faculty of Biomedical Engineering, "Gr.T.Popa" University of Medicine and Pharmacy, IASI, Romania*

GO-10. Investigating the cortical connectivity in the brain by combined TMS and EEG. *K. Iramina^{1,2}, T. Arimatsu¹, H. Sato¹, A. Hyodo², T. Hayami³ and S. Ueno⁴ 1. Department of Intelligent Systems, Kyushu University, Fukuoka, Japan; 2. Graduate School of Systems Life Sciences, Kyushu University, Fukuoka, Japan; 3. Digital Medicine Initiative, Kyushu University, Fukuoka, Japan; 4. Department of Applied Quantum Physics, Kyushu University, Fukuoka, Japan*

GO-11. Fabrication of new magnetic micro-machines for low-invasive surgery. *C. Troisi¹, M. Knaflitz¹, E. Olivetti², L. Martino² and G. Durin² 1. Dep. of Electronics, Politecnico di Torino, Torino, Italy; 2. Istituto Nazionale di Ricerca Metrologica, Torino, Italy*

GO-12. Magnetic Tracking of Eye Motion in Small, Fast-Moving Animals. *A. Plotkin¹, E. Paperno¹, G. Vasserman² and R. Segev² 1. Electrical and Computer Engineering, Ben-Gurion University of the Negev, Beer-Sheva, Israel; 2. Life Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel*

GO-13. Minimization of Computational Errors in Diffusion Simulation of Nuclear Magnetization. *T. Imae^{1,2}, H. Shinohara², M. Sekino³, H. Ohsaki³, S. Ueno⁴, K. Mima¹ and K. Ootomo¹ 1. Department of Radiology, University of Tokyo Hospital, Tokyo, Japan; 2. Graduate School of Human Health Science, Tokyo Metropolitan University, Tokyo, Japan; 3. Graduate School of Frontier Sciences, University of Tokyo, Chiba, Japan; 4. Graduate School of Engineering, Kyushu University, Fukuoka, Japan*

GO-14. Discriminative detection of extracellular and intracellular sodiums in nerve fibers by magnetic resonance spectroscopy. *S. Yamaguchi-Sekino¹, H. Tatsuoka², M. Sekino³, H. Ohsaki³, Y. Abe¹ and S. Ueno⁴ 1. Department of Biomedical Engineering, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan; 2. Research Center for Frontier Medical Engineering, Chiba University, Chiba, Japan; 3. Department of Advanced Energy, Graduate School of Frontier Sciences, The University of Tokyo, Chiba, Japan; 4. Department of Applied Quantum Physics, Graduate School of Engineering, The Kyusyu University, Fukuoka, Japan*

GO-15. Detection of single Magnetic bead using Spin Valve Structure for an Array of PHR Sensor. *S. Oh¹, H. Tran Quang¹, K. Kim¹ and C. Kim¹ 1. Chung nam univ., Daejeon, South Korea*

**THURSDAY
MORNING
9:00**

POLIVALENTE

**Session GP
SWITCHED RELUCTANCE MACHINES
(POSTER SESSION)
Jeremy Hall, Chair**

GP-01. Extraction of design parameters of linear switched reluctance motor based on force calculation. *S. Jang¹, J. Park¹, J. Choi¹ and H. Sung² 1. Electrical Engineering, Chungnam National University, Daejeon, South Korea; 2. Korea Institute of Machinery & Materials, Daejeon, South Korea*

GP-02. Dynamic Analysis of Rotor Eccentricity in Switched Reluctance Motor with Parallel Winding. *L. Jian¹ 1. Electrical Engineering, Dong-A University, Busan, South Korea*

GP-03. Comparison of 12/8 and 6/4 Switched Reluctance Motor: Noise and Vibration Aspects. *L. Jian¹ 1. Electrical Engineering, Dong-A University, Busan, South Korea*

GP-04. Comparison of iron losses in switched reluctance motor with different winding arrangements and switching sequences. *T. Sun¹ and J. Hong¹1. Department of Mechanical Engineering, Hanyang University, Seoul, South Korea*

GP-05. Optimum Design Criteria for Maximum Torque Density and Minimum Torque Ripple of Synchronous Reluctance Motor according to the Rated Wattage using Response Surface Methodology. *Y. Choi¹ and S. Mun¹1. Electrical Eng., Hanbat National University, Daejeon, South Korea*

GP-06. The Evaluation of On-line Observer System of Synchronous Reluctance Motor Using a Coupled FEM & Preisach Model. *H. Lim¹, J. Lee¹, M. Lee¹ and D. Lee²1. Electrical Engineering, Hanbat National University, Daejeon, South Korea; 2. Electrical Engineering, Hanyang University, Seoul, South Korea*

GP-07. Design and Characteristic Analysis of Synchronous Reluctance Motors with Axial Lamination Rotor. *S. Hahn¹, J. Hong¹, J. Kim¹ and D. Koo²1. Department of Electrical Engineering, Dong-A University, Busan, South Korea; 2. Mechatronics Research Group, Korea Electrotechnology Research Institute, Changwon, South Korea*

GP-08. Design Solutions To Minimize Iron Core Loss In Synchronous Reluctance Motors Using Preisach Model & Finite Elements Method(FEM). *H. Lim¹, J. Lee¹, M. Lee¹ and D. Lee²1. Hanbat National University, Daejeon, South Korea; 2. Electrical Engineering, Hanyang University, Seoul, South Korea*

GP-09. Optimum Design of Synchronous Reluctance Motors Based on Torque/Volume Using Finite Element Method & Sequential Unconstrained Minimization Technique. *S. Mun¹ and Y. Cho¹1. Electrical Engineering, Hanbat National University, Daejeon, South Korea*

GP-10. Reduced windage loss rotor of SRM using magnetic saturation for high speed application. *S. Won¹ and J. Lee¹1. Electrical Eng., Hanyang University, Seoul, South Korea*

GP-11. Calculation of force characteristics of an electromechanical system using co-energy. *M. Hadziselimovic^{1,2}, P. Virtic¹, G. Stumberger^{1,2}, T. Marcic¹ and B. Stumberger^{1,2}1. University of Maribor, FE&CS, Maribor, Slovenia; 2. TECES, Maribor, Slovenia*

GR-02. Surface magnetic properties and depth sensitivity of as-quenched FeNbB ribbons. *O. Zivotsky¹, K. Postava¹, L. Kraus², K. Hrabovska¹ and J. Pistora¹1. Department of Physics, VSB-Technical University of Ostrava, Ostrava, Czech Republic; 2. Institute of Physics, Academy of Sciences of the Czech. Rep., Prague, Czech Republic*

GR-03. Some Magnetic Properties of Bulk Amorphous Fe-Co-Zr-Hf-Ti-W-B-(Y) Alloys. *M. Hasiak¹, K. Sobczyk², J. Zbroszczyk², W. Ciurzynska², J. Olszewski², M. Nabialek², J. Kaleta¹, J. Swierczek² and A. Lukiewska²1. Institute of Materials Science and Applied Mechanics, Wroclaw University of Technology, Wroclaw, 50-370, Poland; 2. Institute of Physics, Czestochowa University of Technology, Czestochowa, 42-200, Poland*

GR-04. Magnetic properties of as - quenched Fe87-xZr3.5Nb3.5B6Cux nanocrystalline ribbons. *J. Hu¹, B. Li², H. Qin¹, R. Zhang¹ and M. Jiang¹1. Department of Physics, Shandong University, Jinan, China; 2. Central Iron & Steel Research Institute, Beijing, China*

GR-05. Dynamics of the magnetic susceptibility of milled Fe_xAl_{100-x} (x = 70,71) alloys. *D. Alba Venero², R. Rodríguez García², L. Fernández Barquín², E. Apiñaniz¹, J.J. Garitaonandia¹ and F. Plazaola¹1. University of the Basque Country, Bilbao, Spain; 2. Universidad de Cantabria, CITIMAC, Santander, Spain*

GR-06. EXAFS studies and magnetic behavior of FeCuZr Ball-milled alloys. *A. Martínez¹, J.J. Romero¹, G. Castro², A. Yang³, V.G. Harris³, J.C. Woicik⁴, A. Hernando¹ and P. Crespo¹1. Intituto de Magnetismo Aplicado, Las Rozas, Madrid, Spain; 2. Sp-line European Synchrotron Radiation Facility, ESRF, Grenoble, France; 3. Northeastern University, Boston, MA; 4. National Institute of Science and Technology, Gaithersburg, MD*

GR-07. Mossbauer and structural studies of the system FeAlNb prepared by mechanical alloying. *L.E. Zamora^{1,3}, G.A. Perez Alcazar^{1,3}, J.M. Greneche² and J.M. Gonzalez³1. Fisica, Universidad del Valle, Cali, Valle, Colombia; 2. Laboratoire de Etat Condense, Université du Maine, 72085, Cedex 9, Le Mans, France; 3. Unidad Asociada, ICMM-IMA, Apdo. 155, 28230 Las Rozas, Madrid, Madrid, Spain*

GR-08. Magnetic and structural characterization of mechanically alloyed Fe50Co50 samples. *G.A. Pérez Alcázar¹, L.E. Zamora Alfonso¹, J.F. Marco², J.J. Romero³, J.M. Gonzalez⁴ and F.J. Palomares³1. Physics, Universidad del Valle, Cali, Valle, Colombia; 2. Instituto de Física-Química Rocasolano, CSIC, C/Serano, 119. 28006, Madrid, Madrid, Spain; 3. Instituto de Magnetismo Aplicado, UC, P.O. Box 155, 28360, Las Rozas, Madrid, Madrid, Spain; 4. Unidad Asociada, ICMM-IMA, P.Box 155, 28360, Las Rozas, Madrid, Madrid, Spain; 5. Instituto de Ciencia de Materiales de Madrid, CSIC, C/Sor Juana Inés de la Cruz, 28049, Cantoblanco, Madrid, Madrid, Spain*

GR-09. Residual strain induced in a crystal lattice upon annealing under stretching load in soft-magnetic Fe-based nanocrystalline alloys. *N.V. Ershov¹, Y.P. Chernenkov², V.I. Fedorov², V.A. Lukshina¹ and A.P. Potapov¹1. Institute of Metal Physics, Ural Division, Russian Academy of Sciences, Yekaterinburg, Russian Federation; 2. St.-Petersburg Institute of Nuclear Physics, Russian Academy of Sciences, Gatchina, Russian Federation*

GR-10. Magnetic properties and reaction kinetics of synthesized Fe-Ni-Co alloy during H₂ reduction of Ni_{0.5}Co_{0.5}Fe₂O₄. *M. Bahgat¹, M. Paek¹ and J. Pak¹1. Metallurgical and material engineering, Hanyang university, Ansan, South Korea*

THURSDAY
MORNING
9:00

POLIVALENTE

Session GR SOFT NANOCRYSTALLINE ALLOYS (POSTER SESSION)

Daichi Azuma, Chair
Patricia Crespo, Chair

GR-01. Exchange bias in surface-crystalline FeNbB ribbons. *L. Kraus¹, O. Zivotsky², K. Postava², P. Svec³ and D. Janičkovič³1. Institute of Physics v.v.i., Academy of Sciences of the Czech Republic, Prague, Czech Republic; 2. Department of Physics, Technical University of Ostrava, Ostrava, Czech Republic; 3. Institute of Physics, Slovak Academy of Sciences, Bratislava, Slovakia*

GR-11. Magnetocaloric effect in the FeCrCuNbSiB amorphous materials. *A. Kolano-Burian¹, M. Kowalczyk², R. Kolano¹, R. Szymczak³, H. Szymczak³, T. Kulik² and J. Szynowski¹* *1. Institute of Non-Ferrous Metals, Gliwice, Poland; 2. Faculty of Materials Science and Engineering, Warsaw University of Technology, Warsaw, Poland; 3. Institute of Physics, Polish Academy of Sciences, Warsaw, Poland*

GR-12. Thermal and magnetic field-induced martensite-austenite transformation in melt spun Mn₅₀Ni₄₀In₁₀ ribbons. *J.L. Sanchez Llamazares¹, B. Hernando¹, J.D. Santos¹, M.J. Pérez¹, C. García², J. González² and R. Varga³* *1. Departamento de Física, Universidad de Oviedo, Oviedo, Asturias, Spain; 2. Departamento de Física de Materiales, Universidad del País Vasco, San Sebastián, Spain; 3. Institute of Physics, UPJS, Kosice, Slovakia*

GR-13. Influence of the Fe/B ratio on the magnetocaloric response of Fe_{92-x}Cr₈B_x (x=12, 15) amorphous alloys. *V. Franco¹, A. Conde¹ and L.F. Kiss²* *1. Department of Condensed Matter Physics, Sevilla University, Sevilla, Spain; 2. Research Institute for Solid State Physics and Optics, Hungarian Academy of Sciences, Budapest, Hungary*

GR-14. XMCD-PEEM imaging of the micromagnetic structure of Co₂FeSi Heusler compound. *A. Gloskovskii¹, C. Blum¹, J. Barth¹, G. Fecher¹, P. Nagel², S. Schuppler², G. Schönhense³ and C. Felser¹* *1. Institut für Anorganische Chemie und Analytische Chemie, Johannes Gutenberg - Universität, Mainz, Germany; 2. Forschungszentrum Karlsruhe, Institut für Festkörperphysik, Karlsruhe, Germany; 3. Institut für Physik, Johannes Gutenberg - Universität, Mainz, Germany*

GR-15. Transport and Magnetism in Nd₅Si_{1.45}Ge_{2.55} *A.M. Pereira¹, C. Magen⁴, P. Algarabel², L. Morellón^{2,3}, M.E. Braga¹, F. Carpinheiro¹, M.R. Ibarra^{2,3}, J. Ventura¹, J.B. Sousa¹ and J.P. Araujo¹* *1. IFIMUP Faculdade de Ciências da Universidade do Porto, Porto, Portugal; 2. ICMA - Universidad de Zaragoza and Consejo Superior de Investigaciones Científicas, Zaragoza, Spain; 3. Instituto de Nanociencia de Aragón, Universidad de Zaragoza, Zaragoza, Spain; 4. Oak Ridge Natl Lab, High Temp Mat Lab, Oak Ridge, TN*

GR-16. Magnetism and phase transformation in Fe / Fe oxide milled nanopowders. *O. Crisan¹, R. Nicula² and I. Skorvanek³* *1. National Institute for Materials Physics, Bucharest-Magurele, Romania; 2. Institute of Physics, Rostock University, Rostock, Germany; 3. Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovakia*

GR-17. Magnetic properties of high Bs Fe-based amorphous powders produced by Spinning Water Atomization Process (SWAP). *I. Otsuka¹, K. Wada¹, Y. Maeta¹, T. Kadamura¹ and M. Yagi²* *1. EPSON AT MIX CORPORATION, Hachinohe-shi, Aomori-ken, Japan; 2. Sojo University, Kumamoto, Japan*

GR-18. Study on the microstructure and soft magnetic properties of Ni-Fe particles synthesized by a conventional and a microwave-assisted polyol method. *Y. Shimada¹, Y. Endo¹, S. Okamoto², M. Yamaguchi¹ and O. Kitakami^{2,3}* *1. Dept. of Electrical and Communication Engineering, Tohoku University, Sendai, Japan; 2. IMRAM, Tohoku Univ., Sendai, Japan*

GR-19. Synthesis, Phase Transfer and Magnetic Properties of Monodisperse Magnetite Nanocubes. *H. Yang¹, D. Hasegawa², M. Takahashi¹ and T. Ogawa^{2,3}* *1. Niche, Tohoku University, Sendai, Miyagi, Japan; 2. Dep. of Electronics Engineering, Tohoku University, Sendai, Miyagi, Japan; 3. Cress, Tohoku University, Sendai, Miyagi, Japan*

GR-20. Size controlled Fe nanoparticles through polyol process and their magnetic properties. *R.J. Joseyphus^{1,2}, K. Shinoda², D. Kodama² and B. Jeyadevan²* *1. Department of Physics, National Institute of Technology, Tiruchirappalli, Tamilnadu, India; 2. Graduate School of Environmental Studies, Tohoku University, Sendai, Miyagi, Japan*

GR-21. Magnetic behaviour of Gd₄(Co_{1-x}Cu)₃ compounds. *T.M. Seixas^{1,2}, M.A. Salgueiro da Silva², J.M. Machado da Silva^{1,2}, H.F. Braun³ and G. Eska³* *1. Instituto de Física dos Materiais da Universidade do Porto (IFIMUP), Porto, Portugal; 2. Departamento de Física da Universidade do Porto, Rua do Campo Alegre, 687, 4169-007, Porto, Portugal; 3. Physikalisches Institut, Universitaet Bayreuth, D – 95440, Bayreuth, Germany*

GR-22. Exact Calculation of The Magnetostatic Interaction in Arrays of Nanowires. *J. Velázquez¹* *1. CAI Difracción Rayos X, Universidad Complutense de Madrid, Madrid, Spain*

**THURSDAY
MORNING
9:00**

POLIVALENTE

Session GS POWER AND CONTROL MAGNETICS (POSTER SESSION)

David Howe, Chair

GS-01. Performance Analysis of Flyback Converter Based on Time-stepping FEA Incorporating Magnetic Hysteresis Effect. *J. Chen¹, Y. Guo², J. Zhu² and Z. Lin²* *1. College of Electromechanical Engineering, Donghua University, Shanghai, Shanghai, China; 2. Faculty of Engineering, University of Technology Sydney, Sydney, NSW, Australia*

GS-02. Chaoization of Permanent Magnet Synchronous Motors Using Stator Flux Regulation. *Z. Wang¹ and K. Chau¹* *1. Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, China*

GS-03. Fundamental Resarch about Parameter Design of Contactless Power Station for Moving Electric Loads. *N. Nakajima¹, Y. Kakubari¹, F. Sato¹ and H. Matsuki¹* *1. Tohoku University, Sendai, Miyagi, Japan*

GS-04. Experimental Verification and Performance Analysis of Permanent Magnet Wind Turbine Generators considering Magnetic Losses using D-Q Axis Model. *S. Jang¹, J. Choi¹, K. Ko¹ and B. Kim²* *1. Chungnam National University, Dae-jeon, South Korea; 2. Korea Electric Power Research Institute, Daejeon, South Korea*

GS-05. Design, Fabrication and Experimental Validation of a Miniaturized Generator with Planar Coils via Genetic Algorithm. *P. Chao¹, J. Shen², E. Chiu¹ and J. Huang²* *1. Electrical and Control Engineering, National Chiao Tung University, Hsinchu, Taiwan; 2. Mechanical Engineering, Chung Yuan Christian Univ., Chung Li, Taiwan*

GS-06. Electromagnetic Analysis and Parameter Estimation of Permanent Magnet Wind Turbine Generators Considering Skew Effects. S. Jang¹, J. Choi¹ and K. Ko¹. *1. Chungnam National University, Dae-jeon, South Korea*

GS-07. Operating time estimation in acceleration and deceleration mode of high power FESS using electromagnetic field analysis of PM synchronous motor/generator. D. You¹, S. Jang¹, J. Lee² and T. Sung². *1. chungnam national univ., daejeon, South Korea; 2. Korea Electric Power Research Institute, Daejeon, South Korea*

GS-08. Magnetic Switch Topologies. W. Johnson¹. *1. Electrical and Computer Engineering, University of Kentucky, Lexington, Ky, KY*

THURSDAY
MORNING
9:00

POLIVALENTE

Session GT
**SPIN TORQUE EXCITATIONS IN NANOMAGNETS
(POSTER SESSION)**

Dafine Ravelosona, Chair

GT-01. Influence of Notch Shape and Size on Current-Driven Domain Wall Motions in a Magnetic Nanowire. H. Murakami¹, T. Komine¹, T. Nagayama¹, R. Sugita¹ and Y. Hasegawa². *1. Department of Media and Telecommunications Engineering, Ibaraki University, Hitachi, Ibaraki, Japan; 2. Saitama University, Saitama, Saitama, Japan*

GT-02. Multi-level transitions of closely-arranged spin valve pillars by spin transfer switching. N. Funabashi¹, K. Machida¹, K. Aoshima¹, Y. Miyamoto¹, N. Kawamura¹, K. Kuga¹ and N. Shimidzu¹. *1. NHK Science & Technical Research Laboratories, Tokyo, Japan*

GT-03. Dependence of current induced switching properties on MgO formation method. J. Langer¹, J. Wrona¹, B. Ocker¹, W. Maass¹, A. Thomas², K. Rott², M. Schaefer² and G. Reiss². *1. Singulus Nano Deposition Technologies GmbH, Kahl am Main, Germany; 2. Department of Physics, Bielefeld University, Bielefeld, Germany*

GT-04. Dynamics of current-induced magnetic switching of a single-molecule magnet. M. Misiorny¹ and J. Barnas^{1,2}. *1. Department of Physics, Adam Mickiewicz University, Poznan, Poland; 2. Institute of Molecular Physics, Polish Academy of Science, Poznan, Poland*

GT-05. Spin mechatronics to facilitate spin transfer switching in magnetic tunnel junction. S. Kumar^{1,2}, N. Chen¹, S. Tan¹ and M. Jalil². *1. SMI, Data Storage Institute, Singapore, Singapore; 2. ISML, ECE, National University of Singapore, singapore, Singapore*

GT-06. Spin transfer in Co/Cu/Co nanocontacts. M.N. Baibich¹, M.P. de Lucena¹, D.L. Baptista¹, R.B. da Silva¹, J.E. Schmidt¹ and L.G. Pereira¹. *1. Instituto de Física UFRGS, Porto Alegre, RS, Brazil*

GT-07. On the relation of the inelastic spin torque and the spin polarization. W. Wulfhchel¹, A.F. Takacs¹, T. Balashov¹, M. Däne², A. Ernst² and P. Bruno². *1. Physikalisches Institut, Universität Karlsruhe, Karlsruhe, Germany; 2. Max-Planck Institut für Mikrostrukturphysik, Halle, Germany*

GT-08. Microscopic theory of spin transfer torque based on the spin spiral texture. Y. Le Maho¹ and F. Piechon². *1. Institut d'Electronique Fondamentale, CNRS / Univ. Paris Sud, Orsay, Paris, France; 2. Laboratoire de Physique des Solides, CNRS / Univ. Paris Sud, Orsay, Paris, France*

GT-09. Current-induced domain wall motion in permalloy nanowires. W. Zhang¹, P. Wong¹, Y. Xu¹, X. Zou² and J. Wu². *1. Spintronics and Nanodevice Laboratory, Department of Electronics, University of York, York, United Kingdom; 2. Department of Physics, University of York, York, United Kingdom*

GT-10. Spin transfer switching in magnetic tunnel junction using a composite free layer. W. Chen¹, D. Wang¹, C. Yen¹, Y. Lee¹, S. Yang¹, C. Shen¹, C. Tsai¹, C. Hung¹, K. Shen¹ and M. Kao¹. *1. Electronics and Optoelectronics Research Lab. (EOL), Industrial Technology Research Institute (ITRI), Hsinchu, Taiwan*

GT-11. Current-induced Domain Wall Motion in L- and C-shaped Permalloy Nanowires. J. Yoon^{1,4}, J. Lee^{2,3}, C. You⁴, S. Choe³, K. Shin² and M. Jung¹. *1. Quantum Material Research Team, Korea Basic Science Institute, Daejeon, South Korea; 2. Center for Spintronics Research, Korea Institute of Science and Technology, Seoul, South Korea; 3. physics, Seoul National University, Seoul, South Korea; 4. physics, Inha University, Incheon, South Korea*

GT-12. Experimental study of thermally activated magnetization reversal with a spin-transfer torque in a nanowire. K. Seon Ock¹, W. Kim¹, T. Lee¹, K. Kim², S. Choe², Y. Jang³, S. Yoon³ and B. Cho³. *1. Department of Materials Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, South Korea; 2. Department of Physics and Astronomy, Seoul National University, Seoul, South Korea; 3. Department of Materials Science and Engineering, Gwangju Institute of Science and Technology, Gwangju, South Korea*

GT-13. Spin-Transfer Switching in Elliptical Spin Valves in Subnanosecond Regime. R. Heindl¹, T. Silva¹, W. Rippard¹, S. Russek¹ and J. Katine². *1. Electromagnetics Division - Magnetics Group, National Institute of Standards and Technology (NIST), Boulder, CO; 2. Hitachi San Jose Research Center, San Jose, CA*

GT-14. Shape dependence of current-induced magnetization switching. C. Tsai¹, Y. Lee¹, D. Wang¹, W. Chen¹, C. Yen¹, C. Shen¹, S. Yang¹, C. Hung¹, K. Shen¹ and M. Kao¹. *1. Electronics and Optoelectronics Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan*

GT-15. Static and Dynamic Depinning Current Density in Current-Induced Domain Wall Motion. S. Seo¹, H. Lee², W. Kim³, T. Lee³, S. Choe⁴, D. Kim⁵ and K. Lee⁵. *1. Korea University, Seoul, South Korea; 2. POSTECH, Pohang, South Korea; 3. KAIST, Daejeon, South Korea; 4. Seoul National University, Seoul, South Korea; 5. Chungbuk National University, Cheongju, South Korea*

GT-16. Current-assisted variation of magnetization reversal process in tri-layer-ring spin valve. D. Chen¹, C. Yu² and Y. Yao^{1,3}. *1. Department of Material Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan; 2. Institute of Physics, Academia Sinica, Taipei, Taiwan; 3. The Department of Materials Engineering, Tatung University, Taipei, Taiwan*

GT-17. Domain wall dynamics in the microwave frequency range probed by Spin diode effect. S. Laribi^{1,2}, A. Anane¹, J. Grollier¹, V. Cros¹, K. Bouzehouane¹, G. Faini³ and A. Fert¹. *Unité Mixte de Physique CNRS/Thales and Université Paris Sud 11, Route départementale 128, 91767, Palaiseau, France; 2. ST Microelectronics, 850 Rue Jean Monnet, 38926, Crolles, France; 3. Phynano team, Laboratoire de Photonique et Nanostructures, LPN-CNRS, Route de Nozay, 91460, Marcoussis, France*

GT-18. Current induced domain wall motion with step structure. H. Ashida¹, T. Ochiai¹, Y. Shimizu¹ and A. Tanaka¹. *Fujitsu Limited., Atsugi, 243-0197, Japan*

Session GU MAGNETOCALORIC EFFECT AND MATERIALS (POSTER SESSION)

Julia Lyubina, Chair

GU-01. Magnetocaloric Effect in Ni-Mn-Ga Alloys. K. Mandal¹, D. Pal¹, O. Gutfleisch², J. Lyubina² and N. Scheerbaum². *1. Materials Science, S. N. Bose National Centre for Basic Sciences, Kolkata, West Bengal, India; 2. Institut für Metallische Werkstoffe, Leibniz Institute für Festkörper- und Werkstoffforschung Dresden (IFW Dresden), Dresden, saxony, Germany*

GU-02. Magnetic properties and magnetocaloric effect in Tb₈Co_{16-x}A_x compounds where A=Al or Cu and x ≤ 4. R. Tetean¹, E. Burzo¹ and I.G. Deac¹. *1. Physics, Babes-Bolyai University, Cluj Napoca, Romania*

GU-03. Synthesis and evaluation of magnetocaloric effect of rare earth nitrides. Y. Hirayama¹, S. Nishio¹, T. Kusunose², T. Nakagawa³ and T.A. Yamamoto¹. *1. Graduate School of Engineering, Osaka University, Osaka, Japan; 2. Institute of Scientific and Industrial Research, Osaka University, Osaka, Japan; 3. Graduate School of Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan*

GU-04. Anisotropy of magnetocaloric effect in R₂Fe₁₇ single crystals with heavy RE metals and Y. K.P. Skokov¹, Y.G. Pastushenkov¹, Y.S. Koshkid'ko¹, T.I. Ivanova² and S.A. Nikitin². *1. Department of Physics, Tver State University, Tver, Russian Federation; 2. Department of Physics, Moscow State University, Moscow, Russian Federation*

GU-05. Magnetocaloric effect in Gd₄(Bi_xSb_{1-x})₃ alloys. N.A. de Oliveira¹ and M.B. Gomes¹. *1. Instituto de Física, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil*

GU-06. Magnetocaloric effect in La(Fe_xSi_{1-x})₁₃ under applied pressure. N.A. de Oliveira¹, L.G. de Medeiros Jr¹ and A. Troper^{1,2}. *1. Instituto de Física, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil; 2. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brazil*

GU-07. Magnetocaloric Effect of the PrNi₅-xCox Hard Magnets. D.L. Rocco¹, R.P. Fernandes², M.S. Reis¹, J.S. Amaral¹, V.S. Amaral¹, J.P. Araújo³, P.B. Tavares⁴ and A.A. Coelho⁵. *1. Departamento de Física e CICECO, Universidade de Aveiro, Aveiro, Portugal; 2. Technische Universität Hamburg-Harburg, Institut für Keramische Hochleistungswerkstoffe, Hamburg, Germany; 3. IFIMUP, Departamento de Física, Universidade do Porto, Porto, Portugal; 4. Departamento de Química and CQ-VR, Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal; 5. Departamento de Física Gleb Wataguin, Universidade Estadual de Campinas – UNICAMP, Campinas, Brazil*

Session GV FAST SWITCHING OF FILMS AND NANOSTRUCTURES (POSTER SESSION)

Karsten Kuepper, Chair

GV-01. Laser induced magnetisation switching in films with perpendicular anisotropy: a comparison between measurements and an LLB macro-spin model. C. Bunce¹, J. Wu¹, G. Ju², B. Lu², D. Hinzke¹, N. Kazantseva¹, R. Chantrell¹ and U. Nowak¹. *1. Department of Physics, University of York, York, United Kingdom; 2. Seagate Research, 1251 Waterfront Place, Pittsburgh, PA*

GV-02. Spin dynamics in patterned nanoscale Fe dot arrays. J. Wu¹, S. Lepadatu¹, C. Bunce¹, X. Zou¹, D. Niu², Y.B. Xu², R. Chantrell¹ and G.P. Ju³. *1. Physics, University of York, York, United Kingdom; 2. Electronics, University of York, York, United Kingdom; 3. Seagate Research, Pittsburgh, PA*

GV-03. FMR study of self-organized plane arrays of metallic magnetic elements. M. Kostylev¹, R. Magaraggia¹, F.Y. Ogrin², V. Mescheryakov^{3,4}, N. Ross¹ and R.L. Stamps¹. *1. School of Physics, University of Western Australia, Crawley, WA, Australia; 2. School of Physics, University of Exeter, Exeter, United Kingdom; 3. Moscow Institute of Radioelectronics and Automation, Moscow, Russian Federation; 4. Institute of Crystallography of Russian Academy of Science, Moscow, Russian Federation*

GV-04. Complex broadband magnetic response of periodic arrays of FeNi dots and of Fe/Cr multilayers studied by using FMR-VNA technique. J. Sierra¹, A. Awad¹, V. Pryadun¹, F. Aliev¹ and G. Kakazei². *1. Departamento de Física de la Materia Condensada, Universidad Autonoma de Madrid, Spain, Madrid, Spain; 2. Institute of Magnetism NASU, Kiev, Ukraine*

GV-05. Linear and Nonlinear Dynamics of the Gyrotropic Motion of a Magnetic Vortex in Ferromagnetic Nanodots. K. Lee¹ and S. Kim¹. *1. Research Center for Spin Dynamics and Spin-Wave Devices & Nanospintronics Laboratory, Seoul National University, Seoul, South Korea*

GV-06. Nonlinear phenomena in magnetic nanoparticle systems at microwave frequencies. M. Pardavi-Horvath¹, G.S. Makeeva² and O.A. Golovanov³. *1. SEAS, The George Washington University, Washington, DC; 2. Penza State University, Penza, Russian Federation; 3. Penza Military Institute of Artillery, Penza-5, Russian Federation*

GV-07. Parametric spin wave excitation and cascaded processes in thin films. *K. Livesey¹, M. Kostylev¹ and R. Stamps¹ 1. School of Physics, University of Western Australia, Crawley, WA, Australia*

GV-08. Micromagnetic modeling of the magnetization dynamics in a circularly exchange biased tunnel junction. *O.G. Heinonen¹, D.K. Schreiber² and A.K. Petford-Long³ 1. Seagate Technology, Bloomington, MN; 2. Materials Science and Engineering, Northwestern University, Evanston, IL; 3. Materials Science Division, Argonne National Laboratory, Argonne, IL*

GV-09. WITHDRAWN

GV-10. Size dependence of the magnetic switching of Co-nanoislands studied by spin-polarized scanning tunneling spectroscopy. *D. Sander¹, S. Wedekind¹, G. Rodary¹ and K. Jürgen¹ 1. Max Planck Institute, Halle, Germany*

**THURSDAY
MORNING
9:00**

POLIVALENTE

**Session GW
COMPUTATIONAL MAGNETICS
(POSTER SESSION)**

Claudio Serpico, Chair

GW-01. Chemical order and size effects on the magnetic anisotropy of FePt and CoPt nanoparticles. *F. Tournus¹, S. Rohart^{1,2} and V. Dupuis¹ 1. LPMC/N, Université de Lyon; Univ. Lyon 1; CNRS, Villeurbanne, France; 2. LPS, Université Paris Sud; CNRS, Orsay, France*

GW-02. A study of the optimum dose of ferromagnetic nanoparticles suitable for cancer therapy using magnetic fluid hyperthermia. *M. Pavel^{1,2}, G. Gradinariu^{1,2} and A. Stancu¹ 1. Department of Solid State and Theoretical Physics, “Alexandru Ioan Cuza” University, Faculty of Physics, Iasi, Romania; 2. Department of Oncology, University of Medicine and Pharmacy “Gr. T. Popa”, Iasi, Romania*

GW-03. Influence of dipole interaction and thermal effect on static magnetization process of magnetic nanoparticle assembly. *D. Hasegawa¹, T. Ogawa² and M. Takahashi³ 1. Electronic Engineering, Tohoku University, Sendai, Japan; 2. CRESS, Tohoku University, Sendai, Japan; 3. NICHe, Tohoku University, Sendai, Japan*

GW-04. Numerical Modeling and Characterization of Micromachined Flexible Magnetostrictive Thin Film Actuator. *H. Lee¹ and C. Cho¹ 1. Mechanical Engineering, Inha University, Incheon, South Korea*

GW-05. Semi-analytical calculation of the armature reaction in a slotted tubular permanent magnet actuator with distributed windings. *B. Gysen¹, J. Paulides¹, E. Lomonova¹ and A. Vandenput¹ 1. Electrical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands*

GW-06. Sequential optimization method for the design of electromagnetic devices. *G. Lei¹, Y. Guo² and J. Lavers³ 1. College of Electrical and Electronic Engineering, Huazhong University of Science and Technology, Wuhan, HuBei, China; 2. Faculty of Engineering, University of Technology, Sydney, NSW, Australia; 3. Department of Electrical and Computer Engineering, University of Toronto, Toronto, ON, Canada*

GW-07. A new field-circuit coupled method for the computation of additional losses in transformer. *G. Jian¹, L. Heyun¹ and H. Siulau² 1. School of Electrical Engineering, Southeast University, Nanjing, Jiangsu, China; 2. Department of Electrical Engineering, Hong Kong Polytechnic University, Hong Kong, Hong Kong, China*

GW-08. Accurate eddy current losses computation for ferromagnetic cores working in strongly distorted regimes. *L. Mandache¹, D. Topan¹ and K. Al-Haddad² 1. Electrical Engineering, University of Craiova, Craiova, Romania; 2. Genie Electrique, Ecole de Technologie Supérieure, Montreal, QC, Canada*

GW-09. Modeling of effect of plastic deformation on Barkhausen noise and magnetoacoustic emission in iron with 2% silicon. *M.J. Sablik¹, B. Augustyniak² and F.J. Landgraf³ 1. Mechanical and Materials Engineering Div., Bldg. 139,, Southwest Res. Inst., San Antonio, TX; 2. Physics, Gdansk Institute of Technology, Gdansk, Poland; 3. Metallurgical Engineering, University of Sao Paulo, Sao Paulo, Brazil*

GW-10. Fluxmetric and Magnetometric Demagnetizing Factors in Cylindrical and Rectangular Geometries. *A. Vashghani Farahani¹ and A. Konrad¹ 1. Electrical and computer engineering, University of Toronto, Toronto, ON, Canada*

GW-11. Transmutation of momentum into position in magnetic vortices. *S. Komineas¹ and N. Papanicolaou² 1. Max-Planck Institute, Dresden, Germany; 2. Department of Physics, University of Crete, Heraklion, Greece*

GW-12. Reduction Design of Eddy Current Loss in Permanent Magnet. *J. Jung¹, S. Lee¹ and J. Hong¹ 1. Department of Mechanical Engineering, Hanyang University, Seoul, South Korea*

**THURSDAY
MORNING
9:00**

POLIVALENTE

**Session GX
MISCELLANEOUS I
(POSTER SESSION)**
Federico Cebollada, Chair

GX-01. Magnon thermalization and formation of coherent Bose-Einstein condensate. *S.O. Demokritov¹, V.E. Demidov¹, O. Dzyapko¹, G.A. Melkov² and A.N. Slavin³ 1. Institute for Applied Physics, University of Muenster, Muenster, Germany; 2. Department of Radiophysics, National Taras Shevchenko University of Kiev, Kiev, Ukraine; 3. Department of Physics, Oakland University, Rochester, MI*

GX-02. Critical Temperature for Thermal Runaway in a Magnetic Material. F. Farahmand¹, F.P. Dawson¹ and J. Lavers¹. *ECE, The University of Toronto, Toronto, ON, Canada*

GX-03. Effects of double-axis electromagnetic stirring in continuous casting. R. Otake¹, T. Yamada², R. Hirayama³, K. Fujisaki^{1,3}, S. Shimasaki¹ and S. Taniguchi¹. *Graduate school of TOHOKU university, Sendai, Japan; 2. Nittetsu Plant Designing Corp., Futtsu, Japan; 3. Nippon Steel Corp., Futtsu, Japan*

GX-04. Diamagnetic levitation of solids at micro scale. C. Pigo¹, G. Poulin¹ and R. Gilbert¹. *Magnetic Microsystems, G2ELab, Grenoble, France*

GX-05. Construction of Quasi-Cyclic LDPC Codes and the Performance over Magnetic Recording Channels. X. Liu¹, H. Cheng¹ and Z. Wang². *Dept. of Electronics & Comm. Engr., Sun Yat-Sen University, Guangzhou, Guangdong, China; 2. School of Electrical Engineering and Computer Science, Oregon State University, Corvallis, OR*

GX-06. A Novel Electromagnetic Device for Latching Valve in Automotive Engine. J. Kim¹ and J. Chang². *1. Mechanical Engineering, Yeungnam University, Gyeongsan, Gyeongsangbuk-do, South Korea; 2. Transverse Flux Machines Research Group, Korea Electrotechnology Research Institute, Changwon, Kyungsangnam-Do, South Korea*

GX-07. Air gap's influence on the performance of the transformer of an electromagnetic pump. D. Morinigo^{2,1}, M.A. Rodríguez^{1,2}, A. Rivas¹ and J. Martín¹. *1. Light Alloys, CIDAUT Foundation, Valladolid, Spain; 2. Electrical Engineering, University of Valladolid, Valladolid, Spain*

GX-08. A New Calibration Procedure for Magnetic Tracking Systems. A. Plotkin¹, V. Kucher¹, Y. Horen² and E. Paperno¹. *1. Electrical and Computer Engineering, Ben-Gurion University of the Negev, Beer-Sheva, Israel; 2. Electrical and Electronic Engineering, Shamoon College of Engineering, Beer-Sheva, Israel*

GX-09. Microstructural changes in Fe-doped Gd₅Si₂Ge₂. B. Podmiljsak¹, I. Skulj², B. Markoli³, P. McGuinness¹ and S. Kobe¹. *1. Jozef Stefan Institute, Ljubljana, Slovenia; 2. Institute of Metals and Technology, Ljubljana, Slovenia; 3. University of Ljubljana, Ljubljana, Slovenia*

GX-10. Stress-strain relationship of magnetorheological fluids under tension mode. S.A. Mazlan¹, N.B. Ekreem¹ and A.G. Olabi¹. *School of Mechanical and Manufacturing Engineering, Dublin City University, Dublin, Ireland*

GX-11. Novel magnetic composite particles of carbonyl iron embedded in polystyrene and their magnetorheological characteristics. F. Fang¹ and H. Choi¹. *Department of Polymer Science and Engineering, Inha University, Incheon, South Korea*

GX-12. Barkhausen noise statistical properties in ferromagnetic thin films: dimensionality and range of the relevant interactions. F. Bohn¹, M.A. Corrêa^{2,1}, A. Viegas³, L.F. Schelp¹ and R.L. Sommer⁴. *1. Departamento de Física, Universidade Federal de Santa Maria, Santa Maria, RS, Brazil; 2. Campus Caçapava do Sul, Universidade Federal do Pampa, Caçapava do Sul, RS, Brazil; 3. Departamento de Física, Universidade Federal de Santa Catarina, Florianópolis, SC, Brazil; 4. Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, RJ, Brazil*

**THURSDAY
MORNING
9:00**

POLIVALENTE

**Session GY
MISCELLANEOUS II
(POSTER SESSION)
Puerto Morales, Chair**

GY-01. Coloring media by using nanopipette to store more data. M. Rashidi¹ and F. Wang¹. *Centre for Grid Computing, Cambridge-Cranfield HPCF, Cranfield, United Kingdom*

GY-02. AFM friction investigation with temperature. D. Kim¹. *Samsung Information Systems America, Inc, San Jose, CA*

GY-03. Arsenic Removal from Water by Magnetic Separation: A Review and a Case Study Using Magnetic Aggregates and Magnetic Stabilized Bed. A.M. Estevez¹, P.A. Augusto^{2,1}, J.M. Rodriguez¹ and A. Alvaro¹. *1. Department of Chemical Engineering, University of Salamanca, Salamanca, Castilla y Leon, Spain; 2. DEQ, Faculdade de Engenharia da Universidade do Porto, Porto, Portugal*

GY-04. Investigation of Nanoparticle Clusterization in Magnetic Fluids Driven by Surface-Coating Desorption. F.M. Oliveira¹, P.C. Morais¹, K.S. Neto¹, A.P. Canizares¹ and L.C. Figueiredo¹. *Instituto de Física, Universidade de Brasília, Brasília, Brasília/DF, Brazil*

GY-05. Detection of Low-Concentration Magnetic Fluid inside Body by Needle-Type GMR Sensor. S. Yamada¹, C.P. Gooneratne¹, M. Iwahara¹ and M. Kakikawa¹. *Institute of Nature and Environmental Technology, Faculty of Engineering, Kanazawa University, Kanazawa, Ishikawa, Japan*

GY-06. Suppression of electromyogram of hand muscle elicited by transcranial magnetic stimulation over the primary motor cortex. M. Odagaki¹, S. Ohishi¹, H. Fukuda¹ and O. Hiwaki¹. *Graduate School of Information Sciences, Hiroshima City University, Hiroshima, Japan*

GY-07. Formation of beta-Sheet Rich Fibrils in Cortex Cells from Mice Fetuses Cultured with Ferritin and Exposed to Radio Frequency Magnetic Fields. O. Cespedes¹, O. Inomoto¹, S. Kai¹ and S. Ueno¹. *Applied Quantum Physics Department, Kyushu University, Fukuoka, Japan*

GY-08. Effects of Radio Frequency Magnetic Fields on the Iron Release from Cage Proteins via 6-Hydroxydopamine. O. Cespedes¹ and S. Ueno¹. *Applied Quantum Physics Department, Kyushu University, Fukuoka, Japan*

GY-09. Short and long duration of rTMS effects on perceptual reversals. S. Ge¹, T. Hayami², A. Hyodo³, S. Ueno⁴ and K. Iramina^{1,3}. *1. Department of Intelligent Systems, Kyushu University, Fukuoka, Japan; 2. Digital Medicine Initiative, Kyushu University, Fukuoka, Japan; 3. Graduate School of Systems Life Sciences, Kyushu University, Fukuoka, Japan; 4. Department of Applied Quantum Physics, Kyushu University, Fukuoka, Japan*

AFTERNOON
2:30

AUDITORIO A

THURSDAY
AFTERNOON
2:30

MADRID

Session HA

SYMPOSIUM ON THE ROADMAP FOR SPINTRONICS

Yongbing Xu, Chair
Atsufumi Hirohata, Chair

2:30

HA-01. Prospects for Spin Memory Devices and Their Element Technologies in the Next 10 Years. (Invited) S. Nakamura¹. *Corporate R&D Center, Toshiba Corporation, Kawasaki, Japan*

3:00

HA-02. Spintronics devices based on the Tunneling Anisotropic Magnetoresistance and the Coulomb Blockade Anisotropic Magnetoresistance effect. (Invited) J. Wunderlich^{1,2}, B. Park¹, A.C. Irvine³, A. Shick², R.P. Campion⁴, V. Novak², D.A. Williams¹, B.L. Gallagher⁴ and T. Jungwirth^{2,4}. *1. Hitachi Europe Ltd., Hitachi Cambridge Laboratory, Cambridge, United Kingdom; 2. Institute of Physics ASCR, Prague, Czech Republic; 3. Microelectronics Research Centre, University of Cambridge, Cambridge, United Kingdom; 4. School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom*

3:30

HA-03. Engineering magnetic nanostructures into complex devices for spin electronics. (Invited) C. Chappert^{1,2}. *1. IEF, CNRS - UMR 8622, Orsay, France; 2. IEF, Université Paris Sud, Orsay, France*

4:00

HA-04. Manipulating single spins and coherence for semiconductor spintronics. (Invited) D.D. Awschalom¹. *Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA*

4:30

HA-05. The road to silicon spintronics. (Invited) R. Jansen¹. *MESA+ Institute for Nanotechnology, University of Twente, Enschede, Netherlands*

5:00

HA-06. Spin Manipulation in Semiconductors and Metals. (Invited) H. Ohno^{1,2}. *1. Laboratory for Nanoelectronics and Spintronics, Research Institute of Electrical Communication, Tohoku University, Sendai, Japan; 2. ERATO, JST, Sendai, Japan*

Session HB

INDUCTIVE RECORDING HEADS AND MATERIALS

Alan Johnston, Chair

2:30

HB-01. Micromagnetic Model Analysis of a Single-Pole-Type Head for 1 – 2 Tbit/in² Y. Kanai¹, K. Hirasawa¹, T. Tsukamoto¹, K. Yoshida², S. Greaves³ and H. Muraoka³. *1. Niigata Institute of Technology, Kashiwazaki, Japan; 2. Kogakuin University, Tokyo, Japan; 3. Tohoku University, Sendai, Japan*

2:45

HB-02. 1 Turn Solenoid PMR Writer Design for High Frequency Writing. E. Kim¹ and K. Sunwoo¹. *HDD Core Tech TF, Samsung Advanced Institute of Technology, Yongin, Kyongki-Do, South Korea*

3:00

HB-03. Advanced heads for areal density at 500Gb/in² and towards 1Tb/in². (Invited) M. Ho¹, S. Mao¹, S. Li¹, L. Zhong¹, E. Champion¹, S. Song¹, J. Wang¹, T. Pan¹, K. Stoev¹, C. Macchioni¹, Y. Chen¹, L. Wang¹, Q. Leng¹, M. Pakala¹, Y. Li¹, U. Tran¹, M. Chapline¹, W. Yu¹, L. Hong¹, D. Li¹ and Y. Shen¹. *Western Digital Corp, Fremont, CA*

3:30

HB-04. Writing performance of a planar single-pole head with a main pole fabricated by ion beam milling. Y. Ohsawa^{1,2}, K. Yamakawa² and H. Muraoka². *1. CR&D center, Toshiba Corp., Kawasaki, Japan; 2. RIEC, Tohoku Univ., Sendai, Japan*

3:45

HB-05. Thin film processing realities for Tbit/in² recording. R. Fontana¹, N. Robertson¹ and S. Hetzler². *1. Hitachi GST, San Jose, CA; 2., IBM Research Division, San Jose, CA*

4:00

HB-06. Exchange Coupling in Synthetic Antiferromagnetic Multilayers for Write Head. Y. Xu¹, H. Jiang², K. Sin², Y. Chen² and J. Wang¹. *1. Dept. of Electrical and Computer Engineering, University of Minnesota, Minneapolis, MN; 2. Western Digital Corporation, Fremont, CA*

4:15

HB-07. Laminated high moment FeCo films for perpendicular magnetic recording. *B. Ocker*¹, K. Schuller¹, J. Wrona¹, J. Langer¹ and W. Maass¹ *1. Singulus Nano Deposition Technologies GmbH, Kahl am Main, Germany*

4:30

HB-08. Comparison of Electrical and Magnetic Flux Rise Times in Tape Heads Using Impedance Measurements and High Speed Kerr Magnetometry. A. Kaya^{1,3}, J.A. Bain¹, J.P. Nibarger² and K.D. McKinstry² *1. Carnegie Mellon University, Pittsburgh, PA; 2. Sun Microsystems, Louisville, CO; 3. Hitachi Global Storage, San Jose, CA*

4:45

HB-09. Crosstalk between write transducers. P. Herget¹ and R.G. Biskeborn¹ *1. IBM Corporation, San Jose, CA*

THURSDAY
AFTERNOON
2:30

ROMA

Session HC MAGNETIZATION DYNAMICS

Bob Stamps, Chair

2:30

HC-01. Dynamic interaction between vortices, antivortices and holes in domain walls investigated by means of time resolved Photoemission Electron Microscopy (PEEM). *(Invited)* K. Kuepper¹, S. Wintz¹, M. Buess², J. Raabe², C. Quitmann² and J. Fassbender¹ *1. Ion Beam Physics and Materials Research, FZ Dresden-Rossendorf e. V., Dresden, Germany; 2. Swiss Light Source, Paul Scherrer Institut, Villigen, Switzerland*

3:00

HC-02. Current-induced resonant motion of the magnetic vortex core in a ferromagnetic circular disk. *(Invited)* S. Kasai¹, F. Peter², M. Im², K. Yamada¹, Y. Nakatani³, K. Kobayashi¹, H. Kohn⁴ and T. Ono¹ *1. Institute for Chemical Research, Kyoto University, Uji, Kyoto, Japan; 2. Center for X-Ray Optics, Lawrence Berkeley National Lab, Berkeley, CA; 3. Department of Computer Science, University of Electro-communications, Chofu, Tokyo, Japan; 4. Graduate School of Engineering Science, Osaka University, Toyonaka, Osaka, Japan*

3:30

HC-03. Elementary Eigenmodes of Magnetic Vortex Gyrotropic Motions in Magnetic Nanoelements. K. Lee¹, S. Kim¹, D. Jung¹, Y. Yu¹ and Y. Choi¹ *1. Research Center for Spin Dynamics and Spin-Wave Devices & Nanospintronics Laboratory, Seoul National University, Seoul, South Korea*

3:45

HC-04. Unidirectional switching of the vortex core polarization by excitation with rotating magnetic fields. H. Stoll¹, B. Van Waeyenberge^{1,2}, K. Chou¹, M. Curcic¹, M. Weigand¹, V. Sackmann¹, A. Puzic¹, A. Vansteenkiste², T. Tyliczszak³, G. Woltersdorf⁴, C.H. Back⁴ and G. Schuetz¹ *1. Max Planck Institute for Metals Research, Stuttgart, Germany; 2. Department of Subatomic and Radiation Physics, Ghent University, Gent, Belgium; 3. Advanced Light Source, LBNL, Berkeley, CA; 4. Department of Physics, University of Regensburg, Regensburg, Germany*

4:00

HC-05. Spin-dynamics and mode structure in lithographically patterned Permalloy nanostructures. J.M. Shaw¹, M. Schneider^{1,2}, T. Silva¹, R. McMichael³, S. Kim¹, W. Johnson¹ and P. Kabos¹ *1. National Institute of Standards and Technology, Boulder, CO; 2. University of Montana, Missoula, MT; 3. National Institute of Standards and Technology, Gaithersburg, MD*

4:15

HC-06. Microwave-assisted switching and demagnetizing of NiFe thin films patterned in micro-elements : a domain structure study by Kerr effect. M. Laval¹, J. Bonnefois¹, J. Bobo¹, F. Issac² and F. Boust² *1. LNMH, CNRS ONERA, Toulouse, France; 2. DEMR, ONERA, Toulouse, France*

4:30

HC-07. Modeling of microwave-assisted switching in micron-size magnetic ellipsoids. R. Yanes¹, O. Chubykalo-Fesenko¹, P. Martin Pimentel², B. Leven², B. Hillebrands², V. Tyberkevich³ and A. Slavin³ *1. POMT, Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain; 2. Technische Universitaet Kaiserslautern, Kaiserslautern, Germany; 3. Department of Physics, Oakland University, Rochester, MI*

4:45

HC-08. Nonlinear processes during switching of a thin Permalloy film in different geometries. K. Livesey¹, H. Nembach², M. Kostylev¹, P. Martin-Pimentel², S. Hermsdoerfer², B. Leven², R. Stamps¹ and B. Hillebrands² *1. School of Physics, University of Western Australia, Crawley, WA, Australia; 2. Fachbereich Physik und Forschungsschwerpunkt MINAS, Technische Universitaet Kaiserslautern, Kaiserslautern, Germany*

5:00

HC-09. Precessional magnetization reversal in composite patterned media: Dependence on applied field parameters. *B. Livshitz¹, H.N. Bertram^{2,3}, A. Inomata⁴ and V. Lomakin¹* *1. Department of Electrical and Computer Engineering, UCSD, San Diego, CA; 2. Center for Magnetic Recording Research, UCSD, San Diego, CA; 3. Research Center, Hitachi Global Storage, San Jose, CA; 4. Storage and Intelligent Systems Laboratories, Fujitsu Laboratories Ltd, Atsugi, Japan*

5:15

HC-10. Dynamics of bubble domains in nanodots with high anisotropy. *C. Moutafis¹, S. Komineas², C.F. Vaz³, J.C. Bland¹, T. Shima⁴, T. Seki⁵ and K. Takanashi⁵* *1. Cavendish Laboratory, Cambridge University, Cambridge, United Kingdom; 2. Max-Planck Institute for the Physics of Complex Systems, Dresden, Germany; 3. Applied Physics, Yale University, New Haven, CT; 4. Faculty of Engineering, Tohoku-Gakuin University, Tagajyo, Japan; 5. Institute for Materials Research, Tohoku University, Sendai, Japan*

THURSDAY
AFTERNOON
2:30

PARIS

Session HD
MICROMAGNETICS II
Massimiliano d'Aquino, Chair

2:30

HD-01. Control of domain wall motion in Permalloy nanowires using magnetostatic interactions. *S. Basu¹, D. Allwood¹ and T. Schrefl¹* *1. Department of Engineering Materials, University of Sheffield, Sheffield, United Kingdom*

2:45

HD-02. Domain wall depinning from a notch under oscillating currents: the role of non-adiabaticity. *E. Martinez¹, L. Lopez-Diaz², O. Alejos³ and L. Torres²* *1. Ingenieria Electromecanica, University of Burgos, Burgos, Spain; 2. Fisica Aplicada, University of Salamanca, Salamanca, Spain; 3. Electricidad y Electronica, University of Valladolid, Valladolid, Spain*

3:00

HD-03. Spin-Polarized Current Induced Switching of Composite Free Layers. *C. Yen¹, W. Chen¹, Y. Chen¹, D. Wang¹, C. Shen¹, S. Yang¹, C. Tsai¹, Y. Lee¹, C. Hung¹, K. Shen¹ and M. Kao¹* *1. Electronics and Optoelectronics Research Laboratories (EOL), Industrial Technology Research Institute (ITRI), Hsinchu, Taiwan*

3:15

HD-04. Switching of vortex chirality in $\text{Ni}_{80}\text{Fe}_{20}/\text{Cu}/\text{Co}$ nanopillars by a spin-polarized current pulse. *B.C. Choi¹, Y.K. Hong², J. Rudge¹, E. Girgis¹, J. Kolthammer¹, A. Lyle² and G.W. Donohoe³* *1. Department of Physics & Astronomy, University of Victoria, Victoria, BC, Canada; 2. Department of Electrical and Computer Engineering, University of Alabama, Tuscaloosa, AL; 3. Department of Electrical and Computer Engineering, University of Idaho, Moscow, ID*

HD-05. WITHDRAWN

3:30

HD-06. Temperature dependent exchange stiffness in FePt. *D. Hinzke¹, R.F. Evans¹, U. Nowak¹, R.W. Chantrell¹, U. Atxitia², O. Chubykalo-Fesenko², P. Asselin³ and O.N. Mryasov³* *1. Physics, University of York, York, United Kingdom; 2. Instituto de Ciencia de Materiales de Madrid, Madrid, Spain; 3. Seagate Research, 1251 Waterfront Place, Pittsburgh, PA*

3:45

HD-07. An alternative finite element scheme for dynamic micromagnetic computations. *A. Manzin¹, O. Bottauscio¹ and M. Chiampi²* *1. Istituto Nazionale di Ricerca Metrologica, Torino, Italy; 2. Ingegneria Elettrica, Politecnico di Torino, Torino, Italy*

4:00

HD-08. Innovative weak formulation for the Landau-Lifschitz-Gilbert equation. *H. Szabolcs^{1,2}, J. Toussaint^{1,2}, L.D. Buda-Prejbeanu^{2,3}, F. Alouges⁴, E. Kitisikis^{2,3} and O. Fruchart¹* *1. Department of Nanosciences, Institut Neel, CNRS, Grenoble cedex 9, France; 2. Institut National Polytechnique de Grenoble, Grenoble, France; 3. Laboratoire SPINTEC, CEA, Grenoble, France; 4. Laboratoire de Mathématique, Université Paris XI, Orsay, France*

4:15

HD-09. Stochastic dynamics and optimal switching paths in thermally activated magnetization processes of ferromagnetic nanoparticles. *C. Serpico¹, G. Bertotti², C.S. Ragusa³, M. d'Aquino⁴, I.D. Mayergoyz⁵ and P. Ansalone³* *1. Dipartimento di Ingegneria Elettrica, Università di Napoli "Federico II", Napoli, Italy; 2. Istituto Nazionale di Ricerca Metrologica (INRiM), Torino, Italy; 3. Dipartimento di Ingegneria Elettrica, Politecnico di Torino, Torino, Italy; 4. Dipartimento per le Tecnologie, Università di Napoli "Parthenope", Napoli, Italy; 5. ECE Department and UMIACS, University of Maryland, College Park, MD*

4:30

HD-10. A Study of Pseudoelastic Phenomenon in Ferromagnetic Shape Memory Alloy NiMnGa by Phase-field Simulation. *X. Ma¹, P. Wu¹, J. Zhang² and L. Chen²* *1. Department of Physics, University of Science and Technology Beijing, Beijing, China; 2. Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA*

4:45

HD-11. Effects of nanowire roughness on spin wave propagation. *S. Bance*¹, T. Schrefl¹, D. Allwood¹, G. Hrkac¹ and A. Goncharov¹ *1. University of Sheffield, Sheffield, United Kingdom*

5:00

HD-12. Effect of interface exchange coupling on the reversal of single antiferromagnetic grains in exchange bias systems. *J. Jackson*¹, U. Nowak¹ and R. Chantrell¹ *1. Physics, University of York, York, United Kingdom*

THURSDAY
AFTERNOON
2:30

LONDRES

Session HE PERMANENT MAGNET MATERIALS

George Hadjipanayis, Chair

2:30

HE-01. Microtexture and Magnetic Microstructure of Sputtered NdFeB Thick Films Destined for Application in Micro-Electro-Mechanical Systems (MEMS). *T.G. Woodcock*¹, K. Khlopkov¹, A. Walther², N.M. Dempsey², D. Givord² and O. Gutfleisch¹ *1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany; 2. Institut Néel, CNRS, Grenoble, France*

2:45

HE-02. Temperature dependent anisotropy in epitaxial Pr-Co films. *A.K. Patra*¹, M. Eisterer², R. Biele^{1,3}, S. Fähler¹, L. Schultz¹ and V. Neu¹ *1. IFW Dresden, Dresden, Germany; 2. Atomic Institute of the Austrian Universities, Vienna, Austria; 3. University of Technology Dresden, Dresden, Germany*

3:00

HE-03. Sintered Sm₂Co₁₇-based Magnets with Small Additions of Indium. *A. Gabay*¹, M. Marinescu², J. Liu² and G.C. Hadjipanayis¹ *1. University of Delaware, Newark, DE; 2. Electron Energy Corporation, Landisville, PA*

3:15

HE-04. Prediction of temperature demagnetization of bonded rare earth magnets by finite element analysis. *T. Schliesch*¹ and T. Lindner¹ *1. Max Baermann GmbH, Bergisch Gladbach, Germany*

3:30

HE-05. New Dy-substituted Ba hexaferrites with high coercivity. *G. Litsardakis*¹, I. Manolakis¹, A. Stergiou², C. Serletis² and K.G. Efthimiadis² *1. Dept. of Electrical & Computer Engineering, Aristotle University, Thessaloniki, Greece; 2. Dept. of Physics, Aristotle University, Thessaloniki, Greece*

3:45

HE-06. Strain-induced exchange bias effects in chemically ordered Pt₃Fe single crystal. *S. Kobayashi*¹, S. Takahashi¹, Y. Kamada¹ and H. Kikuchi¹ *1. Faculty of Engineering, Iwate University, Morioka, Japan*

4:00

HE-07. Fe-Pt thick film magnets prepared by high-speed PLD method. *S. Shibata*¹, *M. Nakano*¹, T. Yanai¹ and H. Fukunaga¹ *1. Electronics and Electrical Engineering, Nagasaki University, Nagasaki, Japan*

4:15

HE-08. Coercivity generation of surface Nd₂Fe₁₄B grains and mechanism of fcc-phase formation at Nd/Nd₂Fe₁₄B interface in Nd-sputtered Nd-Fe-B sintered magnets. *T. Fukagawa*¹ and S. Hirosawa¹ *1. Magnetic Materials Research Laboratory NEOMAX Company, Hitachi Metals, Ltd., 2-15-17, Egawa, Shimamoto-cho, Mishima-gun, Osaka, Japan*

4:30

HE-09. Wettability and interfacial microstructure between Nd₂Fe₁₄B and Nd-rich phases in Nd-Fe-B alloys. *R. Goto*¹, S. Nishio¹, M. Matsuura¹, N. Tezuka¹ and S. Sugimoto¹ *1. Department of Materials Science, Tohoku University, Sendai, Japan*

4:45

HE-10. The role of Cu addition in the coercivity enhancement of sintered Nd-Fe-B magnets. *T. Ohkubo*^{1,2}, W. Li¹, K. Hono^{1,2}, T. Akiya³ and H. Kato³ *1. National Institute for Materials Science, Tsukuba, Japan; 2. CREST, JST, Japan; 3. Tohoku University, Sendai, Japan*

5:00

HE-11. Magnetic Properties of Sm₂Co₁₇ & Sm₂Co₇ Sputtered and Post-annealed Thin Films. Effect of Mo Underlayer. *I. Lucas*¹, M. Maicas², L. Pérez³ and M. Díaz - Michelena¹ *1. Dto: Space Programs and Space Sciences, I.N.T.A., 28850 Torrejón de Ardoz, Madrid, Spain; 2. (ISOM) ETSI Telecomunicación, Universidad Politécnica de Madrid (UPM), Madrid, Madrid, Spain; 3. Dto:Física de Materiales, Universidad Complutense de Madrid (UCM), Madrid, Madrid, Spain*

5:15

3:30

HE-12. Preparation and magnetic study of the CoFe₂O₄-CoFe₂ nanocomposite powders. F. Cabral^{1,2}, F. Machado¹, J. Araújo², J. Soares³, A. Rodrigues¹ and A. Araújo². *1. Departamento de Física, Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil; 2. Departamento de Física Teórica e Experimental, Univesidade Federal do Rio Grande do Norte, Natal, Rio Grande do Norte, Brazil; 3. Departamento de Física, Univesidade do Estado do Rio Grande do Norte, Mossoró, Rio Grande do Norte, Brazil*

HF-04. Water based colloids of Fe₃O₄/SiO₂ magnetic nanoparticles with core/shell structure for magnetic hyperthermia. M.A. Gonzalez-Fernandez¹, T. Torres², M.A. Verges³, G.F. Goya², C.J. Serna¹ and M.P. Morales¹. *1. Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain; 2. Institute of Nanoscience of Aragon (INA), University of Zaragoza, Zaragoza, Spain; 3. Department of Organic and Inorganic Chemistry, Universidad de Extremadura, Badajoz, Spain*

3:45

THURSDAY
AFTERNOON
2:30

BERLIN

Session HF LIFE SCIENCE AND APPLICATIONS-III

Ricardo Ibarra, Chair

2:30

HF-01. Bimodal use of maghemite nanoparticles as contrast agents for magnetic resonance imaging (T1 and T2 CA's) through modulation of their stabilizing coating. (Invited) E. Taboada¹, A. Roig¹, E. Rodriguez² and M. Delville³. *1. Institut de Ciència de Materials de Barcelona, ICMAB-CSIC, Bellaterra, Spain; 2. Center for Molecular Imaging Research, MGH-Harvard Medical Hospital, Boston, MA; 3. Institut de Chimie de la Matière Condensée de Bordeaux, ICMCB-CNRS, Bordeaux, France*

HF-05. Antiferromagnetic susceptibility in ferritin. N.J. Silva¹, A. Urtizberea¹, A. Millán¹, F. Palacio¹, E. Kampert², U. Zeitler², H. Rakoto³ and V.S. Amaral⁴. *1. Física de la Materia Condensada, Instituto de Ciencia de Materiales de Aragón CSIC/Universidad de Zaragoza, Zaragoza, Spain; 2. Radboud Univ. Nijmegen, High Field Magnet Lab, Nijmegen, Netherlands; 3. LNCMP, Toulouse, France; 4. Departamento de Física and CICECO, Universidade de Aveiro, Aveiro, Portugal*

4:00

HF-06. Iron oxide *versus* Fe₅₅Pt₄₅@Fe₂O₃ ferromagnetic nanoparticles: improved magnetic properties of core/shell nanostructure for biomedical applications. L.C. Varanda¹, F.J. Santos², I. Momotaro³ and M. Jafelicci Jr.². *1. Físico-Química, Instituto de Química de São Carlos - USP, São Carlos, São Paulo, Brazil; 2. Físico-Química, Instituto de Química de Araraquara - UNESP, Araraquara, São Paulo, Brazil; 3. Física, Faculdade de Ciências - UNESP, Bauru, São Paulo, Brazil*

4:15

HF-07. Surface modified superparamagnetic nanoparticles as a novel magnetic carrier. M. Lin¹, S. Li², J. Gu¹, H. Lee³, M. Mamoun² and D. Kim¹. *1. Institute of Science and Technology in Medicine, Keele University, Stoke-on-Trent, United Kingdom; 2. Materials Chemistry Divisions, Royal Institute of Technology, Stockholm, Sweden; 3. Department of Materials Science and Engineering, Myongji University, Kyunggi-do, South Korea*

4:30

HF-02. Magnetic Hyperthermia with Fe₃O₄ nanoparticles: the Influence of Particle Size and Domain Structure on Energy Absorption. G.F. Goya¹, E. Lima Jr.², A.D. Arelaro², T. Torres¹, H.R. Rechenberg², L. Rossi³, C. Marquina^{4,1} and M.R. Ibarra^{1,4}. *1. Nanoscience Institute of Aragon, University of Zaragoza, Zaragoza, Zaragoza, Spain; 2. Physics Institute, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil; 3. Chemistry Institute, University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil; 4. Instituto de Ciencia de Materiales de Aragón-CSIC, University of Zaragoza, Zaragoza, Zaragoza, Spain*

3:15

HF-03. Synthesis and Cellular Uptake of Folate-Conjugated Hydrophobic Superparamagnetic Iron Oxide Nanoparticles. K. Woo¹, J. Moon^{1,2}, K. Choi³, K. Yoon³ and T. Seong¹. *1. Nano-Materials Research Center, KIST, Seoul, South Korea; 2. Department of Materials Science and Engineering, Korea University, Seoul, South Korea; 3. Institute for Radiological Imaging Science, Wonkwang University School of Medicine, Iksan, South Korea*

4:45

HF-09. Hysteresis power loss heating of ferromagnetic nano-particles designed for magnetic thermoablation. E. Kita¹, H. Yanagihara¹, S. Hashimoto², K. Yamada², T. Oda², M. Kishimoto³ and A. Tasaki¹. *1. Institute of Applied Physics, University of Tsukuba, Tsukuba, Ibaraki, Japan; 2. Institute of Clinical Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan; 3. Hitachi Maxell, Ltd., Oyamazaki, Kyoto, Japan*

THURSDAY
AFTERNOON
2:30

AMSTERDAM

4:00

Session HG
MAGNETOELASTIC MATERIALS AND DEVICES

Mike Gibbs, Chair

2:30

HG-01. The local atomic Joule magnetostriction of $\text{Fe}_{81}\text{Ga}_{19}$ *M.P. Ruffoni¹, S. Pascarelli¹, R. Grössinger², R. Sato-Turtelli² and R.F. Pettifer³* *1. European Synchrotron Radiation Facility, Grenoble, France; 2. Technical University of Vienna, Vienna, Austria; 3. Department of Physics, University of Warwick, Coventry, United Kingdom*

2:45

HG-02. The Effect of Tempering on the Magnetostriction of Fe-Ga Alloys. *T.A. Lograsso^{1,2} and M. Huang¹* *1. Institute for Physical Research and Technology, Iowa State University, Ames, IA; 2. Materials and Engineering Physics, Ames Laboratory, Ames, IA*

3:00

HG-03. Magnetic field and stress dependence of FeGa 3-D shaped polycrystalline magnetostrictive materials properties. *N. Lupu¹ and H. Chiriac¹* *1. Magnetic Materials and Devices, National Institute of Research and Development for Technical Physics, Iasi, Romania*

3:15

HG-04. Magnetostriction of Fe-X (X = B, Al, Ga, Si, Ge) intermetallic alloys. *G. Roland¹, S. Reiko¹ and M. Nasir¹* *1. Inst. of Solid State Physics, Techn. Univ. Vienna, Vienna, Austria*

3:30

HG-05. Magnetic and magnetoelastic properties of electrodeposited FeGa/CoFeB multilayered films and nanowires arrays. *N. Lupu¹, P. Pascariu¹, C. Gherasim¹ and H. Chiriac¹* *1. Magnetic Materials and Devices, National Institute of Research and Development for Technical Physics, Iasi, Romania*

3:45

HG-06. Modelling and experimental analysis of magnetostrictive devices: from the material characterisation to their dynamic behaviour. *O. Bottauscio¹, R. Bonin¹, A. Lovisolo¹, P. Roccato², C. Sasso¹ and M. Zucca¹* *1. Electromagnetics, Istituto Nazionale di Ricerca Metrologica, Torino, Italy; 2. Dip. Ingegneria Elettrica, Politecnico di Torino, Torino, Italy*

HG-07. Design of a multipurpose magnetostrictive device. *O. Bottauscio¹, A. Lovisolo¹, P. Roccato² and M. Zucca¹* *1. Electromagnetics, INRIM, Torino, Italy; 2. Dip. Ing. Elettrica, Politecnico di Torino, Torino, Italy*

4:15

HG-08. Temperature dependence of magnetostriction of $\text{Co}_{1+x}\text{Ge}_x\text{Fe}_{2-2x}\text{O}_4$ for magnetostrictive sensor and actuator applications. *N. Ramvah¹, I.C. Nlebedim¹, S.H. Song², Y. Melikhov¹, J.E. Snyder¹, D.C. Jiles¹, A.J. Moses¹ and P.I. Williams¹* *1. Wolfson Centre for Magnetics, Cardiff University, Cardiff, Wales, United Kingdom; 2. Materials Science and Engineering Department, Iowa State University, Ames, IA*

4:30

HG-09. Magnetostriction studies on antiferromagnetic $\text{Mn}_x\text{Fe}_{100-x}$ ($30 \leq x \leq 55$) alloys. *M. Yan¹, T. Ma¹, J. Zhang¹ and Y. Xu¹* *1. Department of Materials Science and Engineering, Zhejiang University, Hangzhou, China*

4:45

HG-10. Magnetic softening of magnetostrictive $(\text{Fe}_{80}\text{Co}_{20})_{1-95}\text{B}_{20}$ amorphous thin films with a thickness modulation of the magnetic anisotropy. *J. Prieto², M. González-Guerrero¹, D. Ciudad¹, P. Sánchez¹ and C. Aroca¹* *1. Física Aplicada, ETSI Telecomunicación UPM, Madrid, Madrid, Spain; 2. ISOM, Universidad Politécnica de Madrid, Madrid, Madrid, Spain*

5:00

HG-11. Fine structure observation near critical temperature in $\text{Gd}_5\text{Si}_{1.95}\text{Ge}_{2.05}$ *R.L. Hadimani¹, Y. Melikhov¹, J.E. Snyder¹ and D.C. Jiles¹* *1. Wolfson Centre for Magnetics, Cardiff University, Cardiff, Wales, United Kingdom*

5:15

HG-12. On the nature of the Griffiths-like phase behaviour in Gd_5Ge_4 giant magnetocaloric alloy. *N. Pérez^{1,2}, F. Casanova^{2,3}, F. Bartolomé^{4,5}, L.M. García^{4,5}, S. DeBrion⁶, A. Labarta^{1,2} and X. Batlle^{1,2}* *1. Física Fonamental, Universitat de Barcelona, Barcelona, Catalonia, Spain; 2. Institut de Nanociència i Nanotecnologia IN2UB, Universitat de Barcelona, Barcelona, Catalonia, Spain; 3. Physics Department, University of California (UCSD), San Diego, CA; 4. Instituto de Ciencia de Materiales de Aragón, CSIC, Zaragoza, Aragón, Spain; 5. Física de la Materia Condensada, Universidad de Zaragoza, Zaragoza, Aragón, Spain; 6. Institut Néel, CNRS-UJF, Grenoble, France*

THURSDAY
AFTERNOON
2:30

CARACAS

3:45

Session HH
CURRENT INDUCED DW MOTION

Joo-Von Kim, Chair

2:30

HH-01. Spin Dynamics and Gilbert damping of a nanomagnet connected to leads. *A. Núñez¹ and R. Duine² 1. Departamento de Física, Facultad de Ciencias Físicas y Matemáticas, Universidad de Chile, Santiago, Chile; 2. Institute for Theoretical Physics, Utrecht University, Utrecht, Netherlands*

2:45

HH-02. Race track memories seen from an ab-initio point of view. *P. Weinberger^{1,2} 1. Center for Computational Nanoscience, Vienna, Austria; 2. Department of Physics, New York University, New York, NY*

3:00

HH-03. DETECTION OF CURRENT-INDUCED OSCILLATIONS OF PINNED DOMAIN WALLS. *M. Kläuit¹, D. Bedau¹, S. Krzyk¹, G. Faini², L. Vila² and U. Rüdiger¹ 1. Physics, University of Konstanz, Konstanz, Germany; 2. LPN-CNRS, Marcoussis, France*

3:15

HH-04. Current-induced switching of the magnetic vortex core in a ferromagnetic circular dot. *K. Yamada¹, S. Kasai¹, Y. Nakatani², K. Kobayashi¹, H. Kohn³, A. Thiaville⁴ and T. Ono¹ 1. Institute for Chemical Research, Kyoto University, Uji, Kyoto, Japan; 2. Department of Computer Science, University of Electro-Communications, Chofu, Tokyo, Japan; 3. Graduate School of Engineering Science, Osaka University, Toyonaka, Osaka, Japan; 4. Laboratoire de Physique des Solides, CNRS and Univ. Paris-Sud, Orsay, France*

3:30

HH-05. Magnetization reversal control using a current pulse in Permalloy nanowires. *Y. Togawa¹, T. Kimura^{1,2}, K. Harada^{1,3}, T. Akashi⁴, T. Matsuda^{1,3}, A. Tonomura^{1,3} and Y. Otani^{1,2} 1. Frontier Research System, Institute of Physical and Chemical Research (RIKEN), Wako, Saitama, Japan; 2. Institute for Solid State Physics, University of Tokyo, Kashiwa, Chiba, Japan; 3. Advanced Research Laboratory, Hitachi, Ltd., Hatoyama, Saitama, Japan; 4. Hitachi High-Technologies Co., Hitachinaka, Ibaraki, Japan*

HH-06. Stochastic magnetic field driven domain wall motion in a spin-valve nanowire. *X. Jiang¹, L. Thomas¹, R. Moriya¹, M. Hayashi¹, B. Bergman¹, C. Rettner¹ and S. Parkin¹ 1. IBM Almaden Research Center, San Jose, CA*

4:00

HH-07. Stochastic domain wall motion under a polarized current in wires with perpendicularly magnetized layers. *C. Burrowes¹, D. Ravelosona¹, D. Stancu¹, N. Vernier¹, C. Chappert¹, B. Terris², J. Katine² and E. Fullerton³ 1. Institut d'Electronique Fondamentale, Orsay, France; 2. HitachiGST, San Jose, CA; 3. UC San Diego, San Diego, CA*

4:15

HH-08. Effect of anisotropy distribution on domain wall motion in nanowires with perpendicular anisotropy. *Y. Nakatani¹ and T. Ono² 1. Department of Computer Science, University of Electro-Communications, Tokyo, Japan; 2. Kyoto University, Uji, Japan*

4:30

HH-09. Current-driven domain wall motion, nucleation, and propagation in a Co/Pt multi-layer strip with a stepped structure. *T. Suzuki¹, S. Fukami¹, K. Nagahara¹, N. Oshima¹ and N. Ishiwata¹ 1. Device Platforms Res. Labs., NEC, Sagamihara, Kanagawa, Japan*

4:45

HH-10. Current-Driven Domain Wall Motion in CoCrPt Wires with Perpendicular Magnetic Anisotropy. *H. Tanigawa¹, K. Kondou¹, T. Koyama¹, K. Nakano¹, S. Kasai¹, N. Ohshima², S. Fukami², N. Ishiwata² and T. Ono¹ 1. Institute for Chemical Research, Kyoto University, Uji, Japan; 2. Device Platforms Research Laboratories, NEC Corporation, Sagamihara, Japan*

5:00

HH-11. Intrinsic threshold current density of domain wall motion in nano-strips with perpendicular magnetic anisotropy for use in low-write-current MRAMs. *S. Fukami¹, T. Suzuki¹, N. Ohshima¹, K. Nagahara¹ and N. Ishiwata¹ 1. Device Platforms Research Laboratories, NEC Corporation, Sagamihara, Japan*

5:15

HH-12. Current domain wall dragging in GaMnAs. *N. VERNIER^{1,3}, L. Thevenard², A. Lemaitre², A. Miard², G. Faini², L. Vila², J. Ferré³ and J. Adam³ 1. IEF, Université Paris-Sud, Orsay, France; 2. LPN, CNRS, Marcoussis, France; 3. LPS, Université Paris-sud, Orsay, France*

THURSDAY
AFTERNOON
2:30

POLIVALENTE

Session HL
RECORDING SYSTEMS AND SERVO II
(POSTER SESSION)

Mark Bedillion, Chair

HL-01. Aerodynamic damping on vibration of rotating disks and effects of shroud and top cover. *T. Eguchi¹ 1. Central Research Laboratory, Hitachi, Ltd., Fujisawa, Ibaraki, Japan*

HL-02. Adaptive frequency identification method for multiple unknown disturbances in HDDs. *Q. Jia¹ and Z. Wang² 1. Storage Mechanics Lab, Hitachi Asia Ltd, Singapore, Singapore; 2. School of Electrical Engineering and Computer Science, Oregon State University, Corvallis, OR*

HL-03. A disturbance observer design for SPM-based data storage system. *J. Moon¹, C. Chung¹, C. Lee¹ and Y. Kim² 1. Electrical Engineering, Hanyang University, Seoul, South Korea; 2. Devices & Materials Lab., LG Elite, Seoul, South Korea*

HL-04. A discrete-time modified sliding mode proximate time optimal servomechanism for SPM-based data storage systems. *J. Jeong¹, C. Lee¹, C. Chung¹ and Y. Kim² 1. Electrical Engineering, Hanyang University, Seoul, South Korea; 2. Devices & Materials Lab., LG Elite, Seoul, South Korea*

HL-05. Magnetic recording performance of 'Bit Printing method' on PMR media and its extendability to the higher areal density. *A. Morooka¹, M. Nagao¹, T. Yasunaga¹ and K. Nishimaki² 1. Recording Media Research Laboratories, FUJI FILM co.,LTD., Odawara, Japan; 2. Production Engineering & Development Center, FUJI FILM co.,LTD., Odawara, Japan*

HL-06. Using steady solutions of Reynolds-Averaged Navier Stokes (RANS) equations to estimate flow induced vibrations (FIV) of hard disk drive carriage arms. *T. Yip¹, E. Ong¹, A. Yudhanto¹, Z. He¹ and Q. Zhang¹ 1. Data Storage Institute, Singapore, Singapore*

HL-07. A Novel Settling Controller for Dual-stage Servo Systems. *J. Zhang¹, C. Du¹ and S. Ge² 1. Data Storage Institute, Singapore, Singapore; 2. Department of Electrical & Computer Engineering, National University of Singapore, Singapore, Singapore*

HL-08. PES Generation and Evaluation for Bit Patterned Servo. *S. Zhang¹ and W. Wong¹ 1. Data Storage Institute, Singapore, Singapore*

THURSDAY
AFTERNOON
2:30

POLIVALENTE

Session HM
RECORDING SYSTEMS, CODING AND CHANNELS - I
(POSTER SESSION)

Roger Wood, Chair

HM-01. Mean-Adjusted PDNP Detector for Perpendicular Recording Channels With NLTS. *Z. Wu¹, P.H. Siegel¹, J.K. Wolf¹ and N. Bertram^{1,2} 1. Center for Magnetic Recording Research, University of California, San Diego, La Jolla, CA; 2. Hitachi Global Storage Technologies, San Jose, CA*

HM-02. Ordered statistics soft decoding of Reed-Solomon codes over intersymbol interference channels. *F.Y. Lim¹, A. Kav̇ci¹ and M. Fossorier¹ 1. University of Hawaii, Manoa, Honolulu, HI*

HM-03. Enhanced Message Passing in Turbo Product Code. *N. Yeh¹, P. Steiner¹ and Y. Li^{1,2} 1. Seagate Technology, Fremont, CA; 2. Presently with AMD, Yardley, PA*

HM-04. A New Burst Detection Method Using Parity Check Matrix of LDPC Code for Bit Flipping Burst-like Signal Degradation. *Y. Nakamura¹, M. Nishimura¹, Y. Okamoto¹, H. Osawa¹ and H. Muraoka² 1. Graduate School of Science and Engineering, Ehime University, Matsuyama, Japan; 2. RIEC, Tohoku University, Sendai, Japan*

HM-05. Low-Complexity LDPC Decoder Architecture for High-Speed Magnetic Recording. *C. Zhang^{1,2}, Z. Wang³, L. Li^{1,2}, J. Lin^{1,2} and M. Gao^{1,2} 1. Institute of VLSI Design, Physics Department, Nanjing University, Nanjing, Jiangsu, China; 2. Key Laboratory of Advanced Photonic and Electronic Materials, Nanjing University, Nanjing, Jiangsu, China; 3. School of Electrical Engineering and Computer Science, Oregon State University, Corvallis, OR*

HM-06. Message-Passing Detector with Serial Concatenated Codes for PMR Channel. *D. Park¹, J. Lee¹ and J. Lee² 1. School of Electronic Engineering, Soongsil University, Seoul, South Korea; 2. Storage System Division, Samsung Electronics, Suwon, South Korea*

HM-07. Hardware-Efficient LDPC Decoding for Magnetic Recording. *Z. Cui¹, Z. Wang¹, X. Zhang² and Q. Jia³ 1. Oregon State University, Corvallis, OR; 2. Case Western Reserve University, Cleveland, OH; 3. Hitachi Asia Ltd, Singapore, Singapore*

HM-08. Perpendicular Magnetic Recording Channel Equalization Based on Gaussian Sum Approximation. *S. Choi¹, G. Kong¹, H. Cho¹, D. Lee¹, J. Lee³ and J. Lee² 1. School of Electrical and Electronic Engineering, Yonsei University, Seoul, South Korea; 2. School of Electronic Engineering, Soongsil University, Seoul, South Korea; 3. Storage System Division, Samsung Electronics, Suwon, South Korea*

HM-09. Simplified Neural Network Equalizer with Noise Whitening Function for GPRML System. *H. Osawa¹, M. Hino¹, N. Shinohara¹, Y. Okamoto¹, Y. Nakamura¹ and H. Muraoka² 1. Graduate School of Science and Engineering, Ehime University, Matsuyama, Japan; 2. RIEC, Tohoku University, Sendai, Japan*

HM-10. Digital Storage Channel Equalization Using A Bilinear Recursive Polynomial System. *S. Choi¹, H. Cho¹, G. Kong¹, J. Lee³ and J. Lee² 1. School of Electrical and Electronic Engineering, Yonsei University, Seoul, South Korea; 2. School of Electronic Engineering, Soongsil University, Seoul, South Korea; 3. Storage System Division, Samsung Electronics, Suwon, South Korea*

HM-11. Interleaved Modified Array Codes (IMAC) Hardware Design and Performance for High-Rate Perpendicular Magnetic Recording Systems. *P. Leekul^{1,3}, W. Singhaudom¹ and P. Supnithi^{1,2} 1. Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand; 2. Data Storage Technology and Applications Research Center (D*STAR), King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand; 3. Research Center for Communications and Information Technology (ReCCIT), King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*

HM-12. Nonbinary LDPC codes for 4K-byte sectors. W. Chang¹ and J. CRUZ¹ *1. The University of Oklahoma, Norman, OK*

**THURSDAY
AFTERNOON
2:30**

POLIVALENTE

Session HN

**MAGNETIC NANOCLUSTERS AND NANOPARTICLES III
(POSTER SESSION)**

Leonard Spinu, Chair

HN-01. Magnetic properties of self-assembled cobalt nanoparticles crystal superlattices. M. Varon¹, L. Peña², L. Balcells², V.F. Puntès¹ and B. Martínez² *1. Institut Català de Nanotecnologia, Bellaterra, Barcelona, Spain; 2. Magnetic Materials, ICMAB-CSIC, Bellaterra, Barcelona, Spain*

HN-02. One-Dimensional Hierarchical Nanostructure Generated by Coating SiOX Nanowires with L10 CoPt Nanoparticles. J. Kim¹, J. Kim¹, J. Park¹, K. Baek¹, H. Woo¹, S. Kim¹, C. Kim¹ and C. Yoon¹ *1. Materials Science and Engineering, Hanyang University, Seoul, South Korea*

HN-03. Effects of oxidation and particle size on saturation magnetization of iron nanoparticles. H. Matsuura¹, K. Seto², K. Kawano¹, M. Takahashi³ and T. Ogawa⁴ *1. TAIYO YUDEN Co., Ltd., Takasaki-shi, Japan; 2. Dept. of Elec. Eng., Tohoku Univ., Sendai, Japan; 3. NICHe, Tohoku Univ., Sendai, Japan; 4. CRESS, Tohoku Univ., Sendai, Japan*

HN-04. Phase transition of the escape rate for ferromagnetic nanoparticles: A magnetic quantum tunneling study. J. Florez¹ and P. Vargas¹ *1. Phys. Dept. USM, Valparaíso, Chile*

HN-05. Magnetic characterization of nanowire arrays using first order reversal curves. R. Lavín¹, J.C. Denardin¹, J. Escrig¹, D. Altbir¹, A. Cortés² and H. Gómez² *1. Física, USACH, Santiago, Chile; 2. Química, UCV, Valparaíso, Chile*

HN-06. AC susceptibility study of spin dynamics in Fe-doped La_{0.7}Pb_{0.3}Mn_{0.8}Fe_{0.2}O₃ L. Fernandez Barquin¹, J. Gutiérrez², J. Barandiaran², J. Bermejo² and S. Kaul³ *1. CITIMAC, Facultad de Ciencias, Universidad de Cantabria, Santander, Cantabria, Spain; 2. Electricidad y Electrónica, UPV / EHU, Fac. Ciencia y Tecnología, Bilbao, Bizkaia, Spain; 3. School of Physics, University of Hyderabad, Hyderabad, India*

HN-07. Exchange coupling in core(ferromagnet)-shell(antiferromagnet) structured nano-particles. N.N. Phuoc¹, T. Suzuki¹, R.W. Chantrell² and U. Nowak² *1. Information Storage Materials Laboratory, Toyota Technological Institute, Nagoya, Aichi, Japan; 2. Department of Physics, University of York, York, United Kingdom*

HN-08. Single cobalt clusters embedded in isolating matrix. C. Raufast¹, A. Tamion¹, V. Dupuis¹, T. Fournier², T. Crozes², E. Bernstein¹, E. Bonet² and W. Wernsdorfer² *1. Laboratoire de Physique de la Matière Condensée et Nanostructures, Lyon, France; 2. Institut Néel, CNRS, Grenoble, France*

HN-09. Thermal relaxation phenomena probed by transverse susceptibility measurements performed at different frequencies. J. Calleja¹, C. Radu², L. Spinu², R. Matarranz¹, B. Presa¹ and M. Contreras¹ *1. Física, Universidad de Oviedo, Oviedo, Spain; 2. AMRI, University of new Orleans, New Orleans, LA*

HN-10. Self-ordered growth of ferrite nanopyrramids. F. Rigato¹, B.B. Nelson-Cheeseman², J. Caicedo Roque¹, D. Hrabovský¹, F. Sánchez¹ and J. Fontcuberta¹ *1. Magnetic Materials, ICMAB, Bellaterra, Barcelona, Spain; 2. Materials Science and Engineering, University of California, Berkeley, CA*

HN-11. On the low-temperature dependence of the nanoparticle interactions in the Mn₂Zn_{1-x}Fe₂O₄ system. A. Mendoza¹, O. Marín², D. Reyes³, A. Ovidio¹ and P. Prieto³ *1. Physics Department, Universidad Nacional de Colombia, Bogotá, Colombia; 2. Magnetic Materials and Nanostructures, Universidad del Quindío, Armenia, Colombia; 3. Thin Films Group, Universidad del Valle, Cali, Colombia*

HN-12. Magnetostatic interactions between magnetic nanotubes. J. Escrig¹, S. Allende¹, D. Altbir¹, P. Landeros² and M. Bahiana³ *1. Departamento de Física, Universidad de Santiago de Chile, Santiago, Chile; 2. Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile; 3. Instituto de Física, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil*

HN-13. Magnetic nanowires: from synthesis to permanent magnet applications. G. Viau¹, Y. Soumare², T. Maurer³, J. Piquemal², F. Ott³ and G. Chaboussant³ *1. LPCNO, INSA Toulouse, TOULOUSE, France; 2. ITODYS, Université Paris7, PARIS, France; 3. LLB, CEA Saclay, ORSAY, France*

HN-14. Numerical simulation of magnetic cluster in transition region. H. Endo¹, Y. Uesaka¹, Y. Nakatani², N. Hayashi³ and H. Fukushima⁴ *1. Nihon University, Koriyama, Fukushima, Japan; 2. University of Electro-Communications, Chofu, Japan; 3. Individual capacity, Tokyo, Japan; 4. Individual capacity, Chiba, Japan*

HN-15. Ligand exchange in gold-coated FePt nanoparticles. P. de la Presa¹, T. Rueda¹, M. Morales² and A. Hernando¹ *1. Instituto de Magnetismo Aplicado, UCM, Las Rozas, Madrid, Spain; 2. ICMM-CSIC, Madrid, Madrid, Spain*

HN-16. Magnetic behavior of oleate-capped monodisperse iron oxide nanoparticles prepared in polyol solutions. G. Caruntu^{1,2}, D. Caruntu^{1,2} and C.J. O'Connor^{1,2} *1. Advanced Materials Research Institute, New Orleans, LA; 2. Chemistry Department, University of New Orleans, New Orleans, LA*

HN-17. Interplay Between Magnetic Coupling of Magnetic Nanoparticles and Magnetic/Superconducting Proximity Effect. E. Navarro¹, Y. Huttel², A. Cebollada³, A. Perez-Junquera⁴, M. Velez⁴, J.I. Martin⁴, J.M. Alameda⁴ and J.L. Vicent¹ *1. Física Materiales, Univ. Complutense, Madrid, Spain; 2. Instituto Ciencia de Materiales, CSIC, Madrid, Spain; 3. Instituto Microelectronica de Madrid, CSIC, Madrid, Spain; 4. Física, Universidad de Oviedo, Oviedo, Spain*

Session HO
HEAD-MEDIA INTERFACE AND TRIBOLOGY - III
(POSTER SESSION)
Bernhard Knigge, Chair

HO-01. Lube depletion caused by thermal-desorption in heat assisted magnetic recording. *Y. Ma¹ and B. Liu¹. Data Storage Institute, Singapore, Singapore*

HO-02. Study of slider's flying behavior under by various temperature and humidity conditions. *T. Watanabe¹ and K. Kusakawa¹. Fuji Electric Device Technology Co.,Ltd, Matsumoto, Japan*

HO-03. A novel simulation of air/liquid bearing based on lattice Boltzmann method. *D. Kim¹, M.S. Jhon¹ and H. Kim¹. Depart of Chemical Engineering and Data Storage Systems Center, Carnegie Mellon University, Pittsburgh, PA*

HO-04. Numerical Simulation of Touchdown/Takeoff of Sphere-Pad Slider. *H. Li¹, J. Li², J. Xu², Y. Shimizu², K. Ono² and S. Yoshida¹. Storage Mechanics Laboratory, Hitachi Asia Ltd., Singapore, Singapore; 2. Central Research Laboratory, Hitachi Ltd., Kanagawa, Japan*

HO-05. Dynamically controlled thermal flying-height control slider. *T. Shiramatsu¹, T. Atsumi¹, M. Kurita¹, Y. Shimizu¹ and H. Tanaka². Central Research Laboratory, HITACHI, Ltd, Fujisawa-shi, Kanagawa-ken, Japan; 2. Hitachi Global Storage Technologies Japan, Ltd., Odawara-shi, Kanagawa-ken, Japan*

HO-06. Transient analysis of micro thermal actuator for flying height control. *J. Liu¹, J. Li², H. Li¹, J. Xu² and S. Yoshida¹. Storage Mechanics Laboratory, R&D Center, Hitachi Asia Ltd, Singapore, Singapore; 2. Storage Technology Research Center, Hitachi Ltd, Fujisawa, Japan*

HO-07. Origin of Heater Induced Voltage in Magnetic Recording Heads. *D. Song¹ and M.T. Johnson¹. Seagate Technologies, Bloomington, MN*

HO-08. Signal modulation study of TuMR reader near head/disk contact. *N. Kim¹, Y. Tang¹ and X. Che¹. Samsung Information Systems America, San jose, CA*

HO-09. Nano-mechanics of Perfluoropolyether Films: Compression vs. Tension. *Q. Guo^{1,2}, P. Chung¹ and M.S. Jhon¹. Depart of Chemical Engineering and Data Storage Systems Center, Carnegie Mellon University, Pittsburgh, PA; 2. Seagate Technology, Fremont, CA*

HO-10. Ultraviolet Bonding of PFPE with Carbon Overcoat: Surface Energy and Spreading. *H. Chen², P. Chung¹ and M.S. Jhon¹. Depart of Chemical Engineering and Data Storage Systems Center, Carnegie Mellon University, Pittsburgh, PA; 2. Hewlett-Packard Company, San Diego, CA*

HO-11. Binary Mixture Lubricant Film of PFPE Lubricants. *P. Chung¹, H. Chen² and M.S. Jhon¹. Depart of Chemical Engineering and Data Storage Systems Center, Carnegie Mellon University, Pittsburgh, PA; 2. Hewlett-Packard Company, San Diego, CA*

HO-12. A Study on Design and Analysis of New Lubricant for Near Contact Recording. *D. Shirakawa¹ and K. Ohnishi¹. Asahi Glass Co., Ichihara-shi, Chiba, Japan*

HO-13. A new contact model for head disk interface (HDI) with ultrathin liquid film and ultrasmall spacing. *H. Matsuoka¹, H. Kokumai¹ and S. Fukui¹. Department of Applied Mathematics and Physics, Faculty of Engineering, Tottori University, Tottori, Japan*

HO-14. Density Dependence of Carbon/Magnetic layer for Corrosion/Scratch Resistance on Head-Disk-Interface. *H. Tani¹ and M. Shoda¹. Head media interface technology, Hitachi Global Storage Technologies Japan, Fujisawa-shi, Kanagawa-ken, Japan*

THURSDAY

Session HP
SOFT FILMS
(POSTER SESSION)
Alfredo Garcia-Arribas, Chair

HP-01. Crystal structure as an origin of high anisotropy field of FeCoB films with Ru underlayer. *A. Hashimoto¹, K. Hirata¹, T. Matsuu¹, S. Saito² and S. Nakagawa¹. Dept. of Physical Electronics, Tokyo Institute of Technology, Tokyo, Japan; 2. Electronic Engineering, Tohoku University, Sendai, Japan*

HP-02. Magnetic properties and crystallographic structure of Fe3Pt thin films on glass substrate. *S. Hsiao¹, S. Chen¹, Y. Hsu¹, H. Lee², W. Chang³ and F. Yuan⁴. Materials science and engineering, Feng Chia University, Taichung, Taiwan; 2. National Synchrotron Radiation Research Center, Hsinchu, Taiwan; 3. Physics, National Chung Cheng University, Chiayi, Taiwan; 4. Physics, Academia sinica, Taipei, Taiwan*

HP-03. Suppression Of Sm Segregation And Improvement In Thermal Stability By Introducing Ru Underlayer In Co-Sm Amorphous Films. *K. Ikeda^{1,2}, T. Suzuki¹ and T. Sato². R&D center, Taiyo Yuden Co., Ltd., Gunma, Japan; 2. Spin device technology center, Shinshu University, Nagano, Japan*

HP-04. Magnetic properties of FeCo films prepared by hydrogenous gas reactive sputtering. *X. Liu¹ and A. Morisako². Department of Information Engineering, Shinshu University, Nagano, Naganoken, Japan; 2. Spin device technology center, Shinshu University, Nagano, Nagano, Japan*

HP-05. Nanocrystalline permalloy thin films obtained by nitrogen IBAD. *P. Prieto*¹, J. Camarero², J.F. Marco³, E. Jimenez², J.M. Benayas¹ and J.M. Sanz¹ *1. Física Aplicada, Universidad Autónoma de Madrid, Madrid, Spain; 2. Física de la Materia Condensada, Universidad Autónoma de Madrid, Madrid, Spain; 3. Instituto de Química Física Rocasolano, CSIC, Madrid, Spain*

HP-06. Ultra-Soft and High Magnetic Moment CoFe Films Directly Electrodeposited from a B-Reducer Contained Solution. *B. Zong*¹, G. Han¹, L. Wang¹, G. Leonard¹, J. Sze¹, L. Shen², H. Tan², Y. Loh¹, B. Lim¹ and B. Liu¹ *1. SMI, Data Storage Institute, A-Star, Singapore, Singapore; 2. Institute of Materials Research & Engineering, A-Star, Singapore, Singapore*

HP-07. Soft-magnetic CoNiFeP alloy films for high frequency applications. *F.M. Rhen*¹ and *S. Roy*¹ *1. Microsystems Center, Tyndall National Institute, Cork, Ireland*

HP-08. Spin re-orientation transition in amorphous FeBSi thin-films submitted to thermal treatments. *P. Tiberto*¹, F. Celegato¹, M. Coisson¹ and F. Vinai¹ *1. INRIM, Torino, Italy*

HP-09. Electroplated Ni_xFe_{100-x}/FeCo Multi-layer Films for Perpendicular Write Heads. *Y. Miyake*¹, M. Matsuoka¹, M. Kato¹, H. Kanai¹ and Y. Uehara¹ *1. Fujitsu Ltd, Nagano, Japan*

HP-10. High temperature electrodeposited multilayer amorphous alloy suitable for integrated inductors. *P. McCloskey*¹, B. Jamieson¹, T. O'Donnell¹, D. Gardner², M. Morris³ and S. Roy¹ *1. Microsystems Center, Tyndall National Institute, Cork, Ireland; 2. Circuit Research lab, INTEL Corporation, Santa Clara, CA; 3. Chemistry department, University College Cork, Cork, Ireland*

HP-11. Magnetic properties of sputtered permalloy/molibdenum multilayers. *M. Romera*¹, M. Maicas¹, R. Ranchal², D. Ciudad¹, E. López² and P. Sánchez¹ *1. ISOM, Universidad Politécnica de Madrid, Madrid, Madrid, Spain; 2. Física de Materiales, Universidad Complutense de Madrid, Madrid, Madrid, Spain*

HP-12. Effects of capping layers on damping constants and magnetic properties of CoFeB. *J. Song*¹, C. Wang¹, S. Huang¹, C. Lai¹, W. Chen², S. Yang² and K. Shen² *1. Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan; 2. ERSO, Industrial Technology Research Institute, Hsinchu, Taiwan*

HP-13. Direct Observation of Barkhausen Avalanches during Nucleation-Mediated Magnetization Reversal on a nanoscale. *M. Im*¹, P. Fischer¹, D. Kim² and S. Shin³ *1. CXRO, LBNL, Berkeley, CA; 2. Department of Physics, Chungbuk National University, Cheongju 361-763, South Korea; 3. Department of Physics and Center for Nanospinics of Spintronic Materials, Korea Advanced Institute of Science and Technology, Daejeon 305-701, South Korea*

HP-14. Magnetotransport and exchange-bias in CoCu electrodeposited granular alloys. *M. Plaza*¹, L. Perez¹, M. Sánchez¹, A. Fernández-Pacheco^{2,3} and J. de Teresa² *1. Dpt. Física de Materiales, Universidad Complutense de Madrid, Madrid, Spain; 2. Instituto de Ciencia de Materiales de Aragón, CSIC-Universidad de Zaragoza, Zaragoza, Spain; 3. Instituto de Nanociencia de Aragón, Universidad de Zaragoza, Zaragoza, Spain*

HP-15. High magnetic moment soft thin films for flux concentrators. *I.G. Trindade*^{1,2}, J. Oliveira^{1,3}, J. Teixeira¹, R. Fermento¹, J.B. Sousa^{1,2}, S. Cardoso⁴, P.P. Freitas⁴, J.E. Snyder⁵ and A. Raghunathan⁵ *1. IFIMUP-IN, Porto, Portugal; 2. Physics, Faculdade de Ciências da Universidade do Porto, Porto, Portugal; 3. Faculdade de Ciências da Universidade do Minho, Braga, Portugal; 4. INESC-MN-IN, Lisboa, Portugal; 5. Wolfson Centre for Magnetism, School of Engineering, Cardiff University, Cardiff, United Kingdom*

Session HQ
DOMAIN WALLS IN NANOWIRES AND THIN FILMS
(POSTER SESSION)
Dorothee Petit, Chair

HQ-01. Controlling Domain Wall Pinning in Planar Nanowires with Transverse Field and its Application in a Magnetic Memory Cell. *D. Atkinson*¹, D.S. Eastwood¹ and L.K. Bogart¹ *1. Physics, Durham University, Durham, United Kingdom*

HQ-02. Bi-stable memory element based on pinned domain walls in pairs of notches. *E. Martinez*¹, L. Lopez-Diaz², O. Alejos³ and L. Torres² *1. Ingenieria Electromecanica, University of Burgos, Burgos, Burgos, Spain; 2. Física Aplicada, University of Salamanca, Salamanca, Spain; 3. Electricidad y Electronica, University of Valladolid, Valladolid, Spain*

HQ-03. Shingle shot detection of the magnetic domain wall motion by using the TMR effect. *K. Kondou*¹, N. Ohshima², S. Kasai¹, Y. Nakatani³ and T. Ono¹ *1. Institute for Chemical Research, Kyoto University, Uji, Kyoto, Japan; 2. Device Platforms Research Laboratories, NEC Corp., Sagami-hara, Kanagawa, Japan; 3. Department of Computer Science, University of Electro-communications, Chofu, Tokyo, Japan*

HQ-04. Domain wall injection study in spin valve system with different geometry reservoirs. *K. Cheng*^{1,2}, C. Yu¹, S. Lee¹, Y. Liou¹, Y. Yao³, J. Wu³ and J. Huang² *1. Institute of Physics., Academia Sinica., Taipei, Taiwan; 2. Department of Materials Science and Engineering, National Tsing-Hua University, Hsinchu, Taiwan; 3. Department of Materials Engineering, Tatung University, Taipei, Taiwan*

HQ-05. Magnetization reversal with domain wall motion in NiFe nanodevices with different pinning sites. *Y. Zhou*¹, D. Stickler², Y. Du¹, E. Ahmad¹, Z. Lu¹, H.P. Oepen², D. Wilton¹ and G. Pan¹ *1. Faculty of Technology, University of Plymouth, Plymouth, Devon, United Kingdom; 2. Institut für Angewandte Physik, Universität Hamburg, Jungiusstr, Hamburg, Germany*

HQ-06. Magnetoresistance of transverse and vortex domain walls in permalloy submicron wires. *C. Yu*¹, S. Lee¹, K. Cheng¹, D. Chen², E. Haung³ and Y. Liou¹ *1. physics, academia sinica, Taipei, Taiwan; 2. Materials Science & Engineering, Chiao Tung University, Hsinchu, Taiwan; 3. Materials Science & Engineering, University of Tennessee, Knoxville, TN*

HQ-07. Domain wall magnetoresistance effect in nanobridges. *Y. Chen*¹, J. Hsu¹, C. Yu², K. Cheng², S. Lee², Y. Liou² and Y. Yao² *1. Physics, National Taiwan University, Taipei, Taiwan; 2. Physics, Academia Sinica, Taipei, Taiwan*

HQ-08. Effect of period and linewidth on the magnetization reversal of thin film wire arrays. *S. Moralejo*¹, C. Redondo¹, F.J. Castano², C.A. Ross² and F. Castano¹ *1. Depart. Química Física, Univ. País Vasco, Lejona, Vizcaya, Spain; 2. Depart. of Material Science and Engineering, MIT, Cambridge, MA*

HQ-09. Edge Roughness effect on the magnetization reversal process of spin valve submicron wires. *T. Chiang^{1,2}, C. Yu¹, Y. Chen¹, S. Lee¹ and G. Guo^{2,1}* *1. Institute of physics, Academia sinica, Taipei, Taiwan; 2. Physics, National Taiwan University, Taipei, Taiwan*

HQ-10. Study on domain wall moving in a permalloy ring structure. *D. Chen¹, C. Yu² and Y. Yao^{3,1}* *1. Department of Material Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan; 2. Institute of Physics, Academia Sinica, Taipei, Taiwan; 3. The Department of Materials Engineering, Tatung University, Taipei, Taiwan*

HQ-11. Magnetic domain wall pinning by the stray field of a ferromagnetic dot array. *P.J. Metaxas^{1,3}, J. Jamet¹, J. Ferré¹, P. Zermatten², G. Gaudin², B. Rodmacq², A. Schuhl² and R.L. Stamps^{3,1}* *1. Laboratoire de Physique des Solides (UMR CNRS 8502), Université Paris-Sud, Orsay, France; 2. SPINTEC (URA 2512 CNRS/CEA), CEA, Grenoble, France; 3. School of Physics, University of Western Australia, Perth, WA, Australia*

HQ-12. Ratchet effects on domain wall motion in 2D magnetic amorphous thin film with arrays of asymmetric holes. *J.I. Martín¹, A. Pérez-Junquera¹, V.I. Marconi², A.B. Kolton², L.M. Álvarez-Prado¹, Y. Souche³, A. Alija¹, M. Vélez¹, J.V. Anguita⁴, J.M. Alameda¹ and J.R. Parrondo^{2,1}* *1. Departamento de Física, Universidad de Oviedo - CINN, Oviedo, Asturias, Spain; 2. Física Atómica, Molecular y Nuclear, and GISC, Universidad Complutense de Madrid, Madrid, Comunidad de Madrid, Spain; 3. NANO, Institut Néel, CNRS and Université Joseph Fourier, Grenoble, Grenoble, France; 4. Dispositivos, Sensores y Biosensores, Instituto de Microelectrónica de Madrid (CNM-CSIC), Madrid, Comunidad de Madrid, Spain*

THURSDAY
AFTERNOON
2:30

POLIVALENTE

Session HR
MgO MAGNETIC TUNNEL JUNCTIONS II
(POSTER SESSION)
Coriolan Tiusan, Chair

HR-01. Annealing temperature dependence of tunnel magnetoresistance in MgO-barrier magnetic tunnel junctions with CoFeB electrodes. *(Invited) S. Ikeda¹, J. Hayakawa², Y. Lee¹, K. Miura^{2,1}, H. Hasegawa^{1,2}, F. Matsukura¹ and H. Ohno¹* *1. Laboratory for Nanoelectronics and Spintronics, RIEC, Tohoku Univ., Sendai, Japan; 2. Advanced Research Laboratory, Hitachi, Ltd., Tokyo, Japan*

HR-02. Effects of MgO barrier thickness on magnetic anisotropy energy constant in perpendicularly magnetic tunnel junctions of (Co/Pd)_n/MgO/(Co/Pt)_n *J. Lee^{1,3}, C. Lee^{1,2}, L. Ye¹, S. Wang^{1,2}, Y. Wang¹, K. Lin⁴, Y. Chang⁴ and T. Wu^{1,2,1}* *1. Taiwan SPIN Research Center and Graduate School of Engineering Science and Technology, National Yunlin University of Science and Technology, Douliou, Taiwan; 2. Graduate school of materials science, National Yunlin University of Science and Technology, Douliou, Taiwan; 3. Graduate school of Engineering Science and Technology, National Yunlin University of Science and Technology, Douliou, Taiwan; 4. Laser Application Technology Center, Industrial Technology Research Institute, Tainan, Taiwan*

HR-03. Magnetoresistance Behavior of Bottom Exchange Biased Perpendicular Magnetic Tunnel Junction Based on Pd/Co Multilayers. *D. Lim¹, K. Kim¹, S. Lee¹, S. Kim² and W. Jeung^{3,1}* *1. Materials Science and Engineering, Korea University, Seoul, South Korea; 2. Mechanical Design and Automation Engineering, Seoul National University of Technology, Seoul, South Korea; 3. Korea Institute of Science and Technology, P.O.Box 131, Seoul, South Korea*

HR-04. Improvement of (100) orientation of MgO films deposited at room temperature for perpendicular MTJ. *H. Ohmori¹ and S. Nakagawa¹* *1. Dept. of Physical Electronics, Tokyo Institute of Technology, Tokyo, Japan*

HR-05. Magnetic tunnel junctions formed by oxidation of Mg. *W. Raberg¹, T. Bever¹, M. Hawranek^{1,2}, S. Koss^{1,3}, S. Schmitt¹ and J. Zimmer¹* *1. Technology development Sense & Control, Infineon Technologies AG, Neubiberg, Germany; 2. Institut für Materialwissenschaften, Technische Universität Darmstadt, Darmstadt, Germany; 3. Institut für Festkörperphysik, Universität Hannover, Hannover, Germany*

HR-06. Influence of boron concentration on tunnel magnetoresistance in CoFeB/MgO/CoFeB magnetic tunnel junctions. *K. Tsunekawa¹, Y. Nagamine¹, Y. Choi¹, F. Ernult¹, D.D. Djayaprawira¹ and Y. Kitamoto^{2,1}* *1. Electronic Devices Engineering Headquarters, Canon ANELVA Corp., Kawasaki-shi, Kanagawa, Japan; 2. Tokyo Institute of Technology, Yokohama-shi, Kanagawa, Japan*

HR-07. Temperature dependence of magnetoresistance in epitaxial Fe/MgO/Fe/IrMn magnetic tunnel junctions. *S. Wang^{1,2}, R. Ward¹, G. Du², X. Han², C. Wang³ and A. Kohn^{3,1}* *1. Department of Physics, University of Oxford, Oxford, United Kingdom; 2. Institute of Physics, Chinese Academy of Sciences, Beijing, China; 3. Department of Materials, University of Oxford, Oxford, United Kingdom*

HR-08. The XRD analysis of pseudo and exchange bias spin valve of MgO based magnetic tunnel junctions. *J. Kanak¹, P. Wisniewski², A. Zaleski¹, S. Cardoso², P.P. Freitas² and T. Stobiecki^{1,1}* *1. AGH University of Science and Technology, Krakow, Poland; 2. INESC Microsystems and Nanotechnologies, Lisbon, Portugal*

HR-09. The electrical properties of the radically oxidized MgO prepared in different oxidation condition. *C. Shen¹, S. Yang¹, C. Yen¹, W. Chen¹, Y. Lee¹, D. Wang¹, C. Tsai¹, C. Hung¹, K. Shen¹ and M. Kao^{1,1}* *1. Electronics and Optoelectronics Research Lab (EOL), Industrial Technology Research Institute (ITRI), Hsinchu, Taiwan*

HR-10. Effect of Thermal Treatment on Chemical States of CoFeB/MgO/CoFeB Tunnel Junctions. *Y. Han¹, S. Lee¹, J. Hong¹, M. Jung² and H. Shin^{2,1}* *1. Materials Science and Engineering, Yonsei University, Seoul, South Korea; 2. Pohang Accelerator Laboratory, POSTECH, Pohang, Kyungbuk, South Korea*

HR-11. Ab initio calculations of the TMR in magnetic tunnel junctions (MTJ): application to Fe/MgO/Fe. *I. Arias¹, J.I. Cerdá¹ and M. Muñoz^{1,1}* *1. Intercaras y crecimiento, Instituto de Ciencia de Materiales de Madrid, Madrid, Madrid, Spain*

HR-12. Substrate biasing effect on the MgO (001) growth in CoFeB/MgO/CoFeB TMR junctions. *G. Choi¹, W. Lim¹ and T. Lee¹* *1. Department of Materials Science and Engineering, KAIST, Daejeon, South Korea*

HR-13. The bias voltage dependence of inverted magnetoresistance on the annealing temperature in MgO-based magnetic tunnel junctions. *J. Feng¹, G. Feng¹ and J. Coey¹*. *CRANN and school of physics, Trinity College, Dublin, Ireland*

HR-14. Detection of an infra red magnetorefractive effect from a layered Fe/MgO/Fe magnetic tunnel junction. *R.T. Mennicke¹, R. Berryman¹, F. Ernult², H. Wang², Y. Nogi², J.A. Matthew¹, S.M. Thompson¹, S. Mitani² and K. Takanashi²*. *1. Physics, University of York, York, North Yorkshire, United Kingdom; 2. Institute for Materials Research, Tohoku University, Sendai, Miyagi, Japan*

HR-15. Low Frequency Noise in MgO Magnetic Tunnel Junctions: Hooge's Parameter Dependence on Bias Current Density. *J.M. Almeida^{1,2} and P.P. Freitas^{1,2}*. *1. INESC - MN, Lisbon, Portugal; 2. Physics, IST, Lisbon, Portugal*

HR-16. Magnetization reversal processes of nanostructured magnetic tunnel junction rings. *C. Chen¹, C. Chao¹, C. Kuo¹, J. Ou¹, L. Horng¹, J. Wu¹, T. Wu², J. Yang³, S. Isogami⁴, M. Tsunoda⁴ and M. Takahashi⁴*. *1. Taiwan SPIN Research Center, National Changhua University of Education, Changhua, Taiwan; 2. Taiwan SPIN Research Center, National Yunlin University of Science & Technology, Yunlin, Taiwan; 3. Institute of Optoelectronic Sciences, National Taiwan Ocean University, Keelung, Taiwan; 4. Graduate school of Electronic Engineering, Tohoku University, Sendai, Japan*

THURSDAY
AFTERNOON
2:30

POLIVALENTE

Session HS AB INITIO CALCULATIONS (POSTER SESSION)

Oleg Mryasov, Chair
Laszlo Szunyogh, Chair

HS-01. First-principles calculations of structural and magnetic properties of Fe/MgO/Fe with interfacial Mg vacancy. *C. Kim¹, G. Yoon¹ and Y. Chung¹*. *1. Materials Science and Engineering, Hanyang University, Seoul, South Korea*

HS-02. Ab-initio spin-dependent electronic transport calculations of MTJ with low band-gap insulating oxides with rock salt structure. *A. Furuya¹, A. Fujisaki¹, H. Kanai², K. Noma², K. Kobayashi² and Y. Uehara²*. *1. Simulation Technology Development Division, FUJITSU Advanced Technologies Ltd, Kawasaki, kanagawa, Japan; 2. Head Division, Storage Products Group, Fujitsu Ltd, Nagano, Nagano, Japan*

HS-03. Inhomogeneity and magnetism in diluted magnetic semiconductors. *B. Sanyal¹, R. Knut¹, O. Granäs¹, D.M. Iusan¹, O. Karis¹ and O. Eriksson¹*. *1. Department of Physics, Uppsala University, Uppsala, Sweden*

HS-04. Interface magnetism in Fe₂O₃-FeTiO₃ heterostructures. *S. Sadat Nabi¹ and R. Pentcheva¹*. *1. department of earth and environmental sciences, section crystallography, Ludwig Maximilian University of Munich, Munich, Germany*

HS-05. Charge, magnetic and orbital order at perovskite interfaces. *R. Pentcheva¹ and W.E. Pickett²*. *1. Department of Earth and Environmental Sciences, Section Crystallography, University of Munich, Munich, Germany; 2. Department of Physics, University of California, Davis, CA*

HS-06. Magnetism of conduction band, exchange interactions and magneto-caloric effects in pure hcp Gd: a first-principles calculations. *S. Khmelevskiy¹, A.V. Ruban², I. Turek³ and P. Mohn¹*. *1. Center for Computational Materials Science, Vienna Technical University, Vienna, Austria; 2. Royal Unicersity of Technology, Stockholm, Sweden; 3. Charles University, Prague, Czech Republic*

HS-07. Ab-initio magneto-optical properties of bcc Ni/Ni(100). *C. Etz¹, A. Vernes¹, L. Szunyogh^{1,2} and P. Weinberger¹*. *1. Center for Computational Materials Science, Vienna University of Technology, Vienna, Austria; 2. Department of Theoretical Physics, Budapest University of Technology and Economics, Budapest, Hungary*

HS-08. Influence of external magnetic field on the resistivity of a one-dimensional Neel type magnetic domain wall in presence of Rashba spin-orbit coupling. *M. Ghanaatshoar¹, V. Fallahi¹, M.M. Tehranchi¹ and A. Phirouznia²*. *1. Laser and Plasma research institute, Shahid Beheshti University, Tehran, Tehran, Iran; 2. Department of physics, Azarbaijan University of Tarbiat Moallem, Tabriz, Eastern Azarbaijan, Iran*

HS-09. *Ab-initio* study on the magnetic structures in the ordered Mn₃Pt alloy. *Y. Kota¹, H. Tsuchiura¹ and A. Sakuma¹*. *1. Applied Physics, Tohoku University, Sendai, Japan*

HS-10. Half-metallicity of the bulk and the (001) surface for full Heusler alloy Co₂HfSi: a first-principles study. *Y. Jin¹ and J. Lee¹*. *1. Physics, Inha University, Incheon, South Korea*

HS-11. Magnetic properties of the antiperovskite Co₄N(001) surfaces: a first-principles study. *I. Kim¹, B. Bialek² and J. Lee²*. *1. Grad. Inst. Ferrous Tech. (GIFT), POSTECH, Pohang, South Korea; 2. Physics, Inha University, Incheon, South Korea*

HS-12. A first principles study of Thiol-Capped Au Nanoparticles. *R. Cuadrado¹ and J. Cerdá¹*. *1. Intercaras y Crecimiento, Instituto de Ciencia de Materiales de Madrid, Madrid, Madrid, Spain*

HS-13. The Study of Magnetic Properties of Fe₂Sm Using Ab- Initio Calculation. *M. Imaizumi¹, L.C. Varanda² and M. Jafellicci Jr³*. *1. Fisica, Universidade Estadual Julio de Mesquita Filho, Bauru, S.Paulo, Brazil; 2. Química, Universidade de São Paulo, São Carlos, São Paulo, Brazil; 3. Química, Universidade Estadual Paulista Júlio de Mesquita Filho, Araraquara, São Paulo, Brazil*

HS-14. Energy spectrum of S=1/2 Heisenberg systems via a recursive diagonalization method. *F.C. Souza¹ and V.L. Líbero¹*. *1. Departamento de Física e Informática, Instituto de Física de São Carlos, Universidade de São Paulo, São Carlos, São Paulo, Brazil*

HS-15. Density Functional Theory for Heisenberg Spin-1/2 Chains With Bond Defects. *V.L. Líbero¹ and P.H. Penteado¹*. *1. Departamento de Física e Informática, Instituto de Física de São Carlos, Universidade de São Paulo, São Carlos, São Paulo, Brazil*

HS-16. Ab initio DFT study of half-metallic character in $\text{Sr}_2\text{CoReO}_6$ complex perovskite. *J. Roa-Rojas¹, M. Bonilla¹, J.A. Rodriguez¹, F. Fajardo¹ and D.A. Landinez-Tellez¹*. *Dept. of Physics, Universidad Nacional de Colombia, Bogotá, D. C., Colombia*

THURSDAY
AFTERNOON
2:30

POLIVALENTE

Session HT
RECORDING SYSTEMS, CODING AND CHANNELS-II
(POSTER SESSION)

Jae Moon, Chair

HT-01. Combinations of decoding algorithm for LDPC codes by tensor product decoding. *H. Kamabe¹*. *Information Science, Gifu University, Gifu, Gifu, Japan*

HT-02. Performance Evaluation of Combined Post-processor Based on Likely Error Pattern and Parity Check Targeting under Write Pre-compensation in PMR Channel with NLTS. *Y. Okamoto¹, T. Bushisue¹, Y. Nakanura¹, H. Osawa¹ and H. Muraoka²*. *1. Graduate School of Science and Engineering, Ehime University, Matsuyama, Ehime, Japan; 2. RIEC, Tohoku University, Sendai, Japan*

HT-03. Performance comparison of various error correcting strategies using perpendicular magnetic recording data series. *S. Mita¹ and H. Matsui¹*. *1. Toyota Technological Institute, Nagoya, Japan*

HT-04. EPCC-based Channel-Optimized LDPC coding. *H.S. Alhussien¹ and J. Moon¹*. *1. CDSLAB, Electrical and Computer Engineering, University of Minnesota Twin Cities, Minneapolis, MN*

HT-05. On Imposing an RLL Constraint without Explicit RLL Coding. *J. Park¹ and J. Moon¹*. *1. Electrical and Computer Engineering, University of Minnesota, Minneapolis, MN*

HT-06. On the use of averaging to estimate the dibit response. *M. Ting¹*. *1. Seagate Technology, Pittsburgh, PA*

HT-07. Two-Dimensional Pulse Response and Media Noise Modeling for Bit-Patterned Media Channels. *S. Nabavi^{1,2}, V. Bhagavatula^{1,2} and J.A. Bain^{1,2}*. *1. Data Storage Systems Center (DSSC), Pittsburgh, PA; 2. ECE, Carnegie Mellon University, Pittsburgh, PA*

HT-08. Soft Feedback Equalization for Patterned Media Storage. *M. Keskinöz¹*. *1. Electronics Engineering, Sabanci University, Istanbul, Turkey*

HT-09. Signal Modeling for Ultra-high Density Bit Patterned Media and Performance Evaluation. *S. Zhang¹, Z. Qin¹ and X. Zou¹*. *1. Data Storage Institute, Singapore, Singapore*

INTERMAG 2008

HT-10. Equalization and detection for patterned media recording. *S. Karakulak¹, P.H. Siegel¹, J.K. Wolf¹ and H. Bertram^{1,2}*. *1. Electrical and Computer Engineering Dept., Center for Magnetic Recording Research, UCSD, La Jolla, CA; 2. Hitachi Global Storage Technologies, San Jose, CA*

HT-11. Understanding sources of errors in bit patterned media to improve read channel performance. *Y. Shi¹, P.W. Nutter¹ and J.J. Miles¹*. *1. School of Computer Science, The University of Manchester, Manchester, United Kingdom*

HT-12. Global timing control for tape storage channels. *S. Ölçer¹, J. Jelitto¹ and R.A. Hutchins²*. *1. IBM Zurich Research Laboratory, Rüschlikon, Zürich, Switzerland; 2. IBM STG, Tucson, AZ*

THURSDAY
AFTERNOON
2:30

Multiferroic and Magnetoelectric Materials.

J. F. Scott

Earth Sciences, Cambridge University, Cambridge, United Kingdom

J. F. Scott

Cambridge University

In this tutorial I will do five things: First a discussion is given of the general symmetry ideas and notation used to describe materials that are simultaneously ferromagnetic (or antiferromagnetic) and ferroelectric (or antiferroelectric). A comparison is given with electrets and with pyroelectrics, some of which can be ferroelectric (e.g., GeTe), depending upon their electrical conductivity, and some of which (e.g., ZnO or CdS wurtzite structures) can be pyroelectric but not ferroelectric. This point is used to discuss ZnO:Li, which many authors claim to be ferroelectric.

In the second part of the talk I will give a brief status report on random access memories (RAMs) and describe the present state of ferroelectric RAMs (FRAMs), magnetic MRAMs, and explain why multiferroelectric magnetoelectric RAMs are potentially attractive: Fast, low-power, voltage-driven WRITE operations, followed by nondestructive magnetic READ operations (which require no re-set).

In the third part of the tutorial I will describe the basic physics of switching, and how this controls the speed of ferroelectric and magnetic domain walls in devices [Catalan et al.], as well as the basic phenomenon of magnetocapacitance [Scott; Glass et al.]. I show that magnetodielectric effects in which the dielectric constant changes near T_{Neel} are normally small ($<1\%$), negative, and scale with temperature T as the magnetism $M(T)$ does or as the magnetic energy $\langle S_j \cdot S_{j+1} \rangle$ does. By comparison, external artifacts due to Maxwell-Wagner space charge can be very large ($>1000\%$), positive, and have T -dependences which do not vary as $M(T)$ [Catalan; Catalan and Scott].

In the fourth part of the talk I will discuss the extension of present searches for room-temperature multiferroics from oxides to fluorides [Blinc], with illustrations from $\text{K}_3\text{Fe}_5\text{F}_{15}$ ($T_c = 125\text{K}$) and $\text{Sr}_3(\text{FeF}_6)_2$.

Finally, in the last part of the tutorial I will provide an up-date on BiFeO_3 , the most popular multiferroic material at present; I will emphasize the new, unpublished, discoveries [Palai et al.] of a metal-insulator transition in this material at 931C (atmospheric pressure) and 47 GPa (room temperature). This is shown schematically in Figure 1. This is the only known metal-insulator in a ferroelectric magnet. And I will discuss the new [Singh et al., arXiv 2007; Cazayous et al., arXiv 2007] and unexpected magnetic spin-reorientation transition at 200K (one sample) or 140K (another sample), and the spin-glass transition at 29.4K .

Multiferroic materials: from bulk to thin films.*W. Prellier**ENSICAEN, CNRS, Caen, France*

Transition metal oxides with perovskite-type structure exhibit a rich spectrum of interesting properties, including magnetism, ferroelectricity, strongly correlated electron behaviour, superconductivity, magnetoresistance, half metals etc., which have become the research area of great interest among the scientific community for decades. Previously, perovskite oxides were considered as pure academic materials, but the discovery of superconductivity at high temperatures in cuprates and soon after of colossal magnetoresistance in manganites, makes that they are now regarded as potential candidates for various applications in electronics, such as memory elements, actuators and sensors.

There exist very few materials which exhibit multiple functional properties -one such class of material is called multiferroics. Multiferroics are interesting because they possess simultaneously ferromagnetic and ferroelectric polarization and there might be a coupling between them. Thus, the magnetic polarization could be switched by applying an electric field likewise the ferroelectric polarization can be switched by applying a magnetic field. As a consequence, they offer rich physics and novel devices concepts, which recently nested a great interest among the researchers. During this tutorial, the recent experimental status, both in bulk single-phase and in thin film form, will be presented. Current study on the ceramic compounds in bulk form including $\text{Bi}(\text{Fe},\text{Mn})\text{O}_3$, REMnO_3 and the series of $\text{RE}\text{Mn}_2\text{O}_5$ single crystals (RE=rare earth) will be discussed in the first part. A detailed overview on multiferroic thin films and artificially grown structures (multilayers and nanocomposites) will be presented in a second part. A peculiar attention will be given to the BiFeO_3 compound, which has been among the one of the few naturally existing multiferroic materials, that has been studied extensively in the past few decades, both in the form of bulk and thin films. Finally, some possible applications in spintronics will be discussed.

This work was carried out in the frame of the Network Of Excellence FAME (FP6-5001159-1), the STREP project MANipulating the COpling in Multiferroic FILms (NMP3-CT-2006-033221) supported by the European Commission and by the CNRS, France. Partial support from the ANR (NT05-1-45177, NT05-3-41793) is also acknowledged.

Multiferroic Composites: Magnetoelectric Effects, Sensors and High Frequency Devices.*G. Srinivasan**Physics, Oakland University, Rochester, MI*

Multiferroics with two or more ferroic (ferroelectric, ferro/ferri/anti-ferromagnetic, ferroelastic) orderings have attracted considerable interests in recent years. Single-phase multiferroics are rare and their magnetoelectric (ME) responses are either weak or occur at temperatures too low for practical applications. Ferromagnetic-piezoelectric composites, however, show strong ME coupling at ambient temperatures. The ME effect here is a product-property mediated by elastic deformation, i.e., an electric polarization is induced by an ac magnetic field in the presence of a dc bias field. So far, three kinds of ME composites have been investigated: (a) ferrite and piezoelectric ceramics (e.g., lead-zirconate-titanate), (b) magnetic metals/alloys and piezoelectric ceramics, and (c) magnetic alloys and piezoelectric polymers. The composites show a rich variety of phenomena including giant low-frequency ME interactions and enhanced coupling when magnetic and/or electric sub-systems are at resonance.

This tutorial presentation will focus on recent developments in the physics, materials science and applications of composite multiferroics.

We will discuss single crystal and polycrystalline bulk and layered composites; epitaxial heterostructures; ferrites, shape memory alloys, or transition metal/alloy based multiferroics; polymer ferroelectric-ferromagnetic composites; ME characterization techniques and the theory of ME phenomena. The potential use of composites for magnetic field sensors and transducers, memory devices, and dual electric and magnetic field tunable microwave and mm-wave devices will also be discussed.

The review will conclude with an outlook on future possibilities and challenges in the field of multiferroic magnetoelectric composites.

Magneto-optical and spin transfer switching properties of current-perpendicular-to plane spin valves with perpendicular magnetic anisotropy.

K. Aoshima¹, N. Funabashi¹, K. Machida¹, Y. Miyamoto¹, N. Kawamura¹, K. Kuga¹, N. Shimidzu¹, T. Kimura², Y. Otani²

1. Science & Technical Research Laboratories, Japan Broadcasting Corp., Setagaya, Japan; 2. The Institute for Solid State Physics, The Tokyo University, Kashiwa, Japan

1. Introduction

Magneto-optical (MO) observation of spin transfer switching (STS) by visible light has been demonstrated using the current-perpendicular-to-plane spin-valve (CPP-SV) device with a transparent top electrode [1]. However, because of its in-plane magnetic anisotropy, the detected MO signal was not sufficient for useful applications, such as a MO light modulation device driven by STS or a time resolved STS observation [1]. To accomplish those MO devices driven by STS, large MO effect and an efficient spin transfer are both required at a same time. It is well-known that magnetic materials with perpendicular anisotropy have larger MO effect compare to that with in-plane anisotropy. Although the STS with the perpendicular anisotropy have been succeeded for MRAM application to reduce switching field [2], MO properties of the sandwich structure such as the CPP-SV structure have not been investigated. In this paper we show MO properties of CPP-SV stacks with perpendicular anisotropy using GdFe free layer, as well as their STS properties.

2. Experiment

The film stacks of the CPP-SV is substrate/bottom electrode/Tb-Fe-Co(20)/Co₇₅Fe₂₅(1)/Cu(6)/Gd-Fe(t)/Cu(3)/Ru(3) (in nm). The films were deposited by DC magnetron sputtering system and annealed at 190 °C in vacuum without magnetic field. Tb₃₂-Fe-Co (at%) and Gd₃₀Fe₇₀ (at%) layers serve as the pinned and the free layer, respectively. In these compositions, magnetic moment direction of Tb and Gd are aligned parallel with the applied magnetic field at room temperature [3]. MO measurements were carried out in the wave length of 780 nm. CPP-SV devices were fabricated by electron beam lithography and lift-off method. Transport properties were measured by 4-point probe method. STS properties were evaluated by pulsed current of which duration is 1 μs at a magnetic field of -70 Oe. Positive current corresponds to current flowing from the bottom to the top electrode.

3. Results and Discussion

The inset of fig. 1 shows Kerr rotation (θ_k) for Gd-Fe 10 nm sample versus applied field. It has steps which correspond to the switching of the Gd-Fe (smaller coercivity, $H_c \approx 300$ Oe) and Tb-Fe-Co (larger $H_c \approx 6.5$ kOe) layer. This indicates that Gd-Fe and Tb-Fe-Co layer exhibit sufficient property for the free and the pinned layer respectively. Figure 1 shows the θ_k of Gd-Fe for various thickness. θ_k is about 0.18 ° for samples which thickness is more than 20 nm, and decreased with a decrease of the Gd-Fe thickness for thinner than 20 nm. This reduction was explained that the Gd-Fe thickness became thinner (<20nm) than a penetration depth of the light. And a sign of θ_k was changed from positive to negative for the samples thickness of 6 nm or less. Cause of the sign change is not clear here. But we speculate that slight composition change may occur near the interface of GdFe due to an intermixing. Figure 2 (a) shows schematic figure of the fabricated CPP-SV and direction of current flow and magnetic field. Figure 2 (b) and (c) show Magneto Resistance (MR) response curve and STS property of CPP-SV with Gd-Fe 10 nm, respectively. The MR ratio was about 0.06%. Small MR is attributed to large resistivity of TbFeCo and GdFe (about 200 μΩcm). Switching current from high to low resistance and low to high resistance were -3.1×10^7 A/cm² and 1.6×10^7 A/cm², respectively. Resistance change was about 0.3 mΩ which is consistent

with the resistance change obtained from the MR curve. These results demonstrate that STS was succeeded with GdFe free layer which shows large Kerr rotation. CPP-SV using GdFe free layer with perpendicular anisotropy would have great potential to improve light modulation property of those MO devices.

Time-resolved magnetization switching induced by spin-transfer in Magnetic MgO tunnel junctions.

T. Devolder¹, J. Hayakawa^{2,3}, K. Ito², H. Takahashi², S. Ikeda³, P. Crozat¹, J. V. Kim¹, C. Chappert¹, H. Ohno³

1. Institut d'Electronique Fondamentale, ORSAY Cedex, France; 2. Advanced Research Laboratory, Hitachi, Ltd, Tokyo, Japan; 3. Laboratory for Nanoelectronics and Spintronics,, Research Institute of Electrical Communication, Tohoku University, Sendai, Japan

The spin-transfer torque can switch the magnetization of a nanomagnet [1], which is considered as a promising route to ensure the scalability of programming in high density Magnetic Random Access Memories. One important issue is whether fast writing can be achieved in a routine manner in the magnetic tunnel junctions (MTJ) with high magneto-resistance ratios that are needed for efficient memory reading. In this paper, we study spin-transfer switching induced by fast voltage pulses in MgO-based magnetic tunnel junctions.

Our devices are patterned from a MTJ of composition CoFeB (2.5 nm, free layer)/MgO (0.9) /CoFeB (6)/Ru(0.8)/CoFe(5)/MnIr(8). The MTJ is patterned in a pillar-shaped rectangle of size 100x300 nm. The long axis is parallel to the pinning direction.

The quasi-static properties of the MTJ are consistent with the uniaxial anisotropy expected from the sample elongated shape. The two remanent states have resistances of 286 and 364 Ω . Spin transfer loops (i.e. I-V curves) indicate quasi-static switching voltages to be $0.6 \text{ V} \pm 0.1 \text{ V}$ for the AP to P transition and $0.6 \text{ V} \pm 0.1 \text{ V}$ for the P to AP transition.

For time-resolved switching experiments, we first prepare the sample in the remanent P state using a proper field history. A (negative) voltage step $V_{\text{step}} = -0.5 \text{ V}$ with a rise time of 55 ps is then sent to a 50 Ω line feeding the sample. Due to the reflection at the high impedance device, the voltage across the device is almost twice this incident voltage, hence it is near -1V. After amplification, the transmitted voltage is recorded with either a sampling (i.e. stroboscopic) oscilloscope with a bandwidth of 26 GHz (Fig.1A) or a single-shot oscilloscope with a bandwidth of 13 GHz (Fig.1B). With these set-up, the transmitted voltage abruptly decreases when the device transits in the high resistance state (Fig. 1A inset).

From single shot switching records (Fig. 1B), we could determine individual switching instants, and the distribution thereof. They are randomly distributed with a mean value of 5.3 ns. Note that the widely used stroboscopic techniques, such as pump-probe optical techniques [2] or electrical sampling (Fig.1A or [3]) can fail to describe accurately the switching main characters. Indeed in these techniques, any time-resolved curve must be reconstructed from a large number of switching tests, and the present stochasticity renders this reconstruction inoperative.

Knowing the shape of the current pulse, we translate the voltage traces into magneto-resistance traces (Fig. 2). Three main interesting features are worth noticing. First, there is an incubation delay before anything happens after the onset of the voltage step. The resistance stays quiet during that delay. Secondly, there is a fast transition from P to AP resistance that takes circa 0.4 ns. Finally, there is a large ringing after switching. To study this ringing, we have averaged 20 traces, those traces having been selected to have the same switching instant 1.650 ns. This averaging procedure (Fig. 2A) confirms that the ringing is reproducible.

We have repeated this procedure with other selected switching instants (Fig. 2B). It is striking to notice once the stochastically varying incubation delay is passed, the resulting time evolutions of the electrical resistance seem identical within the measurement accuracy. This is our central con-

clusion: the switching instant fluctuates but the resistive signature of the switching trajectory after the incubation delay is deterministic.

Figures

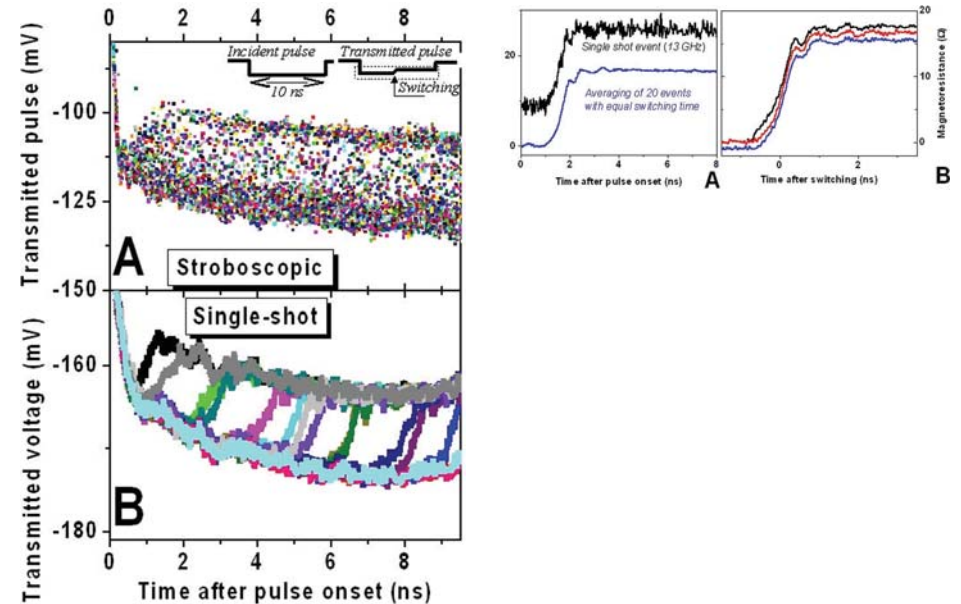

Figure 1: (color online): Inset: sketch of the incident and transmitted voltage pulses when a device switches from P to AP. The dotted line rectangle zooms on the pulse plateau. Main panel: zoom on the plateau of the transmitted voltage. Each switching trials is displayed with a different color. Panel A is measured with a sampling 26 GHz oscilloscope. Panel B: is measured with a single shot 13 GHz oscilloscope.

Figure 2: (color online): Panel A: top curve: single shot switching event measured with 13 GHz bandwidth. Bottom curve; average of 20 single shot switching events having the same switching instant. Panel B: average of single shot switching events with switching instants of 0.7 (black), 2.8 (red), and 4.9 ns (blue). Data are plotted versus time elapsed after switching, and are vertically offset.

Coherent control of spin transfer torque magnetization dynamics.

S. Serrano-Guisan¹, K. Rott², G. Reiss², B. Ocker³, J. Langer³, H. W. Schumacher¹

1. Physikalisch-Technische Bundesanstalt, Braunschweig, Germany; 2. Department of Physics, University of Bielefeld, Bielefeld, Germany; 3. Singulus Nano Deposition Technologies GmbH, Kahl am Main, Germany

We study time resolved precessional magnetization dynamics induced by spin momentum transfer in CoFeB/MgO/CoFeB based magnetic tunnelling junctions (MTJ). Our experiments are performed at room temperature on elliptical MTJ nanopillars having lateral dimensions down to 120 nm [1]. The MTJ stacks were sputter deposited in a Singulus TIMARIS 10 Target PVD module. In static magnetic fields the CoFeB free layers of the nanopillars show a well defined mainly single domain switching behaviour. Spin transfer torque precession of the CoFeB free layer is excited by application of ultra short current pulses with pulse duration from 0.16 to 5 ns duration and with current densities around 10^6 A/cm². The time resolved precession of the free layer is studied by measuring the time resolved tunnelling magneto resistance (TMR) change of the MTJ using a fast sampling oscilloscope. Superposition of a weak dc bias current on the excitation pulse allows detecting both the spin torque precession during the current pulse and the magnetization ringing after pulse termination (Fig. 1).

From the decay of the ringing the effective Gilbert damping parameter α of the MTJ free layer is derived (Fig 1a). Additionally, the modification of α under the influence of STT is accessible from the decay of the STT precession during a long current pulse (Fig. 1b). Depending on the relative orientation the free and pinned layer magnetization the STT leads to an enhanced or reduced effective damping in agreement with theoretical predictions.

The magnetization ringing further provides information on the non-equilibrium orientation of the free layer magnetization upon pulse termination. This is of major importance e.g. to evaluate the reliability of spin torque magnetization switching employing ultra short current pulses. We show that by adapting the duration of the excitation pulse to integer multiples of the period of the spin torque precession the magnetization ringing can be coherently suppressed (Fig. 2). Such coherent control of spin torque dynamics is a prerequisite for ultra fast ballistic spin transfer torque magnetization reversal.

STT magnetization reversal under application of a 10 mT hard axis bias field is shown in Fig. 3. Fig. 3(a) shows switching by a 5 ns current pulse of 4×10^6 A/cm² current density. At the pulse inset the magnetization performs a precessional overshoot followed by damped precession. Upon pulse termination the magnetization relaxes to the reversed equilibrium state.

Figure 3(b) shows biased STT switching by 100 and 500 ps pulses. Again, the initial overshoot is observed. It is now followed by a pronounced magnetization ringing indicating non equilibrium magnetization alignment upon pulse termination. Furthermore the reduced voltage signal measured in the reversed state speaks for a reduced switching reliability.

Finally Fig. 3(c) shows switching for a 1 ns pulse. Here the pulse duration is coherently matched to the duration of the precessional overshoot observed for the 5 ns pulse. Upon pulse decay the magnetization is near the reversed equilibrium state and the magnetization ringing is suppressed. Furthermore, for the coherently optimized pulse a high switching reliability is found.

Such biased quasi ballistic STT magnetization reversal could allow ultra fast and yet reliable STT memory operation.

Introduction

Spin-transfer magnetization switching has received increasing attention as a novel magnetization switching technique without external magnetic field. This technique has a potential to lower the writing current in the magnetoresistive random access memory (MRAM) compared with the classical magnetic field writing. Coherent amplification of the precession and successive switching of the free-layer magnetization in a CPP-GMR device was demonstrated by I. N. Krivorotov et al. [1] at low temperature (40 K). For real application, however, the mechanism of the room temperature switching of the magnetic tunnel junctions (MTJs) where the thermal fluctuation may play important role [2,3] must be clarified. In this study, we performed time-resolved measurements of current-induced magnetization switching in MgO-based MTJs using a high speed single-shot oscilloscope to understand the switching process.

Experimental method

The layer structure of the measured MTJs is MgO substrate/buffer/PtMn/CoFe/Ru/CoFeB(3.0)/Mg(0.6)/MgO(0.6)/CoFeB(2.0)/cap (numbers are thickness in nm). Pillars of $70 \times 160 \text{ nm}^2$ in size were fabricated from the film using an electron-beam lithography and an Ar-ion milling. Applied magnetic field direction and MTJ's easy axis inclined by 30 degrees. Schematic illustration of the measurement system is shown in figure 1. After initializing the magnetization to the parallel state, a DC pulse with duration time of 10 ns was applied from a pulse generator to the MTJ through a power divider. A reflected pulse from the MTJ was recorded by the high-speed storage oscilloscope (Band width: 18 GHz, Sampling rate: 50 GS/s).

Results

In figure 2, the typical reflected pulse signals are shown. Amplitude of the applied current pulse was 2.0 mA ($J = 1.8 \times 10^7 \text{ A/cm}^2$). In the case of light color line, we can see no voltage transition in the reflected pulse signal. In contrast, in the case of dark color line, clear voltage step appears after a waiting time of about 5 ns. Here, we define the waiting time as the time delay between the initial rise of the reflected pulse signal and the onset of the voltage step. The transition indicates a magnetization switching from the parallel to the anti-parallel state. Although considerably long waiting time was observed, the transition time from parallel state to the anti-parallel state was found to be very short (300 ps for example). This result agrees well with micromagnetic calculations [3]. Repetitive several hundreds measurements were performed under the same condition with different current amplitudes. The distribution of the waiting time in the switching process appears in the figure 3. The amplitudes of the applied currents were 2.0 mA ($J = 1.8 \times 10^7 \text{ A/cm}^2$) and 1.7 mA ($J = 1.5 \times 10^7 \text{ A/cm}^2$). We can clearly see that the distribution of the waiting time shift to the longer time range with decreasing the current amplitude. Further analyses of the data revealed a correlation between the waiting time and the transition time. We will try to discuss the detailed switching mechanism in the talk.

Observation of intermediate states in large magnetic tunnel junctions with composite free layer.

X. Yao¹, R. Malmhall², R. Ranjan², J. Wang¹

1. MINT Center & Electrical and Computer Engineering Department, Univ. Of Minnesota, Minneapolis, MN; 2. Yadav Technology, Fremont, CA

Current-induced magnetization switching (CIMS) has advantages of device scaling compared to the traditional field-induced switching. Several groups reported the existence of an intermediate state in GMR devices due to the multidomain formation [1-3] by the spin-polarized current. In this paper, we discuss the current-driven switching behaviour of large MTJ devices with a composite free layer, with the emphasis on the intermediate state observation. To generate and control reversible intermediate states is one of ways to realize the multilevel spintronic devices such as MRAM.

The composite free layer structure is CoFeB/CoFeB-oxide/CoFeB. CoFeB-oxide layer acts as a nano-current-confined (NCC) structure, which can reduce the critical switching current density (J_c) of the devices [4,5]. Same as FeSiO NCC layer, CoFe prefers to form the cores and the oxide material together with small element boron prefer at the grain boundary. Fig.1a shows the hysteresis loops of the CoFeB-oxide samples with different oxide fraction. Film thickness fixed at 12 nm. With the increase of the oxide fraction, both the squareness and the coercivity were decreased. The decrease of the squareness indicates that part of CoFe grains are decoupled by the oxide grain boundary, and switch gradually. And the decrease of the film coercivity shows that the grain size of the CoFe decreases. Film became superparamagnetic when oxide fraction is higher than 40% (insert of fig.1 a). The hybrid free layer with different NCC layer thickness was studied (fig.1b)(oxide fraction fixed at 30 at%). With increase of the NCC layer thickness from 1nm to 3 nm, the saturation magnetization keeps constant, and its coercivity increases slowly. The insert of fig.1b shows the superparamagnetic behaviour of a single CoFeB-oxide layer with 3 nm thickness.

The sample with full MTJ structure was deposited by sputtering method. The film structure is: SiO₂/Bottom electrode/IrMn/CoFe/Ru/CoFeB/MgO/ composite free layer/top electrode. The composite free layer is: CoFeB 2nm /CoFeB-oxide30at% (NCC layer)3nm/CoFeB 1nm. The sample was patterned by e-beam lithography into 200 nm*600 nm with different shape (bar and ellipse) in order to observe the intermediate states. For ellipse shape sample, the hysteresis loop and the current-induced switching are shown in fig2 a-c. When the bias field changed from the switching field (H_{sw}) to the offset field, J_c increases and reaches to 5×10^6 A/cm² when the bias field equals to the offset field. From AP to P state switch, an intermediate state (IM) is observed in both field-driven and current-driven switching. Fig2c shows the CIMS switching from P to AP state. Different from the AP to P switch, the switching is sharp and there is no intermediate state. The final AP state is confirmed by measuring the resistance using a small current (2×10^{-5} A) at zero field after each scan. The bar shape sample also has an intermediate state (fig.2d-f). Fig.2e and 2f show the minor loops of current-driven switching. IM state also exists when applying a negative current, which is different from the ellipse shape sample. As expected for MTJ with large size, there may be multidomain structure in its free layer. However, this cannot explain the distinct and reversible intermediate states observed in this work. The repeatable and distinct intermediate states may come from the pinning sites induced by the granular type nano-current-channel layer. Detailed discussion will be addressed in the full paper.

Spin transfer switching in magnetic tunnel junctions with several compositions of the free layer.

D. Watanabe¹, M. Oogane¹, Y. Ando¹, T. Miyazaki²

Current induced magnetization switching has a potential as a key technology for a writing scheme in high-density MRAM. To achieve it, the critical current for the switching should be reduced from the value reported recently [1] because applying current is restricted by a peripheral circuit in MRAM. Theoretical predictions [2] have suggested that critical current was proportional to the magnetic parameter $\alpha M_s^2/g$, where α , M_s , g were respectively damping constant, saturation magnetization, and spin-transfer efficiency which was described as $g = P/(1+P^2\cos\theta)$ (P : spin polarization) in MTJ [3]. To utilize it as a lead for reducing critical current, it is important that the relation between the magnetic parameters of small ferromagnet and critical current is confirmed experimentally.

Magnetic tunnel junctions (MTJs) were prepared using UHV sputtering system with the structure of buffer/IrMn/CoFe/Ru/CoFeB/MgO/CoFeB/Ta/capping on an oxidized Si wafer. The first and second CoFeB correspond to pinned and free layer, respectively. The free layer has a thickness of 2 nm and compositions altered as $(\text{Co}_{50}\text{Fe}_{50})_{100-x}\text{B}_x$ ($x = 20, 25, 30$). The films were fabricated into a size of about $100 \times 200 \text{ nm}^2$ by electron beam lithography and ion milling. Tunnel magnetoresistance (TMR) loops with sweeping magnetic field and current were obtained using 4-probe lock-in amplifier method. Applied current was pulsed with a duration ranging from 10 μs to 100 ms and defined flowing from bottom to top electrode as a positive. The α value of each free layer in the TMR multilayer was evaluated using FMR method by which the intrinsic value without the effect from magnetic inhomogeneity can be obtained [4]. The M_s was measured by VSM.

Fig. 1 shows the TMR ratios as a function of resistance area product (RA) in each MTJ with $x = 20, 25, 30$ after annealing at 325°C under a magnetic field of 1 T. The TMR ratios with $x = 20$ were 100-120% at around $RA = 10 \Omega\mu\text{m}^2$. However, the TMR ratios were reduced rapidly with increasing boron density of the free layer because the annealing temperature was not enough to crystallize the CoFeB, which was necessary for high TMR ratio in MgO-based MTJs. The inset in Fig. 1 shows typical TMR loops with magnetic field and current scan, respectively, in the MTJ with $x = 20$. Good agreement in the resistances between two magnetization states is confirmed. The inset in Fig. 2 shows the dependence of the critical current on the current pulse width. Solid lines are the fitting result using thermal activation model which defined critical current as $I_c^\pm = I_{c0}^\pm [1 - k_B T / E \ln(\tau_p / \tau_0)]$ [5], where k_B , E , τ_p , τ_0 are Boltzmann constant, activation energy, pulse width, and inverse of attempted frequency ($\sim 10^9$ GHz), respectively. The symbol + (–) means a magnetization switching from anti-parallel(AP) to parallel(P) (P to AP) state. The critical current density $J_{c0} = (I_{c0}^+ - I_{c0}^-)/2A$ (A : junction area) and thermal stability $E/k_B T$ could be obtained from the fitting. These parameters are comparable for different MTJs and considered as an indicator for devices. From the fitting to the inset in Fig. 2, both $J_{c0} = 6.7 \times 10^6 \text{ A/cm}^2$ and $E/k_B T = 33.2$ were estimated. The J_{c0} observed in each MTJs and the parameter $\alpha M_s^2/g$ are plotted in the vertical and horizontal axis of Fig. 2, respectively. In the calculation of $\alpha M_s^2/g$, experimentally obtained values, $\alpha = 0.014, 0.014, 0.017$ and $M_s = 1370, 1150, 950 \text{ emu/cc}$, in the free layer with $x = 20, 25, 30$ were used, respectively. The line in Fig. 2 has the slope of $4\pi ed/h$ which is the proportionality coefficient in the theory, where d is set to 2 nm as the free-layer thickness. Because the measured values were in

nearly agreement with theoretical line in Fig. 2, the theoretical relation between the J_{c0} and the magnetic parameter $\alpha M_s^2/g$ was confirmed experimentally.

Spin Torque Induced Magnetization Switching Variations.

X. Wang, W. Zhu, M. Siegert, D. Dimitrov
Seagate Technology, Bloomington, MN

Fast magnetization switching under spin torque current excitation and sufficient thermal stability at room temperature are two main design criteria for spin torque magnetic random access memory (MRAM). When characterizing spin torque induced magnetization switching, both the averaged switching behavior and the switching variations are critical. Here spin torque induced magnetization switching variations are studied based upon experimental measurement and theoretical modeling. The study covers a wide time range, from the short time dynamic switching (10 nanosecond) to the long time thermal switching (0.1 sec). The modeling and the experimental measurements provide valuable information and tools for design tradeoffs between current switching magnitude, switching variations, switching speed and thermal stability.

Square wave polarized current pulses with different pulse durations and amplitudes are used to switch free layers of the magnetic tunneling junctions. Figure 1a shows the measured switching current variations as a function of the pulse width. As the pulse width decreases, mean switching current increases. The switching current standard deviation remains almost constant for long pulse width and starts to increase when the switching time decreases to certain threshold. Figure 1b shows the measured switching time standard deviation versus the measured mean switching time for constant current amplitude. It is found that the switching time variation is almost the same as the mean switching time for long time switching process and the ratio of the switching time variation to the mean switching time decreases for short time switching process. When standard deviations of the switching current or time are normalized to their means, the coefficients of variation of the switching current or time are obtained. Interesting enough, experimental data shows the coefficient of variation of the switching time decreases while the coefficient of variation of the switching current could increase as the current pulse width scales down from the long time thermal reversal region to the short time dynamic reversal region.

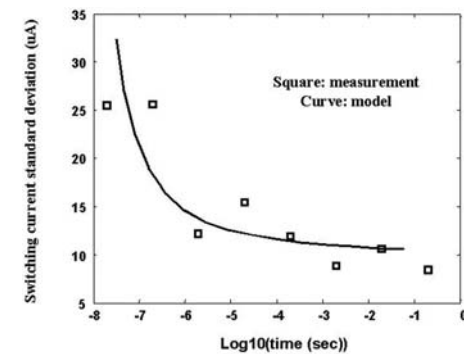

We have solved stochastic Landau-Lifshitz-Gilbert (LLG) equation with spin torque term at room to describe the switching time mean/variations and switching current mean/variations [1]. Figure 2 shows an example of the modeled coefficient of variation and standard deviation of variation of the switching current and the switching time. The model results show the same trend as that of the experimental measurements in Figure 1. In this comparison, only trend matters because the model parameters have not been calibrated to experimental measurement condition. Figure 3 shows an example of model data calibration on the switching current standard deviation versus the pulse width. In this presentation, we will show detailed model data calibrations on spin torque induced switching variations for the whole time range. We will explain the physics for the this different scaling behavior of switching current variation and switching time variation as time scales down from second to nanosecond region.

Spin-torque driven ferromagnetic resonance of Co/Ni synthetic layers in spin valves.

W. Chen¹, G. de Loubens¹, J. L. Beaujour¹, A. D. Kent¹, J. Z. Sun²

1. Physics, New York University, New York, NY; 2. IBM T. J. Watson Research Center, IBM, Yorktown Heights, NY

Spin-torque-driven ferromagnetic resonance (ST-FMR) in nanostructured magnetic junctions has recently been observed both in magnetic tunnel junctions and in spin-valves [1, 2]. It is a quantitative tool for measuring the magnetic anisotropy and damping of magnetic layers in confined nanojunctions [3]. It also enables measurement of spin transfer torques [4]. Using this method, we have measured the anisotropy and damping of Co/Ni synthetic layers in spin-valves [5]. We also measured the torque acting on this layer. Experiments were conducted on $[[t \text{ nm Co } 2t \text{ nm Ni}] \times 1.2/t] 10 \text{ nm Cu} | 12 \text{ nm Co} |$ layer structures patterned to $\sim 50 \text{ nm}$ lateral dimensions using a nanostencil process. We varied the Co thickness t from 0.1 to 0.4, tuning the magnitude of the Co/Ni synthetic layer's net anisotropy, while the total magnetic moment and thickness of the free layer were kept nearly constant. Field swept ST-FMR measurements were conducted with a magnetic field applied perpendicular to the layer surface. A microwave current was fed into the spin valve junctions at a fixed frequency between 1 and 20 GHz. The field-swept resonance lines were measured as a function of microwave frequency, power and dc current bias. In a low rf power, linear response regime, magnetic anisotropy constants and damping parameters were determined. These results were compared with those obtained from same-stack extended films measured using conventional rf field driven FMR. The layers confined in spin valves have a lower resonance field as shown in Fig. 1(a), which is associated with the effect of both dipolar fields acting on the Co/Ni layer emanating from other magnetic layers in the device, and finite size effects on the spin wave spectrum. The layers confined in spin valves also have a narrower resonance linewidth, and approximately the same linewidth vs frequency slope, as shown in Fig. 1(b), implying the same damping parameter and a lower magnetic inhomogeneity in the confined structure.

The high-field spin-torque instability threshold currents were determined from measurements of the resonance linewidth vs dc bias (Fig. 2), and the results are in accord with the ones obtained from I-V measurements. The magnitude of spin transfer torque was estimated from both the zero dc bias resonance line and from the change of the resonance linewidth with dc current. These two sets of results are in agreement with each other, and consistent with a sinusoidal dependence of the torque on the angle between the Co and Co/Ni synthetic layer magnetization for $60^\circ \sim 80^\circ$. At higher rf power, asymmetric lineshapes were observed, which we associate with large angle precessional dynamics of the free layer.

Spin torque transfer in deep submicron annular cpp-gmr devices.

M. T. Moneck, X. Zhu, J. Zhu

Electrical & Computer Engineering, Carnegie Mellon University, Pittsburgh, PA

The ability of a spin polarized current to impart a torque on a magnetic film through spin momentum transfer has been the subject of much interest in recent years. The majority of experimental spin transfer research has focused on magnetic point contacts or nanopillars with a linear in-plane magnetization mode [1],[2]. Annular current-perpendicular-to-plane (CPP) multilayer giant-magnetoresistive (GMR) devices offer many advantages such as the absence of magnetic stray field and robust magnetic switching [3],[4]. In this paper, we present an experimental demonstration of the spin torque transfer effect in annular CPP-GMR devices at deep submicron dimensions when switched by a vertically injected current.

Each CPP-GMR annular element, shown schematically in Fig. 1(a) and experimentally in Fig. 1(b), is patterned to a 600 nm outer diameter and 200 nm inner diameter from a sputter deposited film stack with the following structure: Ta (50 Å)/ Cu (500 Å)/ Ta (30 Å)/ NiFe (20 Å)/ CoFe (10 Å)/ Cu (35 Å)/ [CoFe (10 Å)/ Cu (3-5 Å)]x4/ CoFe (110 Å)/ Cu (1500 Å). In this pseudo spin-valve design, the element free layer consists of a Ni₈₁Fe₁₉/Co₉₀Fe₁₀ composite stack, and the reference layer consists of a Co₉₀Fe₁₀ film containing nano-Cu insertions for an increase in the CPP-GMR effect [5]. Both readback and switching of the reference and free layer circular orientation is performed by vertically injecting current through the stack, using the four-point probe test structure shown in the inset of Fig. 1(b), where each test structure is fabricated by a combination of electron beam lithography, optical lithography, and ion milling [5].

The switching of the annular CPP-GMR devices occurs through two mechanisms, one being the Amperean field generated from the injected current and the other being spin momentum transfer. Fig. 2 represents two magnetoresistance curves taken for the annular CPP-GMR elements. Each curve was produced by sweeping a DC current to switch the circular magnetization of the free layer between parallel and anti-parallel states while maintaining the state of the reference layer. For the black curve, the reference layer was clockwise, while the counterclockwise orientation was used for the gray curve. The large disparity between the switching currents of the two curves is a direct result of spin transfer. The major contribution to the switching is the Amperean field, which is independent of the magnetization chirality of the reference layer. If acting under this field alone, the device would switch symmetrically at approximately 13 mA, corresponding to a current density of $5.2 \times 10^6 \text{ A/cm}^2$. Conversely, spin transfer does depend on the magnetization chirality of the reference layer and acts to either assist the Amperean field or work against it. In the case where the reference layer is magnetized counterclockwise, the spin transfer torque acts to assist the Amperean field, thus lowering the switching current by 1.3-3.2 mA, depending on the direction of the injected current. For a reference layer magnetized clockwise, the spin transfer torque acts against the Amperean field by the same amount. In both cases, the spin transfer effect clearly has a measurable impact on the switching properties.

Effective description of planar spin-transfer devices.

Y. Bazaliy

1. Department of Physics and Astronomy, University of South Carolina, Columbia, SC; 2. Institute of Magnetism, National Academy of Science, Kyiv, Ukraine

Spin-polarized currents are able to change the magnetic configuration of nanostructures through the spin-transfer effect proposed more than a decade ago [1,2]. Intensive research is currently directed at understanding the basic physics of this non-equilibrium interaction and designing magnetic nanodevices with all-electric control. In those devices spin transfer torques play a key role creating dynamic regimes that are not present in conventional magnetic systems. Unfortunately full dynamic study is not straightforward even for simple spin transfer devices due to the nonlinearity of the Landau-Lifshitz-Gilbert (LLG) equation governing the magnetization motion. A simple device consists of a dynamic magnet (free layer) influenced by the current coming from a stationary spin polarizer (fixed layer) [2,3]. When magnetic anisotropy of the free layer is an easy axis parallel to the spin polarizer direction, the problem can be solved exactly [2,4] But if in addition the easy plane anisotropy of actual devices [5] is accounted for, and/or the polarizer direction is different, the calculations become much more involved. As the anisotropy gets more complicated, additional dynamic features appear: “canted states” [4,6], multiple precession states [6], “magnetic fan” regimes [6], etc. Experimentally, the easy plane anisotropy energy is usually much larger than the easy axis energy, i.e., the system is in the regime of a planar spintronic device [7] (Fig. 1). Fortunately, the limit of dominating easy plane energy is characterized by a simplification of the dynamic equations [8], which mathematically arises from the existence of a small parameter: the ratio of the energy modulation within the plane to the easy plane energy. Physically, the magnetization moves with little deviations from the easy plane and thus can be well described by the in-plane angle governed by an effective planar equation.

In Ref [8] effective equation was derived in the absence of spin-transfer torques. In this work we derive the effective planar equation that takes into account spin transfer torques in general form [9]. Importantly, effective equation has the form of Newton’s equation of motion for an effective particle in external potential with a variable viscous friction coefficient. The advantage of such a description is that the motion of the effective particle can be qualitatively understood by applying the usual energy conservation and dissipation arguments. In the absence of current, the effective friction turns out to be a positive constant, so after an initial transient motion the system always ends up in one of the minima of the magnetic energy. However, when current is present, effective friction and energy are modified. Such a modification reflects the physical possibility of extracting energy from the current source, and leads to the emergence of the qualitatively new dynamic regimes: jumps between the minima which correspond to current induced switching events, and persistent oscillations which correspond to the precession states induced by spin-transfer torques. The power of the planar approach is demonstrated in two cases. First, we analytically calculate the boundaries between different precession cycles [11,6] in the nanopillar device. So far, those boundaries were studied only numerically [6]. Our analytical calculation based on the effective particle analogy is surprisingly simple [10] Second, we study current-induced switching in a spin-flip transistor [12] and find a new equilibrium stabilized by the current [9]. This stabilization is highly counterintuitive in the following sense: the direction found in Ref. [9] is not stabilized by the anisotropy torques (it is a saddle point) and the added spin transfer torque repels the system from this direction as well. The phenomenon is dubbed as stabilization by repulsion. Even though the conclusion is counterintuitive, it is completely confirmed by the no-approximation calculations and

numeric modeling. We show that stabilization by repulsion is closely connected to the dissipation in the system and happens in the overdamped regime already noticed in the conventional case without the spin-transfer torques [8].

Magnetization reversal driven by spin-injection : a mesoscopic spin transfer effect.

J. Wegrowe

LSI, Ecole Polytechnique, Palaiseau, France

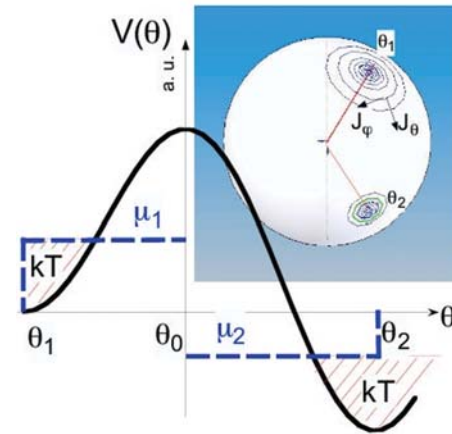

A mesoscopic description of spin-transfer effect is proposed, based uniquely on the spin-injection mechanism occurring at the junction with a ferromagnet. The effect of spin-injection is to modify locally, in the ferromagnetic configuration space, the density of magnetic moments. The corresponding gradient leads to a current-dependent diffusion process of the magnetization. In order to describe this effect, the dynamics of the magnetization of a ferromagnetic single domain is reconsidered in the framework of the thermokinetic theory of mesoscopic systems.

Assuming an Onsager cross-coefficient that couples the currents, it is shown that spin-dependent electric transport leads to a correction of the Landau-Lifshitz-Gilbert equation of the ferromagnetic order parameter with supplementary diffusion terms. The consequence of spin-injection in terms of activation process of the ferromagnet is deduced, and the expressions of the effective energy barrier and of the critical current are derived. Magnetic fluctuations are also calculated: the correction to the fluctuations due to spin-injection is similar to that obtained for the correction of the activation process. These predictions are consistent with the measurements of spin-transfer obtained in the activation regime and for ferromagnetic resonance under spin-injection.

The motivation for a classical mesoscopic analysis was the need to account for the following highly specific properties observed in spin-transfer experiments that can hardly be accounted for in direct microscopic approaches [1]. First, in single domain

ferromagnets, the reversible part of the hysteresis loop is not significantly modified under current injection, while the irreversible jump is drastically modified [1]. Second, the amplitude of spin-transfer is proportional to the giant magnetoresistance and to the amplitude of the current. Third, the Néel-Brown activation law is still valid under current injection, with a correction of the barrier height that is quasi-symmetric under both the permutation of the magnetic configuration (parallel to anti-parallel and inversely) and the change of the direction of the current. "Quasi"-symmetric means here that a quantitative shift (a factor 2 to 4 in general) is systematically observed in the amplitude of spin transfer for both transitions in spin-valve structures. Fourth, this last quasi-symmetry is also observed in the context of ferromagnetic resonance under current injection close to the equilibrium states (i.e. with an weak spin-injection).

The configuration space of the ferromagnetic order parameter is represented by a sphere of radius unity. The double well shown is a projection over the plane that contains the two equilibrium states at θ_1 and θ_2 , and the top of the barrier at θ_0 . The step approximation for the chemical potential is plotted with the thermal fluctuations sketched by the dashed area around the two minima.

Illustration of the spin-accumulation occurring in a nanoscopic ferromagnetic layer with its two non-ferromagnetic contacts: the profile of the electrochemical potential difference $\Delta\mu$ is plotted as a function the spatial coordinate z .

Current-Induced Magnetic Domain Wall Motion at Low Current Density via Perpendicular Anisotropy.

The current-induced motion of magnetic domain wall (DW) carries great potentials for applications such as nano-scaled logic and memory devices. To achieve this goal, a large reduction in the threshold current density J_c for the domain wall motion is highly desired. Here we show that by introducing and properly exploiting the perpendicular magnetic anisotropy (PMA), J_c can be reduced by one or even two orders of magnitude in experimentally accessible parameter regimes. The PMA changes the easy axis of the magnetization from the wire direction to the direction perpendicular to the wire plane. For a defect-free magnetic nanowire, the theory predicts [1] that J_c is related to adverse effects suppressing the DW motion such as anisotropy K_d associated with the tilting of the DW. Analyzing the DW motion following the Thiele's approaches [2], we found that the change of the easy axis significantly influences K_d so that the K_d of the PMA wire is considerably different from that of the in-plane anisotropy (IMA) wire, which leads to the reduction of J_c . We calculated analytically K_d as a function of the wire width w for a given wire thickness t . By tuning w properly, K_d can be suppressed to arbitrarily small values, which in turn reduces J_c considerably. This tuning of w for the PMA wire is much easier than the IMA wire since K_d for the PMA wire depends on the ratio w/l while K_d for the IMA wire depends on the ratio w/t where l is the DW width. The analytic result is in good agreement with the prediction of our micromagnetic simulations of the LLG equation with spin transfer torque terms. We also performed the micromagnetic simulation to see the DW motion in realistic nanowire with a single notch, edge roughness, and/or PMA fluctuations. Despite of these imperfections, we found that the J_c of the PMA wire with experimentally reasonable parameters is also much smaller than the IMA wire because of the difference in the anisotropy K_d . Especially, the resulting J_c is insensitive to domain wall pinning forces related to the imperfections and also to the non-adiabaticity, both of which are hard to control in experiments. These results suggest that the PMA wire is useful for DW-based nano-scale magnetoelectric devices and also allows probing fundamental aspects of spin and magnetization dynamics.

The feasibility of the manipulation of magnetic domains and domain walls by spin-polarized current injection is of great scientific interest and has large potential for applications. Controlled manipulation of current-induced domain wall motion is crucial for any device based on this effect. This requires an in-depth understanding of the underlying theory.

The influence of spin-polarized current on the magnetization can be described theoretically by an adiabatic and a non-adiabatic term added to the Landau-Lifshitz-Gilbert equation of motion [1,2]. Here especially the magnitude of the non-adiabatic term, the so called non-adiabaticity constant β is currently much under debate and for controlled domain wall motion a detailed knowledge of this term is necessary. In particular the relation between β and the damping constant α is debated. While some predict that $\beta=\alpha$ [3,4] other found that in general $\beta\neq\alpha$ [5,6].

Thus experiments addressing this topic are of utmost importance. Current-induced domain wall motion has been observed by a number of groups using different techniques [7-11], but so far detailed statements concerning β could not be deduced.

We present new results on the interaction of spin-polarized currents with the spin configuration studied by direct imaging using X-ray photoemission electron microscopy.

In a magnetic wire, two domain wall configurations prevail: the vortex wall (VW) and the transverse wall (TW). VWs are characterized by the magnetization curling in-plane around the vortex core and the polarity of the vortex core. The sense of rotation can be either clockwise or counter-clockwise. In a TW the magnetization rotates in-plane by 180° similar to a Néel wall.

In 1000 nm wide and 28 nm thick Permalloy wires, VWs are energetically more favorable, due to their lower stray field. In these wires we observed not only current-induced domain wall motion but also current-induced DW transformations [12]. Due to the spin torque effect additional vortices are created, so that a single VW is transformed to a double VW. But not only DW nucleations, but also DW annihilations were observed.

This indicates that the spin-polarized current not only displaces DWs but also has a profound influence on the internal structure of the DW. To further study this effect magnetic wires where VWs as well as TW can coexist were examined [13]. In these wires periodic transformations between the two DW types are predicted to occur under current injection.

We studied current-induced domain wall motion in 1500 nm wide and 8 nm thick Permalloy wires and observed propagation and transformation of the DWs after current pulse injection.

In Fig. 1 an XMCD image sequence of such transformations is shown. The bottom row shows results from a corresponding simulation [14]. The initial TW (a) is transformed to a clockwise VW (b) by a 25 μ s long 10^{12} A/m² strong current pulse. (c) A further injection results in a TW but with opposite transverse component compared to the initial TW. (d) The next injection yields an off-center VW. (e) Subsequent injection results again in a VW with same sense of rotation as in (b) and (d). To exclude thermal effects as a possible cause for these transformations we can make use of the fact that for a given initial spin structure the spin torque predicts transformations to VWs with always the same sense of rotation, whereas for thermally induced transformations both kind of VWs should occur equally often. Since we only observe transformations to clockwise VWs, this clearly rules out

thermal effects and fits to theoretical predictions under the assumption that the non-adiabaticity parameter β does not equal the damping constant α [15].

Furthermore we observe current-induced vortex core displacements in magnetic disks. It is shown that the direction of the vortex core displacement depends on the vortex core polarity, but not on the sense of rotation in agreement with theory [16].

This also shows the fundamental difference of current- and field-induced displacements, where the direction depends solely on the sense of rotation.

Dynamics of domain walls in soft magnetic nanostripes: soliton approach.

K. Guslienko, J. Lee, S. Kim

Research Center for Spin Dynamics & Spin-Wave Devices and Nanospintronics Laboratory,
Materials Science & Eng. Dept., Seoul National University, Seoul, South Korea

Recently the motion of domain walls (DWs) driven by magnetic field or spin polarized current in magnetic nanostripes became of considerable interest. One of the central issues is to understand DW motions under an applied magnetic field (H) stronger than a critical field (the Walker field), H_w . When H is applied to “head-to-head” (“tail-to tail”) DW in nanostripes, the DW propagates along (against) \mathbf{H} direction increasing its velocity with increasing H below H_w . But for $H > H_w$, the average velocity v decreases considerably [1] and DW oscillations occur [2].

In this talk, we report a soliton approach to the description of moving DWs in nanostripes that reveal oscillations in high- H regime or a steady movement in low- H regime. Our model explains DW dynamics by the motions of a limited number of magnetic topological solitons [vortices (V) and antivortices (AV)], via their emission, gyrotropic motion and absorption. The vortex or antivortex walls (VW or AVW) contain a single V(AV) and some solitons at the stripe edges [3]. V and AV bear topological charges q related to their cores and have non-zero gyrovectors [4]. The gyrovectors result in V(AV) gyrotropic motion determined by the magnetic energy W . The transverse walls (TW) correspond to half-integer ($q=\pm 1/2$) topological solitons located on the edges [3]. The VW(AVW) have also half-integer q similar to ones in the TW. The emission of V(AV) changes the edge soliton charges from $+1/2(-1/2)$ to $-1/2(+1/2)$. The relatively slow gyromotions lead to essential decrease of v due to V(AV) motions against the \mathbf{H} direction.

To find the soliton trajectories and traveling times, we use the Landau-Lifshitz equation of motion (LLG) in the form of Thiele's equation of motion of the soliton core position $\mathbf{X}=(X,Y)$ in the stripe x - y plane [4]. We use the energy decomposition $W(\mathbf{X})=\kappa Y^2/2-\lambda \mathbf{X}\mathbf{H}+\mu z[\mathbf{X}\times\mathbf{H}]$, where the first term describes W variation in the transverse direction of nanostripe (κ is the stiffness coefficient), the 2nd and 3rd terms describe the motion of DW as a whole and interaction of V(AV) with \mathbf{H} [4]. $\lambda=2M_s w L$, $\mu\approx 2M_s w L$ ($\mu\approx 0$) for V(AV), L and w are the nanostripe thickness and width.

By solving the equations of motion for X and Y , the trajectories of V(AV) are found. For a steady motion perpendicularly to the nanostripe length, a quasi-1D solution $dX/dt=D_{xx}^{-1}\partial W/\partial X$ exists, which corresponds to the viscous DW motion [5]. This motion is stable in low fields and occurs only for TW or VW in infinitely long stripes. The components $D_{\alpha\beta}$ of the damping tensor are calculated for TW(VW) and the TW(V) velocity can be written as $dX/dt=\lambda H/|D_{xx}|$. The moving V experiences a force due to the field H , which pushes the vortex perpendicularly to the stripe length. The equation of motion for Y (VW) has a stationary point Y_0 . The field when Y_0 reaches the stripe edge is the critical field H_w and means beginning of oscillations of the DW internal structure. Estimation yields $H_w=\alpha 2\pi M_s L/w$. I.e., the critical field in nanostripes ($L/w\ll 1$) is essentially reduced comparing to bulk 1D case [5]. The DW velocity reaches the maximum value $v_m=2\gamma M_s L$ for nanostripe that is essentially smaller than the Walker result [5]. The explicit trajectories of the V(AV) gyrotropic motions within the VW(AVW) for $H>H_w$ between their emission and absorption at the nanostripe edges are calculated. They are quite complicated, but for the LLG damping $\alpha\ll 1$ we get the simple parabolas. The values of κ determining their slope are different for V(AV) and were calculated numerically. The traveling time t_s of V(AV) between the stripe edges is $t_s=\pi\gamma/H$ within the limit $\alpha\ll 1$ (or $H\gg H_w$). It does not depend on the nanostripe sizes L , w and intrinsic material parameters M_s , α . The traveling time t_{TW} of the edge solitons between the absorption and emission of V(AV) can be neglected comparing to t_s . The period of the DW oscillations is $\approx 2t_s$ and the eigen-

frequency is the Larmor frequency, $\omega=\gamma H$. To calculate v at $H>H_w$, we average the DW velocity over the oscillation period and get $v\approx v_{TW}t_{TW}/t_s$. This equation describes a considerable v drop just above H_w , $v\approx(0.1\sqrt{0.2})v_m$, which was observed experimentally in nanostripes [1].

We also conducted micromagnetic simulations [6] assuming rectangular permalloy nanostripes with $L=10$ nm, $w=60\sqrt{240}$ nm. The simulated DW velocity v increases linearly with increasing H ($H<H_w$). Just above H_w , v decreases remarkably [1,3]. Above H_w , $v(H)$ is constant, and the oscillatory motions of DWs appear [3]. The dependence of $t_s=\pi\gamma/H$ for VW and AVW is in good agreement with simulations. We confirmed that t_{TW} is small (<1 ns) and in high fields only VW and AVW represent the DW oscillations until a chaotic regime revealing multi-soliton states. The simulated V(AV) core trajectories were well fitted to the parabolic equations $X(Y)$ and $\kappa>0$ ($\kappa<0$) for the VW(AVW) were calculated. Recent experimental observations of DW motion in the nanostripes [1,2] can be explained by our model.

1. Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom; 2. Electrical and Computer Engineering, National University Singapore, Singapore, Singapore

Domain walls (DWs) in ferromagnetic nanowires are currently the focus of intense research activity due to their potential applications in spintronic devices [1]. A greater understanding of the fundamental properties and behaviour of DWs is required, however, before such devices can be realised. The nanostructures investigated here are shown schematically in fig. 1a. They were fabricated by electron beam lithography in thermally evaporated $\text{Ni}_{80}\text{Fe}_{20}$. For wires of 350 nm width and 20 nm thickness, the favoured head-to-head wall structure is a vortex DW (VDW) according to the DW structure phase diagram [2]. Application of a field approximately perpendicular to the wire resulted in the nucleation of a DW between the anti-notch and the diamond end-shape. Thereafter DWs were driven along the wire with a parallel field, the direction of the field being chosen to drive the wall towards the anti-notch. Here we explore the effect of triangular anti-notches of constant width, 400 nm, and heights varying between 100-675 nm.

Characterisation of the magnetic behaviour was carried out using the Fresnel mode of Lorentz microscopy [3]. Magnetic contrast arises at the positions of DWs and also at the edges of the structure where M lies parallel to the edges. Regions of increased or decreased intensity appear superimposed on the defocused image of the nanowire. The thick dark fringe along the upper edge of the wire, indicated by A in fig. 1b, indicates that this section of the wire is oppositely magnetised to the wider end region at B where the dark fringe is along the lower edge. The magnetisation configuration is illustrated in fig. 1a. The appearance of the vortex core, white or black, depends directly on the sense of rotation of the magnetisation around it; here a clockwise (cw) VDW is shown. The anti-notch gradient α , for an anti-notch 100 nm high is 27° , which means that the magnetisation only has to deviate modestly from the direction in the main body of the wire to align with the gentle slope of the anti-notch. Figure 2a shows that under only a small applied field the VDW enters the anti-notch to form the configuration shown in fig. 2b, suggesting that the anti-notch acts as a potential well.

For an anti-notch of height 675 nm, however, the anti-notch acts as a potential barrier and the clockwise VDW is pinned just in front of it, fig. 2c. In this case, α is 59° and the magnetisation in the notch lies approximately perpendicular to the wire, as seen from the thick dark fringe at positions C and D in fig. 2c. Thus this anti-notch acts as a potential barrier for a cw VDW, the magnetisation distribution being as shown schematically in fig. 2d. Not surprisingly different behaviour is observed in the two cases as the field is increased. For the shallower anti-notch, the VDW distorts and it extends into the far side of the wire, fig. 2e. Simultaneously, the vortex core is forced further into the apex of the anti-notch prior to depinning. Reversal occurs at 67 Oe. In the second case, the VDW is never stable in the anti-notch, reversal occurring abruptly at a field ≈ 75 Oe.

Somewhat different behaviour is observed if the chirality of the VDW is changed. Fig. 3a shows that the ccw VDW is pinned in the 100 nm anti-notch in a similar manner to the cw VDW. However, the ccw VDW interacts with the 675 nm anti-notch in an entirely different manner, figs. 3b and c. The magnetisation of the leading domain has a component pointing perpendicularly upwards and hence in a similar sense to the magnetisation in the anti-notch. Thus the DW enters the anti-notch suggesting that for a ccw VDW the anti-notch acts as a potential well for both low and high values of α . Under increasing applied fields both DW structures distort and extend into the wire, figs. 3d and e, before depinning at fields of 72 and 76 Oe respectively. In summary a 100 nm high anti-

notch attracts VDWs of both chiralities whilst the behaviour of a 675 nm high anti-notch depends on the chirality of the incoming VDW.

Domain wall pinning mechanism in ferromagnetic nanowires.

*D. Petit, A. Jausovec, E. Lewis, H. T. Zeng, L. O'Brien, D. Read, R. P. Cowburn
Physics, Imperial College London, London, United Kingdom*

The chirality dependent [1] interaction mechanism between transverse domain walls (TDWs) in Permalloy nanowires and artificially patterned traps is studied using high sensitivity spatially resolved Magneto Optical Kerr Effect measurements. The DWs are created at the C-shaped end of the structures using external magnetic fields. The pinning from T shaped traps is investigated, where a DW travelling in the horizontal arm is pinned by the vertical arm (see Fig. 1). The chirality of the incoming DW and the micromagnetic configuration in the trap are independently controlled using external magnetic fields and by placing the transverse arm either inside the curvature of the C (“In”), or outside (“Out”), allowing all four different DW/trap configurations to be studied. The pinning strength (Fig. 2) as well as the potential energy profile created by the traps are measured for all cases, and the roles of the different DW characteristic parameters, such as the sign of the DW charge, the DW core orientation and the magnetic charge distribution within the DW, are separately assessed. It is found that whether or not the core of the DW is aligned with the transverse arm of the T affects the shape of the main potential experienced by the DW, whereas the pinning strength strongly depends on which side of the V-shaped TDW interacts with the trap. These effects are discussed in terms of the magnetostatic interaction between the DW and the junction. We also present results of numerical simulations which are in excellent qualitative agreement with the experiments. Finally, a chirality analysing and filtering mechanism is experimentally demonstrated.

The behaviour of magnetic domain walls (DWs) in nanowires has attracted much attention with potential applications including spintronic logic [1] and memory devices [2]. In these devices information is encoded in the magnetic states of domains in lithographically patterned nanowires. Quantitative correlation between the depinning field and pinning site geometry is highly relevant to both field and spin-polarised current induced domain wall behaviour and may ultimately lead to optimising the control and efficiency of these devices.

Experiment

Two samples of permalloy nanowires of the same nominal dimensions were fabricated using different lithographic techniques. Each nanowire was ten nanometres thick and contained a micron-scale nucleation pad on one end [3] and was sharply tapered at the other [4]. Wire widths ranged from 600 nm to 200 nm, with each structure containing a single pinning site along one side of the wire. The pinning potential of two different pinning site geometries was investigated, including triangular and rectangular shaped sites in the notch and prominence configuration. The first set of samples was prepared using electron beam lithography, thermal evaporation and 'lift-off' techniques. Spatially resolved magnetisation analysis was performed using a high sensitivity focused magneto-optic Kerr effect (MOKE) magnetometer. Placing the laser spot over pad/wire junctions and after the pinning sites allowed for the study of DW injection and also to quantify the pinning potential as a function of site geometry. The second set of nanowires was prepared by thermally evaporating films onto a silicon nitride membrane which was then directly patterned using focussed ion beam (FIB) milling. DW pinning behaviour was imaged using Lorentz transmission electron microscopy (TEM). The spin structure of pinned DWs was also investigated using the OOMMF micromagnetic code [5].

Results

Fig. 1 shows the average DW injection fields for different wires of the same nominal dimensions as a function of wire width. As the wire width decreases the field required to inject a DW increases significantly as is consistent with the pad/wire junction forming a symmetrical potential well. For narrow wire widths there is a large spread in measured injection fields; this suggests such widths can support metastable DW flavours since these dimensions are close to the transverse wall (TW)-vortex wall (VW) phase transition line [6]. OOMMF micromagnetic simulations support this and suggest that an extreme asymmetric TW state is stable beyond the regime obtained by Nakatani et al.[6]. MOKE hysteresis loops reveal how the DW depinning behaviour depends strongly on the chirality of the DW, although for a fixed wire width the depinning fields are relatively insensitive to the geometry of the pinning site. Asymmetric pinning sites lift the energy degeneracy of metastable wall types, as is shown by the two distinct switching steps in Fig.2. Both TEM images and OOMMF simulations show clearly how the location at which a DW pins and the depinning field depend on the wall flavour and chirality (Figs.3 and 4), which is in good agreement with Hayashi et al [7]. A systematic investigation into the relationship between pinning site geometry and DW pinning behaviour will be presented.

The propagation field for magnetic vortex domain walls was experimentally investigated in notched nanowires of permalloy. Wires with sub-micrometer width and variable notch depth were fabricated using a lithography process. Vortex walls were nucleated and depinned by applied magnetic fields and observed with magnetic force microscopy. Numerical results were obtained by micromagnetic simulations.

Patterned ferromagnetic films have attracted increasing attention due to their promising applicability in data transfer and storage technology [1, 2]. By decreasing the thickness of a ferromagnetic structure, the magnetization is forced to align in-plane due to the shape anisotropy. In addition, by decreasing the width we obtain a wire and the magnetization is forced to align parallel with the wire axis. As a result, regions between opposite magnetizations in this wire form domain walls (DW). Typically, there are two types of domain walls; transverse and vortex domain walls. The type is determined by the geometry of the wire [3]. Vortex walls have a curling spin distribution and a small stray field that enable high density packing without interference with neighboring magnetic domains. A domain wall, trapped in the wire, can be manipulated by applied electric currents [4-8] or magnetic fields [9, 10]. In order to control the position of a magnetic wall, artificial constrictions can be introduced that reduce the number of equilibrium positions along the wire [11]. Understanding how domain walls couple with the notches under an externally applied magnetic field is important for successful manipulation of the information bits.

In this report we investigate the vortex depinning properties in nano wires with symmetrical notches on one side. The depth of the notches was varied between 20 nm and 80 nm.

The nanowires were fabricated on native silicon wafers capped with a 200 nm SiO₂ oxide and spin-coated with a negative resist. The geometry is defined by the wire width $w = 240$ nm, thickness $h = 20$ nm, notch period $l = 480$ nm and notch depth d . The patterning was done by electron-beam (EB) lithography, the deposition by EB evaporation and the lift-off process using chemical solvents. The numerical calculations were performed using the public micromagnetic OOMMF code [12] and standard parameters for permalloy; a saturation magnetization of 860 kA/m, an exchange constant of 13 pJ/m and zero magneto-crystalline anisotropy. A damping coefficient of 0.02 and a cell size $5 \text{ nm} \times 5 \text{ nm} \times h \text{ nm}$ were used. Simulations were performed on a wire segment including five notches with the trapped vortex at the central pinning site. This segment size is sufficient in the sense that the magnetostatic interference of the wire ends has a negligible effect on the propagation field.

In Figure 1, the propagation field H_p is shown for wires with a notch depth between 0 nm and 80 nm. Experimental values are taken as the average H_p from 10 different symmetrical wires. Lateral discrepancies, originating from the finite resolution in the lithography process, are indicated by the standard deviation of the data. This effect is significantly enhanced for the deeper notches. Natural defects heavily influence the pinning strength of a notch-free wire. The simulated H_p of $0.05 \text{ mT} \pm 0.05 \text{ mT}$ can be compared with the experimental value of 1 mT and results from an absence of edge roughness. The magnetization profile of the wires with $20 \leq d \leq 80$ is shown in the inset.

In conclusion, the notch geometry influences the pinning potential of a trapped vortex in the studied nano wires. Experimental and numerical results are well correlated for deeper notches, i.e. $d \geq 40$ nm, but diverge at small d due to unavoidable edge roughness in the fabricated samples.

Measuring domain wall coherence lengths using a chirality filter.

E. Lewis, D. Petit, A. Jausovec, L. O'Brien, H. Zeng, D. Read, R. Cowburn
Imperial College London, London, United Kingdom

The interaction of a magnetic domain wall (DW) with artificially-created defects in a nanostrip is important for DW-based data storage devices [1,2], in which it is required to controllably propagate DWs. Because the interaction will in general depend on the DW chirality [3] (that is, the sense of rotation of the spins across the DW), it is necessary to consider the phenomenon of Walker breakdown [4], in which the DW structure oscillates as it propagates along the strip under a field greater than the 'Walker field' H_w . In the case of a transverse DW, which is the stable structure for our nanostrips (cross-section $90 \times 7 \text{ nm}^2$), the DW core continually switches between the two transverse orientations.

We can detect these structural changes using a 'chirality filter': we fabricate L-shaped $\text{Ni}_{80}\text{Fe}_{20}$ nanostrips with a transverse arm crossing the main wire (Fig. 1 (i), (ii)) so that approaching DWs either transmit through the cross, or are blocked, depending on whether the DW core magnetisation is parallel or antiparallel to the magnetisation in the transverse arm. We create DWs of known chirality at varying distances d from the filter and use spatially-resolved MOKE (laser spot diameter $\sim 5 \mu\text{m}$) to measure the switching field of the latter part of the strip. From this, we can infer the orientation of the DW as it reaches the transverse arm: the switching field corresponding to transmission ($\sim 110 \text{ Oe}$) is roughly half that corresponding to blocking of the DW and subsequent re-nucleation of a new domain ($\sim 200 \text{ Oe}$); the propagation field is $\sim 10 \text{ Oe}$. We find that chirality reversal never occurs below a certain distance, but that at long distances, the chirality is not a well-defined function of the distance travelled (Fig. 2). We therefore characterise the motion by a 'DW coherence length', L , over which the DW chirality is effectively preserved; $L = (1.1 \pm 0.1) \mu\text{m}$ for our nanostrips.

We have also measured the field-dependence of L : we fabricate structures with varying corner radii of curvature, so that the DW de-pins and moves towards the cross at different fields. L was measured for four different fields. Analytical and numerical calculations [5] and related experiments [6] predict DW motion with a characteristic dependence of velocity and temporal oscillation frequency on the applied field. From these, a spatial $1/2$ period can be extracted, which we associate with our measured L : it is expected to decrease sharply just above H_w , and tend to a constant in large applied fields. Our measurements of L are indeed consistent with this picture, with L tending to around $0.35 \mu\text{m}$ at high fields.

In addition, we have experimentally demonstrated extension of L to metre length scales by passing the DW through a series of closely-spaced filters. We fabricate U-shaped nanostrips with many transverse arms of spacing $d = 0.25 \mu\text{m}$ (Fig. 1 (iii), (iv)). A DW is created in one corner by application of a large field pulse, followed by an oscillating horizontal field with maximum magnitude in between the transmission and nucleation fields, so that no new domains can be nucleated. In the absence of chirality reversal, the DW should continually move back and forth between the two corners of the U-shape; if the DW chirality reverses at any point, it will not be able to transmit through the crosses and the magnetisation switching of the structure will stop. We find that even after 4×10^4 cycles of the horizontal field, we still measure switching at the centre of the structure, corresponding to chirality-conserving motion of the DW over a total distance of 3.2 m .

Dynamic of depinning of a magnetic domain wall from a single defect.

F. Montaigne¹, J. Briones¹, D. Lacour¹, M. Hehn¹, M. J. Carey², J. Childress²

1. *Laboratoire de Physique des Matériaux, Nancy-University, CNRS, Vandoeuvre lès Nancy, France;* 2. *Hitachi San Jose Research Center, San Jose, CA*

The propagation and the pinning have always been key issues in magnetism. Recently, these aspects have been revisited in nanostructures. We present here results on dynamics of depinning from a single defect in a submicronic stripe.

A spin valve multilayer is patterned by electron beam lithography and Ar ion beam etching in order to create and manipulate a magnetic DW in a submicron wire 500 nm wide and 20 μm long. A nucleation pad is present on one side of the wire and a notch is positioned along the wire. Figure 1(a) shows a scanning electron microscopy (SEM) picture of a completed device. GMR measurements allow us to locate precisely the DW between the electrical contacts.

Figure 2 represents different cycles obtained by sweeping the field from 300 to -300 Oe (and back). Starting from an antiparallel configuration of magnetizations, the AP->P propagation of a domain wall from the injection pad to the notch is associated with a drop in resistance. The magnetization in the pad reverses at fields below 30 Oe but the propagation of this reversed domain is limited by the nucleation pad neck as shown by the MFM image on figure 1(b). Then, this domain is further injected in the wire at the so-called injection field and propagates to the notch. The notch acting as a pinning site stops its propagation (see MFM picture on figure 1(c)). Further increase of the field is necessary to depin the DW. At the so-called depinning field, the normalized resistance of the device drops to 0% corresponding to the parallel state. Sweeping the field backwards results in similar phenomena for P->AP propagation.

Figure 2 clearly shows that this cycle is not fully reproducible. While the domain wall is trapped at the same position (same intermediate resistance), the exact value of the injection and depinning fields varies from experiment to experiment. Histogram of the depinning fields values are represented in figure 3 for the two propagations. Significant differences in the statistics are observed. These differences are mainly due to the effect of the dipolar field originating from the hard layer (cf. ref 1). The statistic is rather simple for the AP->P propagation with two peak centred around 124 and 225 Oe. For the P->AP propagation, the distribution is much more complex. In order to get more insight in the depinning process, time resolved relaxation measurements have been performed. After injection of the domain wall in the notch, the field is kept at constant value. The time of depinning is represented in figure 3 for different field values for the AP->P propagation. It appears clearly that for field around 124 Oe, the probability of transmission saturates at 58% whereas for higher fields, there is a 58% probability of immediate depinning. The results can be explained considering that two different types of domain wall are pinned in the notch.

Direct observation of the Walker breakdown during field driven domain wall (DW) motion in Permalloy nanowires.

R. Mattheis, S. Glathe

Photonic Instrumentation, IPHT, Jena, Germany

The investigation of DW motion in soft magnetic materials started in the 1930's with the experiments of Sixtus and Tonks [1]. Forty years later Walker analysed the DW motion theoretically and found a periodic component in the forward motion of field driven DWs above a critical driving field H_w . Below this so called Walker breakdown field one finds steady state motion of the DW. Increasing the external driving field above H_w the DW movement became turbulent because of a periodic change of the DW chirality due to a nucleation and motion of an antivortex and vortex, respectively. This behaviour was found and confirmed in several simulations e.g. [2,3,4]. Up to date only one experimental study addressing the frequencies connected to the change of the DW chirality was published [5].

We investigated the DW motion in Permalloy (Py) nanostrips in terms of time resolved resistance measurements to visualise the whole process in more detail. We use additionally to the longitudinal driving field H_l a transversal field H_t to change the nucleation conditions of the DW. This gives us an additional parameter to influence the dynamics of DW motion. The 20 nm thick and 45 μm long Py nanostrip is part of a GMR stack whose resistance depends on the magnetisation direction of the Py layer with respect to the wire axis. The GMR stack was deposited by means of physical vapour deposition and patterned via photolithography and Ar ion etching under tilt.

Fig. 1 shows the DW propagation in a 150 nm wide nanostrips under different applied transversal and longitudinal driving fields H_t and H_l . The bold (thin) graph represents the temporal evolution of the voltage (velocity). In the first picture ($H_t = 19.5$ kA/m and $H_l = 5.7$ kA/m) one can clearly separate intervals of DW forward motion and intervals where the DW stops or even move backwards. This behaviour fits very well to the DW motion during the Walker breakdown process as shown by micromagnetic simulations [3,4]. Here the DW is accelerated by the external magnetic field and propagates uniformly along the nanostrips. After a certain time an antivortex and vortex respectively is nucleated at one edge of the nanostrips and moves across the nanostrips, while the chirality of the initial DW is reversed. During this antivortex (vortex) movement the initial DW stops basically with respect to the wire axis. Thus the mean velocity drops drastically if the Walker breakdown occurs. In our experiment the maximum velocity is in the range of (980 ± 200) m/s and the mean velocity is 540 m/s.

Simulations of a $20\text{nm} \times 200\text{nm} \times 4000\text{nm}$ Py layer with an edge roughness of $dr = 20$ nm have shown that the Walker breakdown is not highly periodically like in perfect wires [2,3,4]. Due to the existing edge roughness in our nanostrips the DW motion is different in every single experiment. For that reason we are not able to average over many measurements to get low-noise charts.

If the transversal field is increased the longitudinal field necessary for the nucleation of a reversed domain is decreased. For these field parameters we get only 3 clear Walker breakdown processes meanwhile the DW basically don't move with respect to the wire axis. Due to the increased transversal field the nucleation of an antivortex or vortex is partially suppressed, increasing the intervals where the DW moves. Thus the mean velocity is increased by 33 % while the maximum velocity is still (1000 ± 50) m/s. Increasing the transversal field to 21.5 kA/m the Walker breakdown is suppressed completely and we get an almost steady state motion. Now the maximum velocity is nearly equivalent to the mean velocity, which is now 990 m/s. For these 3 charts the mean velocity is increased due to the stepwise suppression of the Walker breakdown, while the maximum velocity

is nearly constant. For $H_t = 24$ kA/m and $H_l = 4.8$ kA/m the maximum velocity is increased slightly, thus we get a larger mean velocity due to the increased maximum velocity. This rise of DW velocity below the Walker breakdown although the longitudinal driving field is decreased can be explained by the broadening of the DW and the reduction of the DW angle [6].

In conclusion we are able to verify the Walker breakdown process in single measurements. Additionally we can tune the DW movement around the initiation of the Walker breakdown due to an applied transversal field.

Control of field driven domain wall (DW) motion by transversal fields: suppression of Walker breakdown and giant velocities.

S. Glathe¹, R. Mattheis¹, T. Mikolajick²

1. Photonic Instrumentation, IPHT, Jena, Germany; 2. Institute of Electronic and Sensor Materials, TU Bergakademie Freiberg, Freiberg, Germany

In the past few years field and current driven dw motion became a field of strong experimental and theoretical activity e.g. [1 - 3]. These efforts are driven by potential application in data storage (Race Track Memory [4]) and sensor device applications (Multiturn sensor [5]). Within the development of the Multiturn sensor the question occurred in which way large transversal fields can influence the propagation of DWs. Up to now there are only micromagnetic simulations at low transversal fields dealing with this topic [6, 7].

We investigated the DW motion under the influence of strong transversal fields in Permalloy (Py) nanostrips. The 20 nm thick Py layer is part of a GMR stack deposited using physical vapour deposition and patterned via photolithography and Ar ion etching under tilt. Due to a magnetisation reversal of the Py sense layer we get a change in the GMR resistance in the order of 5 %. This variation of the GMR resistance is measured in terms of a change in voltage. Thus we investigated the DW propagation by means of time resolved voltage measurements. Using the slope of the voltage jump one can calculate the DW velocity. The required longitudinal and transversal fields are generated by two coils adjusted orthogonally to each other.

To perform a measurement we first applied a constant transversal field and then an alternating longitudinal field by means of a triangular signal. If the nucleation field of a DW is reached a DW is injected into the nanostrips and driven through the whole Py wire within some μ s at constant transversal and longitudinal driving field without pinning events.

Fig. 1 shows the longitudinal component of the nucleation field (bold), which is the driving field H_{dr} of the DW, and the DW velocity (thin) as a function of the transversal field. The longitudinal component of the driving field is reduced with increasing transversal field. This can be explained by the reduction of the DW angle by increasing the transversal field and thus a reduction of exchange energy stored in the DW. Micromagnetic simulations show two effects of the transversal field on a static DW. Firstly, the DW width is increased by the factor of two ($H_t = 32$ kA/m) and secondly, the magnetisation direction of the domains is tilted in the direction of the transversal field, resulting in a reduced DW angle. At highest applied transversal fields of $H_t = 50$ kA/m one gets a DW angle in the order of 60° and a longitudinal field component in the order of 0,8 kA/m is necessary for the nucleation of the reversed domain.

For small transversal fields ($|H_t| < 10$ kA/m) the velocity decreases slightly with decreasing H_{dr} . Hence we get a positive DW mobility (dv/dH_{dr}). Increasing the transversal field to higher values a jump of the DW velocity occurs at $|H_t| = 20$ kA/m by the factor of about 2. This rise is due to the suppression of the Walker breakdown process [1, 7], as shown in detail elsewhere. The transversal field stabilizes the DW core magnetisation parallel to H_t and suppresses the nucleation and propagation of an antivortex and vortex respectively. Thus we get DW motion below Walker breakdown at relatively high driving fields compared to DW motion without transversal fields [3].

Increasing the transversal fields to values above 20 kA/m we get a further rise of DW velocity while the driving field H_{dr} is decreased, resulting in a negative DW mobility. For pure longitudinal fields ($H_t=0$) one gets a negative DW mobility only in the transition region between DW motion above and below Walker breakdown [3]. This transition is observed at $|H_{trans}| = 20$ kA/m as explained above. Thus the rise in DW velocity for $|H_{trans}| > 20$ kA/m must have different origin. We explain

this behaviour with the broadening of the DW and the reduction of the DW angle. A 1-D-model developed by Allwood et al. [8] predicts a dramatic increase of DW velocity with decreasing DW angle and a moderate rise with increasing DW width. Due to these effects we get maximum velocities of $v = 8000$ m/s, which is 5 times higher than the maximum published velocity of field driven DWs in Py [9].

Domain-Wall Trapping by Localized Field on Submicron Permalloy Wire.

L. Ji, A. Orlov, G. H. Bernstein, W. Porod

Electrical Engineering, University of Notre Dame, Notre Dame, IN

We present a novel method to trap a domain wall on a submicron permalloy wire. The trapping is accomplished by the stray field generated by a rectangular permalloy bar placed at a right angle next to the wire.

Simulations of this structure have been performed by the standard OOMMF simulator. The wire dimension is 7 μm in length, including a large circular pad to initiate the magnetic switching, and a sharpened end for domain wall annihilation. For this study, the wire width is 200nm. A 300*1500nm rectangular bar is placed 30nm away from the wire, as shown in Figure 1a). The thickness of the wire and the bar is 10nm. Initially, the structure is saturated in the +y direction perpendicular to the wire. When the external field is relaxed, the bar will maintain the magnetization in the +y direction, while on the wire, a head-to-head domain wall is naturally trapped in the vicinity of the bar, as shown in Figure 1b). Then, an external field is gradually increased in the +x direction along the wire. The domain wall will remain at that position until the external field is sufficiently large to drive it out. For our geometry, this critical field is +75 Oe. After +75 Oe, the wire is magnetized to the right. When the external field is decreased to zero and then is increased in the -x direction, switching starts from the circular pad. At about -70 Oe, the domain wall moves out of the pad and starts to propagate along the wire. When it travels to the left of the rectangular bar, the stray field from the bar is pointing to the right, which opposes the external field, and a domain wall is trapped until the external field is large enough to drive it out, as shown in Figure 1c) and 1d). However, if the field is increased to +x direction again, when a domain wall travels to the left of the bar, the stray field would facilitate the propagation of domain wall, so no domain wall will be trapped.

Sample with the same dimension as in the above simulation was fabricated by electron beam lithography. A SEM image is shown in Figure 2 a). Copper contacts are made upon the wire as shown in Figure 2b) for four-probe measurement. Sample is first magnetized in the +y direction, when the external field is removed, the rectangular bar is magnetized upwards. And a domain wall is trapped on the wire as shown in MFM image, as shown in Figure 3. The wire is then magnetized in the +x direction by a field of 200 Oe.

A full magneto-resistance resistance measurement loop is then performed. External field is increased from 0 to +80 Oe in the +x direction first. No domain wall is trapped. When the field starts to decrease in the -x direction, a domain wall is trapped between -40~ -60 Oe, indicated by a resistance change of about 0.2 Ω due to AMR effect. The magneto-resistance measurement result can be observed in Figure 4.

Due to the fact that domain wall is only trapped on one side of the loop and it is purely decided by the magnetization of the rectangular bar, it can be used as an electronic read-out for the magnetic QCA(Magnetic Quantum Cellular Automata)[1] to determine the output dot's magnetization. This method of domain wall trapping may also be useful for the study of current-induced domain-wall motion, since it does not require a physical constriction on the wire [2].

Spin transfer torque switched elements with a perpendicular magnetic anisotropy were thought to be suitable for high density magnetoresistive random access memory (MRAM) application because they have potentials to reduce the critical switching current density while maintaining the thermal stability at small element size [1]. Some experimental results for the spin transfer torque switching in MgO based MTJs with perpendicular magnetic anisotropy were reported [2,3]. However, reliability of the materials is not adequate. In this paper, the MgO based MTJ film with L1₀-FePt electrodes, which was a promising material for high density MRAM, was studied and successfully developed to have high TMR ratio over 100 % at room temperature.

The MTJ stacks of a capping-layer/top L1₀-FePt(3)/MgO(1.5)/interface-layer(2)/bottom L1₀-FePt(10)/underlayer/substrate (thicknesses in nanometers) were deposited on thermal oxidized Si substrates by a DC/RF magnetron sputtering method, where the interface layers consisted of polycrystalline Fe and FeCo. The bottom L1₀-FePt electrode was formed on a heated substrate. The top L1₀-FePt electrode was annealed in-situ after deposition. The substrate temperature and the post-annealing temperature were optimized in the range from 673 K to 773 K. Magnetic properties were measured using a vibrating sample magnetometer. The TMR ratio was measured at room temperature by the current-in-plane tunneling method [4].

Figure 1 shows a typical magnetization versus applied magnetic field (M-H) curve of the FePt/MgO/Fe/FePt-MTJ film. The enough coercive force difference between the top and bottom electrodes, whose coercive forces were 0.6 kOe and 2.5 kOe, respectively, was obtained. A typical TMR ratio was around 100 % and a maximum value was 120 %. Then, Figure 2 shows the plots of the TMR ratio as a function of the top FePt electrode thickness for the FePt/MgO/FeCo/FePt-MTJ films. The TMR ratio was not dependent on the top FePt electrode thickness and approximately constant around 100 %. A transmission electron microscopy analysis for the FePt/MgO/Fe/FePt-MTJ film shows that the smooth MgO barrier with good (001) orientation was formed and the FePt electrodes had high (001) orientation (not shown here). On the other hands, the TMR ratio was decreased as the interface Fe layer thickness became thin. No TMR was observed in the case that the interface Fe layer was not inserted (not shown here). This is because the lattice mismatch at the MgO(001)/FePt(001) interface is too large for the MgO film to grow epitaxially and the morphology and the (001) orientation of the MgO barrier become degraded. The insertion of the interface layer is required for the relaxation of the lattice mismatch between MgO(001) and FePt(001). Consequently, the high TMR ratio over 100 % in the L1₀-FePt/MgO/Fe(FeCo)/L1₀-FePt MTJ films was obtained at room temperature. The recent theoretical calculation predicted the TMR over 300 % in an epitaxial L1₀-FePt/MgO/L1₀-FePt(001) MTJ [5] as well as the large one in an epitaxial Fe/MgO/Fe(001) MTJ [6]. The much higher TMR ratio can be obtained by optimization of the interface layer inserted between MgO and FePt.

Interfacial Oxidation Enhanced Perpendicular Magnetic Anisotropy in Low Resistance Magnetic Tunnel Junctions Composed of Co/Pt Multilayer Electrodes.

J. Park¹, C. Park², J. Zhu¹

Introduction

Magnetic tunnel junctions (MTJs) using perpendicular magnetic anisotropy (PMA) have been suggested as the promising candidate to overcome the density limits of the present in-plane-magnetized junctions for scalable magnetic memory application [1]. In the previous study, authors experimentally demonstrated pMTJs composed of Co/Pt multilayers with PMA, which yielded robust tunneling magnetoresistance (TMR) of ~15% TMR ratio [2]. In this study, low resistive pMTJs with thin AlOx tunnel barrier by natural oxidation have been investigated. On optimizing the tunnel barrier, the authors focus on verifying the effect of oxidizing Co monolayer adjacent to AlOx barrier. This has been designed in order to enhance the PMA of Co/Pt multilayer by producing rich Co-O bonding at the interface [3]. As results, magnetization switching behavior has been improved and well-defined transition between parallel and anti-parallel states is obtained at the pMTJ device of ~100 $\Omega \cdot \mu\text{m}^2$ resistance-area (RA) product.

Experimental

All film stacks including magnetic layers, leads and tunnel barrier were prepared by rf/dc sputtering below 3×10^{-7} Torr base pressure. The typical oxidation procedure of AlOx barrier and Co adjacent layers is depicted in Fig. 1. In this figure, each natural oxidation process has been optimized for the full oxidation of ~5 Å Al layer. For enriching Co-O bonding at the bottom interface, 3 Å thick Al is deposited on top of the bottom Co adjacent layer prior to the 1st oxidation. For the top interface oxidation, monolayer thick Co is deposited on top of 3 Å Al layer followed by the 3rd oxidation step. After film deposition, magnetization switching has been investigated by film level perpendicular hysteresis and TMR transfer curves of micro-fabricated MTJ test patterns.

Results and discussion

The oxidation effect of adjacent Co monolayer on perpendicular hysteresis loop is shown in Fig. 2. MTJ film without Co oxidation has dispersed switching field both in soft and hard layers, which can be attributed to the lack of Co/Pt interface anisotropy in the vicinity of Co-AlOx interface and orientational incoherence especially on the soft Co adjacent layer on top of amorphous AlOx layer. On the contrary, MTJ film with treated Co adjacent layers shows sharp magnetization switching in the both layers. This improvement is also confirmed in the TMR measurement result. Fig. 3 shows MR behavior of two MTJ devices with (a) non-oxidized and (b) oxidized Co interfacial layers. In the non-treated MTJ device, the magnetization of the soft layer appears to be completely tilted with the hard layer being partially tilted. However, the treated device shows well-defined parallel and anti-parallel states and reproducible magnetization switching at the junction of ~100 $\Omega \cdot \mu\text{m}^2$ RA product. Thus abundant Co-O bonding at the barrier interface is believed to enhance the PMA of Co/Pt multilayer and magnetization switching property. This consideration should be very important for possible perpendicular spin-torque-transfer application, in which thick adjacent layers are expected to be advantageous for high spin polarization. Therefore, the effect of adjacent layer thickness on the PMA will be also discussed.

A magnetic tunnel junction consisting of two ferromagnetic (FM) layers separated by a tunnel barrier exhibits a large tunnel magnetoresistance (TMR), depending on the relative magnetization direction of the two FM layers. This originates from the spin-polarized tunneling from the FM/Insulator interface. Recently, a similar magnetoresistance effect (so-called tunneling anisotropic magnetoresistance, TAMR) is observed in the tunnel junctions with only one FM layer where the TMR is not present. Studies in ferromagnetic semiconductor devices showed that TAMR response can in principle be huge and richer than TMR, with the magnitude and sign dependent on the magnetic field orientation and electric fields. Theoretical work predicted [1] that the TAMR effect is generic in FMs with spin orbit(SO)-coupling, including the transition metal systems. Experimental demonstration of the TAMR in a metallic tunnel junction has recently been reported in an epitaxial Fe/GaAs/Au [2] and CoFe/tunnel barrier (MgO, Al₂O₃)/CoFe structures [3]. The observed TAMR in those structures is relatively small, below 0.5%, consistent with the weak SO-coupling. In this work we present a study of tunnel devices with a single FM electrode of Co/Pt multilayer in which large and tunable magnetic anisotropies are generated at the interfaces by combined effects of induced moments and strong SO-coupling. We show that engineering the interfaces adjacent to the tunnel barrier enhances the TAMR effect by an order(s) of magnitude.

Our tunneling devices, schematically illustrated in Fig. 1(a), were grown by magnetron sputtering on a thermally oxidized Si wafer. The Ta/Pt seed layer was chosen to initiate growth of a textured Pt(111)/Co ferromagnetic film with a strong out-of-plane magnetocrystalline anisotropy. The tunnel barrier was fabricated by plasma oxidation of 1.6 nm Al layer. Two types of multilayers are investigated: samples A have the alternating sequence of Pt and Co layers beneath the AlO_x barrier terminated by 0.5 nm (two monolayers) Pt film while samples B have this top Pt film in the FM electrode omitted. Devices were mounted on a rotating sample holder allowing the application of magnetic fields up to 10 T at an arbitrary in-plane and out-of-plane angle.

Fig. 1(b) compares magnetization and magnetotransport anisotropy data measured in samples A and B. Wide and square hysteresis loops in perpendicular magnetic fields, shown in the insets, confirm the strong magnetic anisotropy with out-of-plane easy axis in both devices. The anisotropic magnetotransport in the two tunneling devices is, however, fundamentally different. The resistances of the device are taken at a magnetic field of 10T rotating from the perpendicular ($\theta=0$) to the in-plane ($\theta=90$) direction. In both samples the TAMR has the expected uniaxial symmetry but the magnitude of the effect is enhanced by 2 orders of magnitude in sample A. As the transport characteristics of TMR or TAMR tunneling devices are expected to be strongly influenced by the nature of the surface layers of the FM electrode we attribute the large TAMR signal in sample A to the induced moment and strong SO-coupling in the two-monolayer Pt film inserted between Co and the tunnel barrier. In sample B, the topmost layer in contact to the barrier is 1 nm Co film and therefore this tunneling device behaves effectively as a Co/barrier/normal metal for which the magnetotransport anisotropy is expected to be comparably weak.

The analysis is based on calculating density of states (DOS) anisotropies in the FM electrode with respect to the orientation of the magnetization (Fig1. (c)). For the Co/Pt model system we find a

complex structure of the DOS near the Fermi energy with the main features shifted by 10's of meV when comparing the two magnetization orientation curves. The Co-film, on the other hand, has a nearly featureless DOS near the Fermi level which depends very weakly on the magnetization direction. The relative difference between DOSs for the in-plane and out-of-plane magnetizations, which we relate to the tunneling conductance anisotropy, shows an oscillatory behavior as a function of energy for the Co/Pt with a magnitude of up to 20% (Fig 1. (d)). For the Co film the magnitude and the energy dependence of the anisotropy is substantially weaker. These theoretical results are qualitatively consistent with measurements in samples A and B presented above. We will discuss further on the dependence of the TAMR on magnetic field, temperature, and bias voltage for both samples.

Crossover from Kondo assisted suppression to cotunneling enhancement of tunneling magnetoresistance via ferromagnetic nanodots in MgO tunnel barriers.

H. Yang^{1,2}, S. Yang¹, S. Parkin¹

1. IBM Almaden Research Center, San Jose, CA; 2. ECE, National University of Singapore, Singapore, Singapore

The magneto-transport properties of magnetic granular alloys and magnetic tunnel junction devices with magnetic nanodots embedded in amorphous dielectric matrices [1,2] and tunnel barriers [3,4] respectively, have been studied by several groups but no systematic studies of the dependence on these properties on the nanodot size have been made.

Here we show that a wide range of magneto-transport properties in magnetic tunnel junctions with barriers containing magnetic nanodots can be accounted for by Kondo-like physics and that as the size of these nanodots is systematically increased the tunnelling properties change from those characteristic of Kondo tunnelling which suppresses the TMR near zero bias, to those of correlated tunneling which increases the TMR at low bias.

The MTJ device is composed of CoFe ferromagnetic (F) electrodes, and an MgO tunnel barrier. Both F electrodes are exchange biased but the exchange bias field is designed to be significantly stronger for the lower electrode so that the moment of each electrode can be switched independently. A thin CoFe layer of nominal thickness t_{ND} is inserted in the middle of the MgO layer. When this layer is thinner than ~ 2 nm it forms a discontinuous layer of nanodots, as revealed by plan-view transmission electron microscopy (TEM). This means that the diameter of the nanodots is considerably larger than the nominal layer thickness.

The magneto-transport properties of the MTJs are considerably affected by the presence of the nanodots in the MgO tunnel barrier, as shown in Figure 1. In particular, as the temperature is reduced, the resistance of the MTJ increases, but at a greater rate, the smaller the nanodot size. This is due to a Coulomb blockade (CB) effect, which has previously been seen in MTJs formed with discontinuous Co and Fe layers within alumina [4-7] and MgO [8] tunnel barriers. At high temperatures and bias voltages the tunneling is dominated by sequential tunneling through the nanodots since the barrier is very thick (thus direct tunneling across the MgO barrier is small). The nanodots are so small that there is a significant increase in energy when an electron tunnels onto a dot which, at low temperature and bias compared to this energy, thereby depresses the tunneling conductance across the MTJ device. From the fits of the temperature dependence of the tunneling resistance a characteristic temperature T_{CB} , below which CB effects are important, can be derived. T_{CB} is proportional to the charging energy needed to add a single electron to the dot. CB effects are observed when $t_{\text{ND}} < 1.8$ nm with T_{CB} increasing to ~ 330 K when $t_{\text{ND}} = 0.05$ nm. The calculated CB energy is consistent with the average size of the nanodots inferred from plan-view TEM micrographs. For example, when $t_{\text{ND}} = 0.45$ nm, the CB energy is ~ 53 meV which gives a nanodot diameter of ~ 2.6 nm.

There are several other characteristic features of Kondo assisted tunneling, which we observe in MTJs with nanodots. One of these is a peak in the tunneling conductance versus bias voltage curve centered at zero voltage which has a characteristic width proportional to the strength of the Kondo interaction i.e. the Kondo temperature T_{K} . The crossover from Kondo to cotunneling behaviour is likely correlated with suppression of the fluctuations of the nanodot magnetic moments. Although the tunneling characteristics for the smallest nanodots can be described by Kondo physics, the possibility of observing Kondo phenomenon involving quantum dots with large magnetic moments requires a stronger theoretical foundation and remains an open question.

What is now emerging in the field of spintronics is the investigation of the spin transport properties of structures in which the central element is a nano-object connected to ferromagnetic electrodes. The capacitance of this nano-object can be small enough that the energy needed to add an electron on it becomes larger than the thermal energy at low temperature, leading to discrete voltage jumps of e/C in the I-V characteristics called Coulomb blockade "staircases". The interesting aspects of this new field of nano-spintronics come from the interplay between this Coulomb blockade effects and magnetic properties [1]. This subject has motivated a lot of theoretical works in the past decade.

They predict the observation of a magnetoresistance effect related to spin dependant transport and spin accumulation in systems with at least two ferromagnetic elements [2,3].

We investigate Coulomb blockade and magnetic properties in a single nonmagnetic metallic nanoparticle connected to ferromagnetic leads. A layer containing metallic clusters of a few nanometers in diameter embedded in an oxide layer of alumina is grown by sputtering. After an optical lithography process, the fabrication is carried out using a conductive tip AFM where the nanoindentation process is electrically monitored in real time. With this simple technique, we contact single particles of a few nanometers in size [4]. A schematic representation of the sample is shown in figure 1.

The I-V characteristics of this system measured at 1.5K show typical Coulomb blockade effects and are in excellent agreement with numerical simulations of transport through a unique nanoparticle (see figure 2). We observe magnetoresistance effects in samples containing single Au, Cu and Al nanoparticles connected with ferromagnetic electrodes. Besides spin accumulation effects, we are able to distinguish another type of magneto-Coulomb effect. This effect is linked to the magnetic anisotropy of the ferromagnetic electrodes and can occur even when a single ferromagnetic element is present in the system.

A measurement of this effect is shown in figure 2. We present I-V curves obtained at low temperature on a sample containing an Au nanoparticle of around 5nm in diameter with a magnetic field of 500 Oe applied in different directions. We see a clear difference in the I-V curves measured with a magnetic field applied at 0 and 90 degrees. We find out by realizing simulations that the magnetic electrode acts as a gate on the single electron device. The magnetoresistance presents an oscillation as function of bias voltage and can be as strong as -70% showing evidence for Coulomb blockade driven anisotropic magnetoresistance in metallic single electron devices.

Introduction

Some of full-Heusler alloys (Co_2MnSi , Co_2MnGe , etc.) attract much interest in recent spintronics field because they have been predicted to possess half-metallic electronic structure. We have demonstrated giant TMR ratio of 159% at 2 K in magnetic tunnel junctions (MTJs) with $\text{Co}_2\text{MnSi}/\text{Al-O}/\text{CoFe}$ structure; this result indicates the half-metallic property of Co_2MnSi (CMS). [1] However, the TMR ratio decreased drastically with increasing of temperature. We considered that the large temperature dependence was originated from the destruction of half-metallic gap due to thermal fluctuation of DOS at the Fermi level.

Although this TMR ratio is outstanding in the MTJs with conventional Al-O barrier, recent works on the MTJs with MgO barrier showed more excellent performance due to coherent tunneling mechanism through (001)-oriented crystalline MgO barrier. [2] Miura et al. showed coherent tunneling through the Δ_1 band could also occur in a CMS/MgO/CMS-MTJ, theoretically. [3] As the edge of Δ_1 band of CMS exists apart from the Fermi level, a large TMR ratio at RT can be realized in MTJs using both CMS electrode and MgO tunneling barrier.

In this study, we fabricated the high-quality $\text{Co}_2\text{MnSi}/\text{MgO}/\text{CoFe}$ -MTJs and investigated their spin-dependent tunneling properties.

Experiments

We fabricated fully-epitaxial MTJs with $\text{Co}_2\text{MnSi}/\text{MgO}/\text{CoFe}$ -structure on the single crystalline MgO substrates. The CMS bottom electrode was deposited by magnetron sputtering system at RT and annealed at 500°C to obtain good chemical ordering. The MgO tunneling barrier was formed by EB-evaporation system under 10^{-7} Pa. All the MTJs were patterned into 4-terminal structure by photo-lithography and Ar ion milling. The differential conductance G ($=dI/dV$) was measured using standard ac lock-in technique. A positive bias voltage is defined as electrons tunneling from the bottom CMS to the top CoFe electrode.

Results and discussions

Figure 1 shows temperature dependence of TMR ratio and the typical MR curves for the $\text{Co}_2\text{MnSi}/\text{MgO}/\text{CoFe}$ -MTJ and the $\text{Co}_2\text{MnSi}/\text{Al-O}/\text{CoFe}$ -MTJ. The $\text{Co}_2\text{MnSi}/\text{MgO}/\text{CoFe}$ -MTJ shows TMR ratios of 217% at 300 K and 753% at 2 K. The TMR ratio of 753% at LT is the highest in MTJs using Heusler alloy electrodes and larger than that for $\text{CoFe}/\text{MgO}/\text{CoFe}$ -MTJ, 300%, reported in ref [4]. This result reveals that half-metallicity of CMS can be realized in the MTJ with MgO tunneling barrier. In addition, the TMR ratio at RT is drastically improved, compared with that for the MTJ with Al-O barrier. However, the temperature dependence of TMR ratio is still large.

Figure 2-(a) shows the bias voltage dependence of conductance for parallel magnetization configuration (G_P). For reference, G_P for the CMS/Al-O/CoFe-MTJ is shown together. In the CMS/Al-O/CoFe-MTJ, the crucial rise of G_P is observed at the negative bias voltage. This behavior of G_P reflects very small energy separation (ca. 10 meV) between the conduction band and the Fermi level of the CMS. [5] On the other hand, in the CMS/MgO/CoFe-MTJ, the crucial rise of G_P at the negative bias voltage is suppressed at both RT and LT. In addition, dip structures, being similar to

that for the $\text{CoFeB}/\text{MgO}/\text{CoFeB}$ -MTJ reported previously, are observed at ± 400 mV. [6] We infer that these dip structures are related to the coherent tunneling process through the MgO barrier. Figure 2-(b) shows the bias voltage dependence of conductance for anti-parallel magnetization configuration (G_{AP}). G_{AP} at LT increases sharply at low bias voltage compared with G_P or G_{AP} at RT. This large voltage dependence of G_{AP} at low bias can be originated from inelastic tunneling processes at the CMS/MgO interface. There are two possible explanations for the large inelastic tunneling probability in the MTJs with CMS electrodes; magnon excitations due to the low Curie temperature at the CMS surface and magnetic impurity scatterings caused by Mn and Si oxide. In summary, we have succeeded to fabricate the high-quality $\text{Co}_2\text{MnSi}/\text{MgO}/\text{CoFe}$ -MTJs and obtained the highest TMR ratio in MTJs using Heusler alloy electrodes.

Co-based full-Heusler alloy (Co_2YZ) thin films have attracted much interest as a promising ferromagnetic electrode material for spintronic devices [1,2]. This is because of the half-metallic ferromagnetic (HMF) nature theoretically predicted for many of these alloys, and because of their high Curie temperatures, which are well above room temperature (RT). We recently demonstrated high tunnel magnetoresistance (TMR) ratios of up to 182% at RT and 705% at 4.2 K for fully epitaxial magnetic tunnel junctions (MTJs) with Co_2MnSi (CMS) thin films as both the lower and upper electrodes and a MgO (001) tunnel barrier [3]. Our purpose in the present study is to investigate the bias voltage (V) dependence of the spin-dependent tunneling conductance and clarify its origin for the CMS/MgO/CMS MTJs (CMS-MTJs) that feature high TMR ratios. We investigated V dependences of R_p and R_{AP} , where R_p and R_{AP} are the respective tunneling resistances for the parallel (P) and antiparallel (AP) magnetization alignments, along with the differential conductance ($G = dI/dV$) vs V characteristics for P and AP (G_p and G_{AP} , respectively). The latter characteristics were measured using a standard lock-in method. The second derivative d^2I/dV^2 was obtained mathematically from the dI/dV vs V characteristics.

Figure 1(a) shows R_p and R_{AP} as a function of V at 4.2 K for a CMS-MTJ that showed a TMR ratio of 679% at 4.2 K (176% at RT). The bias voltage was defined with respect to the lower CMS electrode. R_{AP} of the CMS-MTJ showed a strong V dependence, especially in the V range of $|V| \leq 100$ mV, while R_p exhibited a very weak dependence on V . This highly cusp-like dependence of R_{AP} in the range of $|V| \leq 100$ mV faded away at RT.

Figure 1(b) shows G vs V for P and AP at 4.2 K. A marked increase of G_{AP} with increasing V was clearly visible in the V range of $|V| \leq 70$ mV, which corresponds to the cusp-like structure in the R_{AP} vs V . Figure 2 shows typical d^2I/dV^2 spectra at 4.2 K. Clear structures in the range of $|V| \leq 100$ mV characterized by peaks at around ± 4 mV are observed in the d^2I/dV^2 spectra for AP, indicating magnon excitations due to hot electrons in the collector.

The G_p spectra exhibited a broad, nearly flat region for $|V| \leq 0.36$ V, and G_p increased sharply at $V \sim 0.36$ V. The G_{AP} spectra showed a similar region for $|V| \leq 0.21$ V except the range of $|V| \leq 0.07$ V. These sharp increases can be ascribed to direct tunneling from the minority-spin band below the Fermi level (E_F) or to the minority-spin band above E_F . From the characteristic structures in both spectra of G and d^2I/dV^2 indicated by the arrows in Figs. 1(b) and 2, we estimated an energy gap for the minority-spin band of about 0.36 eV with the E_F position being near the middle of the half-metallic gap.

These spin-dependent tunneling characteristics for the CMS-MTJs along with the large TMR ratios can be explained as follows: 1) Due to the half-metallic gap, the tunneling conductance for AP should be significantly decreased. 2) At low temperatures, where kT energy is much lower than the magnon excitation energy, we should consider only the tunneling from the majority-spin band in the emitter to the interface states of the minority-spin band in the collector for AP [4]. Hot electrons associated with the bias voltage excite magnons in the collector. Electrons are then scattered from the interface states in the minority-spin band to the majority-spin band in the collector. This results in the considerable increase of the tunnel conductance for AP by increasing V in the range of $|V| \leq 100$ mV.

In summary, we showed a HMF nature of CMS thin films incorporated into MTJs as ferromagnetic electrodes through the spin-dependent tunneling conductance characteristics. It was experimentally shown that spin-flip scattering from the interface states of the minority-spin band to the majority-spin band in the collector electrode by the hot-electron effect is a dominant factor for the tunneling characteristics of half-metallic Heusler alloy-based MTJs.

Spin-polarized tunneling characteristics of the room temperature spin filter CoFe₂O₄.

A. V. Ramos¹, R. Mattana², F. Petroff², T. S. Santos^{3,4}, G. Miao³, J. S. Moodera³

1. DSM/DRECAM/SPCSI, CEA Saclay, Gif-sur-Yvette, France; 2. Unite Mixte de Physique, CNRS/Thales, Palaiseau, France; 3. Francis Bitter Magnet Laboratory, MIT, Cambridge, MA; 4. Argonne National Laboratory, Argonne, IL

The generation of highly spin-polarized electron currents at room temperature is the basis of most spin-based device technologies. One approach known as spin filtering, has the potential of generating 100%-polarized currents by the spin selective transport of electrons across a ferromagnetic tunnel barrier [1]. While efficient spin filtering at room temperature is highly attractive for applications such as ultra sensitive detectors and spin injection into semiconductors, the selection of materials having the necessary magnetic and electronic properties is quite limited. Cobalt ferrite (CoFe₂O₄) is one very good candidate because it is a ferrimagnetic insulator with a remarkably high Curie temperature (793 K). In this work, we demonstrate that room temperature spin filtering may indeed be obtained in magnetic tunnel junctions (MTJs) containing CoFe₂O₄ tunnel barriers.

Fully epitaxial MTJs containing CoFe₂O₄(111) tunnel barriers have been grown by oxygen plasma-assisted molecular beam epitaxy. Their structural, chemical and magnetic properties are studied by a number of in situ and ex situ characterization techniques [2], as these are known to significantly impact the spin filter capability of complex magnetic oxides. We also pay special attention to the magnetization reversal behavior of the magnetic barrier and its magnetic counter electrode, which is yet another crucial step towards the successful measurement of TMR. Following the optimization of the CoFe₂O₄-based systems, we focus on the spin-polarized tunneling characteristics using two different measurement techniques: Tunneling magnetoresistance (TMR) measurements and the Meservey Tedrow technique. These spin polarized transport measurements first reveal significant TMR values both at low temperature and at room temperature [3]. In addition, the TMR ratio follows a unique bias dependence that has been theoretically predicted to be the signature of spin filtering in magnetic tunnel barriers. In the case of the Meservey Tedrow measurements, we once again demonstrate spin polarization in CoFe₂O₄-based tunnel barriers using Al superconducting electrodes as the spin analyzer. The results from the spin polarized transport measurements allow us to address the influence of defects such as oxygen vacancies on the spin polarization, as well as the role played by different spin-detecting electrodes. We therefore show that CoFe₂O₄ tunnel barriers provide a model system to investigate spin filtering in a wide range of temperatures.

***In Situ* Lorentz Study of Disorder, Fluctuations, and Breakdown in Magnetic Tunnel Junctions.**

S. E. Russek, J. M. Shaw, R. Geiss

National Institute of Standards and Technology, Boulder, CO

Nanoscale disorder and fluctuations in magnetic tunnel junctions (MTJs) have been imaged using TEM and Lorentz microscopy. The observed disorder and fluctuations give rise to Barkhausen and $1/f$ noise in MTJ sensors, which limit the ability of MTJs to be used in pT sensor applications. To study how nanoscale magnetic and microstructural variations affect device performance an active probe was fabricated that allows imaging, in both TEM and Lorentz modes, of devices while magnetic fields and currents are applied. The probe has xy field coils, integrated device current supply and low noise amplifiers. MTJ devices were fabricated on silicon nitride membranes with elliptical shapes and dimensions down to $3\ \mu\text{m}$ as seen in Fig. 1. Both device orientations, with the fixed layer parallel and perpendicular to the easy axis, are included on each sample. The layer thicknesses of the MTJ stack, dielectrics, and electrodes were reduced to allow high resolution imaging of active devices in the TEM. The stack structure was $\text{Si}_3\text{N}_4/5\text{nm Ta}/5\text{nm Cu}/10\text{nm Ir}_{20}\text{Mn}_{80}/3\text{nm Co}_{90}\text{Fe}_{10}/1.8\text{ nm Al}_2\text{O}_3/2\text{ nm Co}_{90}\text{Fe}_{10}/20\text{ nm Ni}_{80}\text{Fe}_{20}/5\text{nm Ta}$ and several process conditions using different preoxidation treatments before barrier formation were used to change the interfacial morphology.

The magnetic structure in both the 3 nm thick $\text{Co}_{90}\text{Fe}_{10}$ fixed layer as well as in the 22 nm thick $\text{Co}_{90}\text{Fe}_{10}/\text{Ni}_{80}\text{Fe}_{20}$ free layer were resolved as seen in Fig. 2. The patterned elliptical structures consist of both free and fixed layer while the surrounding area consists of only the lower fixed layer. In unannealed samples there was considerable disorder in the fixed layer, which is seen as a ripple structure outside the ellipse. The structure in the fixed layer disappeared after annealing in a magnetic field as seen in Fig. 3. The unannealed MTJs, as shown in Figs. 2 and 3, show a complex multidomain state at zero field. The annealed MTJs show less disorder although they still show the presence of vortices.

Fig. 4 shows a $20\ \mu\text{m}$ MTJ which has a trapped vortex. As seen in the figure, the vortex can be moved *in situ* with an applied magnetic field. The *in-situ* magnetoresistance is shown along with the *ex-situ* magnetoresistance data taken on a probe station before mounting on the Lorentz probe. The left inset shows voltage versus current (IV) data taken while imaging in the TEM.

In addition to monitoring the resistance and IV curves during imaging, thermal fluctuations of the magnetization and breakdown phenomena can be observed while the current and field remain fixed. The Lorentz images can be obtained at 30 frames/s which is well suited to observing sources of $1/f$ noise and barrier breakdown. At high voltages across the device breakdown events occur and localized damaged regions are formed which can be seen in both TEM and Lorentz mode.

MTJ stacks with preoxidation steps before formation of the tunnel barrier showed less ripple structure [1], which correlates well with cross sectional TEM images showing that pre-oxidation improves interface flatness.

Studies of time-dependent dielectric breakdown (TDDDB) in magnetic tunnel junctions (MTJ) are usually carried out by applying a DC voltage while recording the time to breakdown [1]. The normal operation conditions of an MTJ in a memory device require applying a large number of read/write voltage pulses. This work reports on the breakdown behavior of MgO tunnel barrier when submitted to consecutive voltage pulses. The studied junction structure was Ta 50/ PtMn 20/ CoFe 2/ Ru 0.8/ CoFeB 2/ MgO 1.1/ CoFeB 2.5/ NiFe 2.5/ IrMn 6.5/ Ta 5 (thickness in nm). The measured devices were ellipses of $0.25\mu\text{m} \times 0.3\mu\text{m}$ nominal diameter showing 35% TMR and an $R \times A$ value of $150\text{--}200 \Omega\mu\text{m}^2$.

The experimental procedure consisted in applying a sequence of pulses of constant width and amplitude up to observation of barrier breakdown. This has been repeated for 10ns, 100ns and 1 μs pulse widths and 1.7V pulse amplitude, corresponding to an electric field of $15 \times 10^9 \text{ V/m}$. The results are shown in Fig.1 where the fraction of barrier failures is plotted as a function of the total cumulated pulse time. The data are well described by a Weibull distribution, clearly establishing an equivalence between the present reliability test procedure and previous studies of the time to breakdown distribution on junctions under DC bias [1,2]. The Weibull distribution is defined by the scale parameter η , representing the total cumulated time for which 63.2% of MTJ have failed, and shape parameter β , the slope of a straight line fit to the data, reflecting the distribution of time dependent breakdown failures. The β parameter generally depends on the quality of MTJ fabrication (deposition and patterning), whereas η is mostly dependent on the test conditions [2], in particular the applied voltage.

The results also show that η has two different regimes. In the short pulse width regime (below 100ns), there is a significant increase in η , while for pulses of 100ns and longer, η remains essentially unchanged. This phenomenon has already been observed in thicker SiO_2 barriers where it is attributed to a combination of charge trap creation and trapped charge relaxation [3]. However the observed increase by three orders of magnitude of the total cumulated time to barrier breakdown failure is much larger than initially expected. This might be related to a temperature effect, since the applied 1.2mW pulse power should result in a quasi-static temperature increase of 130°C . For longer pulse widths, the device has time to reach quasi-static thermal equilibrium. In contrast, for 10ns pulse widths, this is not the case since the characteristic temperature rise time has been measured to be 8-10ns. To verify this assumption, measurements were performed at 100°C and 150°C using a hot chuck while applying 10ns pulses. The effect of temperature increase is an acceleration of the barrier breakdown. Both η and β , the parameters describing the Weibull lifetime distribution, are clearly affected by the temperature. At 150°C , the β parameter increases to the value found for 100ns pulses and longer while η , although reduced from its room temperature value, still remains greater than η for the long pulse widths. Therefore when choosing the operation conditions to optimize junction reliability, i.e maximize both η and β , the junction temperature has to be taken into account as well as pulse voltage and duration.

At the interface between « classic » spintronics and organic electronics, organic spintronics has been the focus of a growing interest since 2002 and the first observation of magnetoresistance effects through sexithiophene (T6) films [1]. Since then, most of the successful studies have dealt with aluminium tris(8-hydroxyquinoline) (Alq3). Usually a thick Alq3 layer (about 100nm) is inserted between (La,Sr)MnO3 and cobalt or between two transition metals [2,3]. In this thickness range, associated to a diffusive transport, both positive and negative magnetoresistance have been observed. To understand this disparity between these results, it is necessary to probe the spin polarization at the ferromagnet/organic semiconductor interfaces. One approach is to study magnetic tunnel junctions composed of organic semiconductors. However very few reported on spin polarized tunnel transport [4]. This is partly due to the difficulties encountered when trying to elaborate a homogeneous nanometer thick organic layer over a micron size surface avoiding pinholes. Our solution is to reduce dramatically the size of the tunnel junction and use (La,Sr)MnO3 as a spin analyser [5]. We report on the fabrication and magneto-transport properties of (La,Sr)MnO3/Alq3/Co nanometer scale area magnetic tunnel junctions in which the few nanometer thick organic semiconductor Alq3 acts as a tunnel barrier.

(La,Sr)MnO3/Alq3 bilayers are first grown by a pulsed plasma deposition method developed at the ISMN [6]. Roughness is then characterized by atomic force microscopy. As expected the observed 20 nm peak to peak roughness (see figure 2) prohibits the elaboration of reliable micron size area nanometer thick tunnel junctions. To avoid short-circuits, as a prerequisite, we realize junctions over areas in the nanometer range for which the Alq3 thickness is kept homogeneous.

In order to create such nanometer size tunnel junctions, the fabrication is carried out using a combination of UV lithography and conductive tip AFM nanoindentation process where the tip-sample resistance is monitored in real time [7]. With this technique, we are able to control the section (about few tenth nm²) of the nanocontact. Moreover, by indenting further, we can also vary the organic tunnel barrier thickness. As a final step, cobalt is deposited into the nanocontact forming a magnetic tunnel junction enabling the study spin dependent tunnelling through the Alq3 layer.

We will present magneto-transport measurements performed on (La,Sr)MnO3/Alq3/Co nanojunctions. The thicknesses of the organic tunnel barriers are in the nm range and the junction areas are less than few tenth nm². The non-linear I(V) curves measured indicate the occurrence a tunnel transport through the organic barrier. On figure 2, we show a magnetoresistance curve obtained at low temperature. The high positive magnetoresistance (more than 200%) observed indicates that the magnetic and electronic properties are preserved at the (La,Sr)MnO3/Alq3 and Alq3/Co interfaces. We will discuss on the sign and amplitude of the magnetoresistance.

Theoretical studies on spin-dependent conductance in FePt/MgO/FePt(001) magnetic tunnel junctions.

Y. Taniguchi, Y. Miura, K. Abe, M. Shirai

Research Institute of Electrical Communication, Tohoku University, Sendai, Japan

Recently, extensive research activities have been devoted to non-volatile magnetoresistive random access memories (MRAMs) which exploit magnetic tunnel junctions (MTJs) as memory cells. When each cell-size is reduced in order to fabricate ultra-high density MRAMs, it is inevitable to improve the stability of the magnetization direction at each MTJ against thermal fluctuations at finite temperatures. A possible way to overcome this problem is adopting ferromagnetic materials with large magneto-crystalline anisotropy, such as L10-ordered FePt, as electrodes of MTJs. So far, a tunneling magnetoresistance (TMR) ratio of 18% has been observed at room temperature in the MTJ with an ordered FePt electrode and an amorphous Al-O barrier [1]. On the other hand, huge TMR ratios over 400% at room temperature have been reported for MTJs with use of single-crystalline MgO as a barrier material [2, 3]. Thus, it is worth while investigating the possibility to improve the TMR ratio by using the MgO barrier in the MTJs with FePt electrodes. In the present work we investigate electronic structures and spin-dependent transport properties of FePt/MgO/FePt(001) MTJs theoretically by using a first-principles ultra-soft pseudopotential method implemented in the quantum ESPRESSO code [4, 5]. The in-plane lattice constant is assumed to be identical with that of bulk FePt, 0.386 nm, and the interlayer separations in the MTJs are fully relaxed so as to minimize the total energy of the system.

First, we have calculated the electronic band-structure along the [001] direction of bulk FePt. As a result, we have found that the totally symmetric Δ_1 band crosses the Fermi level both in the majority and minority spin states. The minority-spin Δ_1 band is predominantly composed of Fe and Pt dz₂ orbitals at the Fermi level, while the majority-spin Δ_1 band is constructed from Fe and Pt pz and s orbitals. Since the Δ_1 band electrons predominantly transmit the MgO barrier [6, 7], huge TMR ratios can not be expected in the FePt/MgO/FePt(001) MTJs from the symmetry consideration of electronic band-structures in the bulk FePt and MgO. Next, we have investigated the energetically favorable atomic structure of the FePt/MgO(001) interface. By calculating the adhesion energy of the interface, we have found that the Fe-terminated interface, in which the Fe atom is located on top of the O atom, has strong bonding with MgO layer as compared with the other structures including the Pt-terminated interfaces. Moreover, the formation energy is lower for the Fe-terminated interface than that for the Pt-terminated interface. These results make a remarkable contrast to the FePt(001) surface; i.e. the Pt-terminated surface is more stable than the Fe-terminated surface. The formation of Fe-O bonding significantly contribute to the stability of the Fe-terminated FePt/MgO(001) interface. In fact, the Fe-O distance at the Fe-terminated interface is 0.22 nm, which is much shorter than the Pt-O distance, 0.26 nm, in the Pt-terminated interface.

Finally, we have investigated the tunneling conductance of FePt/MgO/FePt(001) MTJs. It is confirmed that the Δ_1 band predominantly contributes to the tunneling conductance for both majority-spin and minority-spin channels. The tunneling conductance as a function of in-plane components of electron wave-vector shows a sharp peak around the center of the two-dimensional Brillouin zone as usual. In the parallel magnetization configuration, the tunneling conductance via the majority-spin channel shows almost the same values for the MTJs with the Fe- and Pt-terminated interface. On the other hand, the tunneling conductance via the minority-spin channel depends significantly on the interface structure of the MTJ; i.e. the conductance for the Fe-terminated interface is two orders of magnitude smaller than that through the Pt-terminated interface. The remarkable

reduction of the tunneling conductance can be attributed to the scattering of dz₂ electrons in the interfacial Fe layer, where the atomic potential acting on Fe dz₂ electrons is altered from that in the bulk FePt due to the Fe-O bond formation. As the consequence, the TMR ratio evaluated for the MTJ with the Fe-terminated interface and five MgO layers exceeds 400%, which is in contrast to that of about 70% for the MTJ with the Pt-terminated interface. In conclusion, the Fe-terminated interface is more desirable for obtaining larger TMR ratio in the FePt/MgO/FePt(001) MTJs.

Fe-induced spin-polarized electronic states in a realistic semiconductor tunnel barrier.

M. Marangolo, F. Finocchi

INSP, Université Pierre et Marie Curie, Paris, France

Since a ferromagnetic metal (FM) provides a natural spin-polarized source, FM/semiconductor (SC) junctions have been extensively studied as integrated devices for spintronics applications. Whenever a Fm/SC interface is created, the electronic states on the metal side with energies comprised between the SC valence band top and the Fermi energy E_F decay exponentially in the SC. Called metal-induced gap states (MIGS), they are spin-polarized in the case of FM/SC junction. Their spatial behavior is crucial in spintronics, since it drives the tunnelling current. In this respect, it was shown that spin accumulation on the SC side can be obtained by means of a high enough FM/SC Schottky barrier or a tunnel barrier with resistance comparable to that of the semiconductor¹, thus remedying the resistance mismatch problem².

We consider the Fe/ZnSe(001) hetero-junction, which has been studied experimentally by our group to such a degree that it can be considered as a prototype of low reactive FM/SC interfaces. The mismatch between bcc Fe and ZnSe is quite small (1.1%). The interface is sharp without any loss of magnetic moment³. Chemical reactivity was not observed by spectroscopic measurements even if Zn atoms are released in the Fe film and Se atoms are detected on the growth front⁴. By first-principles calculations, we show that the formation of an intermixed Fe-Zn monolayer with interface Se-Fe bonding is favored with respect to ideal hetero-junctions. Since the averaged transmission polarization in the generalized Jullière model is indirectly linked to the interface polarization at the Fermi level and to the decay profile of polarized MIGS, we analyze by DFT calculations the influence of the structure of realistic interfacial phases on the spin polarization and on the electronic structure of the SC tunnel barrier.

The electronic DOS of ideal and intermixed hetero-junctions are shown in figure 2. Two main features are worth to be noticed:

- (i) close to the Fermi level, minority spin states dominate at the interface of ideal hetero-junctions, leading to a stronger spin polarization than in the intermixed interfaces (see Fig.2);
- (ii) the amplitude of the MIGS polarization within the semiconductor strongly depends on the interface geometry (see Fig.3).

In conclusion, a Fe-Zn intermixed buffer monolayer at the Fe/ZnSe(001) interface, which is here predicted to be energetically favored, dramatically affects the interface electronic structure. Intermixed junctions have little negative polarization at E_F , with respect to ideal Fe/ZnSe(001) interfaces. As far as spintronics is concerned, one important consequence is the strong reduction of the MIGS spin polarization inside the SC barrier, since spin injection depends on the competition between the majority and minority channels. The most favoured architecture for spintronics applications is the ideal Zn/Fe junctions; we are currently exploring the possibility that similar interfaces could be stabilized by low-temperature growth in Zn-rich environments.

Applications of organic semiconductors into spintronic domain, motivated by unquestionable advantage of weak spin-orbit coupling and hyperfine interaction, have been recently successfully demonstrated [1]. Magnetoresistive spin valves and magnetic tunnel junction based on archetypal organic materials Alq3 have been experimentally obtained [2,3]. In spite of the different mechanism, injection/transport for Spin Valves and tunnelling for magnetic tunnel junction, their performances are affected not just by the properties of their constituents but also by their metal/organic interfaces. Investigations on ferromagnet/organic interfaces are crucial in vertical devices, which typically include the deposition of a ferromagnetic contact on top of organic materials. Such deposition is by its nature critical: penetration of atoms, formations of complexes and cluster can be expected.

Morphology and disorder of ferromagnetic thin films, possible intermixing or interdiffusion at the interface may change the magnetic properties of the FM films and affect the intensity of spin valve effect. For this reason a detailed characterization of ferromagnetic metal/organic semiconductor heterostructures is necessary in order to understand and predict the device behaviour.

Hybrid spin valves with highly spin polarized manganite La2/3Sr1/3MnO3 and Cobalt as ferromagnetic electrodes and Alq3 as organic transport layer have been investigated (for experimental details see [4]). Room temperature operation have been obtained through the control of interfacial properties and interface engineering.

We present a full magnetic and morphological characterization of ferromagnetic films used as electrodes in spin valve devices and we correlate the results with the Spin valve device performance. 20 nm thick LSMO epitaxial films present a XMCD signal at room temperature indicating a good surface magnetisation. AFM investigations on 100 nm thick Alq3 films grown on epitaxial LSMO indicate a very smooth surface (rms 1 nm). A template growth of Co layers on top of organic semiconductor is observed. Magnetic characterization by MOKE and SQUID indicates the presence of a uniaxial anisotropy.

X ray magnetic reflectivity indicates that sharp Co/Alq3 interfaces are obtained in presence of a thin AlOx tunnel barrier (fig.1). An intermixing region of 2 nm has been measured. The tunnel barrier prevents the degradation of the interface and improves the quality of the SV effect reaching the room temperature operation.

The voltage controlled magnetization reversal has been proposed as a most energy saving writing method [1-4]. However, only few experimental results have been reported up-to-now [4, 5]. Here, we report voltage control of an in-plane magnetization at room temperature using a Schottky junction with a magnetic multilayer [2, 3].

In Fig. 1, schematic cross section of the sample is shown. N-type GaAs (001) layer ($n=5 \times 10^{17} \text{ cm}^{-3}$) was grown epitaxially on a GaAs substrate. Then Fe/Au/Fe/Au(001) magnetically coupled layers or Fe/Au (001) layers were grown on Ga-rich GaAs surface at room temperature. After the depositions, the metallic layers were cut into an oval shape ($600 \mu\text{m} \times 300 \mu\text{m}$) to form a Schottky diode.

The samples show typical diode characteristics with break down voltage of about 2 volts. The bottom Fe layer shows a large uniaxial and a small 4-fold in-plane anisotropy. The hard axis ([1-10]) saturation field is about 950 Oe for the 1 nm thick Fe layer whereas the easy axis coercive force is less than 20 Oe. The sample with $n\text{-GaAs}/\text{Fe}(0 \text{ nm} \leq d \leq 3.6 \text{ nm})/\text{Au}(3.4 \text{ nm})/\text{Fe}(1.5 \text{ nm})/\text{Au}(5 \text{ nm})$ structure shows clear oscillation of the interlayer exchange coupling strength as a function of the bottom Fe layer thickness, d [6]. Long lasting oscillation with 6 maxima reveals high electron coherency in the Fe layer. A Kerr ellipticity, η_K , hysteresis curve obtained for the $n\text{-GaAs}/\text{Fe}(0.85 \text{ nm})/\text{Au}(2.8 \text{ nm})/\text{Fe}(1.5 \text{ nm})/\text{Au}(5.0 \text{ nm})$ coupled layer is shown in Fig. 2 (a). Here, the external magnetic field was applied along to [010] direction (45 degree from the easy axis.). A hysteresis with three successive magnetic switchings is observed. Between the first and 2nd jumps, η_K continuously increases with increase of the external field because of a continuous rotation of the magnetization.

To observe a bias voltage effect, we modulated the bias voltage and detected the same frequency component in the η_K signal using a lock-in amplifier. Fig. 2 (b) shows a response to the bias voltage modulation, i.e. $d\eta_K/dV$ signal. Considerable $d\eta_K/dV$ signal was observed where η_K hysteresis shows the finite slope. For 1 Vp-p modulation the signal amplitude is about 0.3 % of the η_K . The origin of the effect can be either a change in the coupling strength [3] or the magnetic anisotropy [2]. To make this clear, we have examined the sample with a single Fe layer and obtained same kind of responses. Therefore, we tentatively conclude that the main contribution to the hysteresis modulation is a change in the in-plane magnetic anisotropy by the voltage across the Schottky junction. From symmetry, the electric field perpendicular to the film should affect to the perpendicular anisotropy. Here, we could control, however, the in-plane anisotropy by the perpendicular electric field. This may be attributed to the special symmetry of the GaAs (001) surface where an in-plane electric polarization may appear.

This result reveals a control of in-plane magnetization process by a voltage application and will be useful as a low energy consumption writing technique for the solid state magnetic memories.

The electric and magnetic properties of manganites are extremely sensitive to the concentration of free carriers. These properties can be varied not only by hole-doping the material, but also by designing a heterostructure where light or an externally applied electric field might effectively modulate the carrier concentration.ⁱ The presence of an interface represents, by itself, a significant perturbation of the electronic properties of perovskite manganites. The interface with a metal is known to affect the chemical and electronic environment of strongly correlated oxides, and can change basic electronic parameters, such as the Hubbard energy U , the electronic bandwidths, or the exchange energies.ⁱⁱ

We have widely investigated the effect of depositing a metal layer on ultrathin films of $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$ (LSMO) grown on SrTiO_3 (001) substrates (STO).ⁱⁱⁱ Magnetization curves taken with a SQUID apparatus on 4 nm thick epitaxial LSMO layers (Fig. 1) show a dramatic reduction of the Curie temperature upon deposition of 2 nm of Au (185 K); upon insertion of a 2 nm thick STO buffer layer the effect is only reduced but the decrease of T_C is still relevant (60 K). The latter finding, coupled to a detailed XPS investigation of the Au/LSMO interface showing negligible chemical reactions and interdiffusion, suggests that the effect might have an electrostatic origin. SQUID data on 8 nm thick LSMO films only show a small reduction of T_C : the effect is limited to layers with thickness slightly exceeding the “dead layer” typically developing at the LSMO/STO(substrate) interface (~3 nm). In thicker films, where the non-dead layer is thicker than the screening length (a few units cells in LSMO), the reduction of T_C is averaged out and tends to disappear.

Due to the strong connection between magnetism and transport in manganites, we have also investigated the effect of Au capping on the resistivity of ultrathin LSMO films. The resistivity vs. temperature is shown in Fig. 2: upon deposition of 2 nm of Au onto 4 nm of LSMO, we can see a strong decrease of the temperature T_p where the metal to insulator transition takes place ($\Delta T_p > 250$ K), in agreement with the observed decrease of T_C . Furthermore, the shift of T_p is accompanied by an extraordinary increase of the film resistivity at T_p , by four orders of magnitude. This is an unexpected result, that can be measured only due to the granularity of the thin Au film, avoiding a short circuit in the four probe measurements. In addition the $I(V)$ characteristics measured in the four probe configuration display high non linearity and negative differential resistivity, that indicate a non uniform resistivity in the film due to the phase separation of the LSMO induced by the granularity of the Au overlayer. As a matter of fact NMR measurements show a strong reduction of the double exchange signal from LSMO upon Au deposition, and SQUID detects a corresponding reduction of the macroscopic moment. The missing NMR and SQUID signals may be attributed to antiferromagnetic-insulating phases. In these separated films, then, conduction takes place via filamentary paths of conductive (ferromagnetic) manganite well separated by large regions of insulating (antiferromagnetic) LSMO.

These results indicates that the magnetic and electric properties of ultrathin LSMO films can be largely modified simply upon creation of a contact with a noble metal like Au. Detailed field effect experiments are currently performed in our laboratory to clarify if it is possible to produce sizable effects on magnetism in these films, in analogy to multiferroicity, or use these films as active channels in MOS-like devices.

The large tunnel magneto-resistance (TMR) measured in single-crystal Fe/MgO/Fe magnetic tunnel junctions (MTJs) [1] makes them serious candidates for applications. However, tailoring the electronic transport in these MTJs remains a challenge of great interest to improve their performances and our understanding on the tunneling mechanisms.

Several studies aimed at tuning the conductivities of the different tunneling channels responsible for the TMR, by inserting symmetry-dependant metallic barriers (Co or Cr films) [2,3]. Another possibility is to deal with interfacial chemistry between Fe and MgO. The interest of this approach was demonstrated in C doped MTJs.

We present here the first results on epitaxial MTJs with an oxygen doped Fe/MgO interface. Using X-ray photoelectrons spectroscopy (XPS), the amount of deposited O can be precisely controlled in the sub-monolayer regime (fig. 1). Moreover, scanning tunneling microscopy (STM) observations performed *in vacuo* provide atomically resolved maps of the Fe electrons tunneling efficiency (fig. 2). The adsorption kinetics monitored by XPS show the presence of two regimes, explained by the appearance of different O-related species in STM images (fig. 2 b). STM also evidences the O location on the hollow site of the Fe surface unit cell (fig. 2 c), a precious information for band structure *ab initio* calculations.

The precise control of both the O amount and the MgO thickness (growth assisted with RHEED intensity oscillations) allows us to investigate the properties of Fe/O/MgO/Fe MTJs at equilibrium (coupling between electrodes), and out of equilibrium (by biasing MTJs).

Biased O doped junctions preserve a large TMR (>90%) and exhibit interesting conductance features. In particular, the curves shown in fig. 3 seem to indicate that the interfacial O totally filters the low-bias Δ_5 tunneling channel (disappearance of the local maximum at zero bias).

Concerning the antiferromagnetic coupling between the Fe films observed at equilibrium in simple Fe/MgO/Fe multilayers (black curve in fig. 4), we find that the magnetization reversal of the *top* Fe film is strongly modified by the presence of O at the *bottom* Fe/MgO interface. The dependence of the coupling on the O coverage (brown curve in fig. 4) will be discussed by the light of the XPS/STM results.

An exciting area of materials engineering and related physics is the increased complexity and emerging new phenomena when building materials on the nanoscale level. Local interactions at the interfaces between two different materials with different properties play an important role due to spin, charge and lattice degrees of freedom interplay. Thin film deposition techniques allow to create model magnetic multilayers where important magnetic properties such as the magnetization, anisotropy and exchange parameters can be tuned. Important influence of Mo/Co interface on magnetic and magneto-optical properties of ultra-thin Co films was recently reported [1,2].

The purpose of this study has been to investigate the Mo/Co interface magnetic structure i.e. to determine: (i) if the Mo acquires the magnetic moment in the vicinity of Co and (ii) its magnetic coupling direction with the Co. In order to ascertain whether there is a surface magnetization state of Mo, samples with different Mo thickness were fabricated by MBE deposition technique. The crystallographic structure of the layers was monitored in-situ by RHEED, which showed that the in-plane directions relation Mo(110)/Co(0001) was satisfied for every sample. Samples were grown by a molecular beam epitaxy (MBE) system with the vacuum level in the range of 10⁻¹⁰ Torr. Sapphire Al₂O₃ wafers with the orientation (11-20) were used as substrates, on which a Mo buffer layer was deposited at 1000 deg C. Next Au buffer layer was deposited and annealed at 200 deg C for 15 min. All subsequent layers were deposited at room temperature. Co and Mo were evaporated from electron guns and Au from effusion cell at the rates lower than 0.5 Å/s. The multilayer samples were deposited with varying Mo layer thickness and constant Co layer thickness:

Al₂O₃/Mo/Au/(Co 25/ Mo d)x 20 /Pt

where d = 0.5, 1.0, 1.5 and 2.0 nm.

Standard thicknesses of Mo and Au buffer (b) and overlayer (o) were chosen as: dbMo=20 nm, dbAu=20 nm, doPt=8 nm. Cobalt film thickness d = 2.5 nm was chosen in the range where the in-plane anisotropy is present in such Mo/Co structures. The growth mode, crystalline structure and purity of the constituent layers were monitored in-situ by RHEED and Auger spectroscopy, respectively. Detailed structural analysis regarding constituent layers thickness, density and interface roughness was performed ex-situ by X-ray reflectivity. Multilayers magnetic structure was studied by polarized neutron reflectivity (PNR) and magnetisation measurements. Hysteresis loops and magnetization temperature dependence M(T) were measured using SQUID magnetometer. The PNR measurements were carried out on the PRISM instrument at Laboratoire Léon-Brillouin, CEA-Saclay, at 10 K and with an in-plane external magnetic field of 1.0 T in order to magnetically saturate the samples. The wavelength used was 0.43 nm and the Q-range was from 0.05 to 2.2 nm⁻¹. The spin-up and spin-down reflectivities (R⁺, R⁻) of the all samples were measured. The data have been corrected for the polarization efficiency. The least squares fitting of all the reflectivity data (X-rays and neutrons) was made using the SimulReflec software [3]. For the scattering lengths of X-rays and neutrons and absorption cross sections the tabulated values were employed.

From the PNR data of four Mo/Co samples the Mo and Co magnetic moments have been determined. In all the Mo/Co multilayers it was found that a magnetic moment has been induced in the Mo and that the Mo layer is antiferromagnetically coupled to the Co layer. The product of the molybdenum layer thickness by its moment is almost constant for all studied Mo/Co samples,

which demonstrates that only a top slab of molybdenum layer close to the interface with Co is magnetically active. The thickness of this slab is less or equal to 4 ML and the induced molybdenum magnetic moment higher or equal to 0.8 mB/at (thinner magnetically active slabs imply larger Mo moments). It seems that the interface roughness is further reducing the number of Mo next neighbours, distorts the bond lengths and angles and between 3 to 4 monolayers of Mo acquire a magnetic moment. Also, the lattice strain occurring at the interfaces during epitaxial growth of hcp Co on Mo bcc metal can influence the ordering at the interface. Large magnetic moments for V have been already reported for the systems of Fe/V [4] and Co/V [5] but this is the first experimental evidence of an induced magnetic moment in Mo.

Noncollinear Surface Spin Density of equiatomic NiMn alloy on Cu(001).

C. Gao¹, A. Ernst¹, A. Winkelmann¹, J. Henk¹, W. Wulfhekel^{1,2}, P. Bruno¹, J. Kirschner¹

1. Max Planck Institute of Microstructure Physics, Halle (Saale), Germany; 2. Physikalisches Institut, Universität Karlsruhe (TH), Karlsruhe, Germany

The surface spin density of the antiferromagnet is important in determining the exchange interaction across the antiferromagnet/ferromagnet interface. The atomic scale understanding of the antiferromagnetic surfaces is, however, very limited due to the limited resolution of the traditional techniques. In this joint experimental and theoretical investigation we show by spin-polarized scanning tunneling microscopy (Sp-STM) that the surface spin density of NiMn films is non-collinear in space (a variation of the direction of the spin polarization with the coordinates) and energy (a variation of the direction of the spin polarization with the energy of the electrons). The very reason for this effect is the broken surface symmetry, as is supported by first-principles electronic-structure calculations.

Chemically ordered Ni₅₀Mn₅₀ grown on Cu(001) has a structure similar to that of the respective bulk (L1₀), with Ni and Mn atomic sheets oriented perpendicular to the Cu(001) surface [1]. A careful analysis of the atomically resolved STM image shows that in addition to the c(2x2) chemical ordered arrangement of the Ni and Mn atoms, a p(2x2) reconstruction was present due to the slightly different coordinates of every second Mn (Ni) atom of the surface layer. The layer thickness and the coordinates of the surface atoms were determined quantitatively with the LEED-IV measurements and simulations.

The Sp-STM measurements were performed in the differential magnetic mode at 300 K [2]. A ferromagnetic CoFe-SiB ring whose magnetization can be switched periodically was used as STM electrode. A major advantage of this method is that the ring has a well-defined direction of in-plane spin sensitivity, determined by its shape. Further, the signal is of purely magnetic origin. This technique is therefore well suited for investigating alloy films.

Two different spin patterns were observed at positive bias voltages (from 0.1 V to 0.5 V) as shown in Fig. 1. One displays a checkerboard structure (domain 1) whose unit cell coincides with the c(2x2) chemical unit cell (3.6 Å x 3.6 Å) while the other exhibits parallel lines (domain 2), the separation of which equals that of adjacent Mn sheets (3.6 Å). The two spin patterns reflect two magnetically equivalent, orthogonal structural domains distinguished by the orientations of the Mn sheets either along [100] or along [010]. The two patterns appear differently in the spin-resolved STM image because the projections of their spin polarizations onto the spin-sensitive direction of the STM differ reflecting the non-collinearity of the spin polarization in real space. As the bias voltages change from positive to negative (-0.1 V), the pattern in domain 1 changes from high contrast c(2x2) to weak contrast p(2 x 2) cells. In domain 2, the ordered feature disappears at negative voltages. The change of the spin unit cell in domain 1 from c(2x2) to p(2x2) indicates a change of the direction of the spin polarization of individual atoms as a function of the energy of the electrons which can be defined as a non-collinearity of the spin polarization in the energy domain.

The observed non-collinear surface spin density in both space and energy domain was attributed to the symmetry breaking at the surface due to the surface reconstruction. This mechanism requires spin-orbit interaction as a means to couple the orbital degrees of freedom (which are sensitive to the atomic displacements) to the spin degrees of freedom (which determine the spin polarization of the tunnel current). To support the above explanation of non-collinearity, scalar-relativistic and fully relativistic first-principles electronic structure calculations were carried out for 6ML-NiMn films on Cu(001) within the local spin-density approximation to density-functional theory, using

Korringa-Kohn-Rostoker methods for layered systems. Both the unreconstructed and the experimental geometry were considered in the self-consistent calculations. For NiMn bulk, the collinear antiferromagnetic phases are energetically preferred to the ferromagnetic phase. The magnetic moments of nearest-neighbor Mn atoms in the film couple antiferromagnetically whereas those of second-nearest Mn atoms couple ferromagnetically. The total energy of the reconstructed p(2 x 2) cell (with atomic positions taken from the LEED-IV analysis) is lower than that of the ideal c(2 x 2) cell, thus supporting the LEED-IV analysis. The spin resolved density of states of the surface atoms shows that close to the Fermi level, Mn shows high (low) spin polarization above (below) the Fermi level in agreement with the experimental observations.

Room temperature ferromagnetism in pristine and Mn-doped ZnO thin films.

*H. Nguyen*¹, *E. Chikoidze*², *Y. Dumont*²

Theorists have predicted that ferromagnetism (FM) at high temperature could be obtained in various semiconductors if we substitute metal ion by Mn and having a high concentration of holes in those systems. Actually room temperature FM was experimentally observed in many transition-metal (TM)-doped semiconducting oxides under the thin film form. However, the phenomenon is not exactly as what theory supposed, because the compounds are found to be n-type.

Room temperature FM was observed in pristine ZnO thin films grown on Al₂O₃ substrates. The FM in this compound unlikely originates from oxygen vacancies but from other kind of defects. Magnetization of very thin films is much larger than that of the thick films indicating that defects must be located mostly at the surface and/or the interface between the film and the substrate.

Data on Fe:ZnO and Mn:ZnO films show that a TM doping does not play any essential role in introducing the magnetism into ZnO. However, in the case of Mn doping, the magnetic moment could be enhanced only slightly. Hall effect measurements reveal that the incorporation of Mn does not change the carriers type (both ZnO and Mn:ZnO films are n-type), but decreases the carrier concentration and increases Hall mobility, resulting in more resistive Mn:ZnO films. Since no anomalous Hall effect was observed, one must conclude that the observed FM is not due to the interaction between the free-carrier and the Mn impurity, but other effects. Studying on very thin films of ZnO would elucidate the issue if there were any modification of the ordering at the surface/interface.

Tailoring the magnetic properties of all-ferromagnetic artificial FeCu(111) alloy thin films.

The magnetic properties of a given material are strongly related to its crystalline structure. Among others, aspects as important as the magnetic moment per atom, the type of magnetic long-range order (ferro- or antiferromagnetic), or the coercive field are extremely sensitive to any modification of the interatomic distances or the chemical environment. Iron-based structures are an example of this subtle interplay between structural and magnetic properties, and have consequently attracted extensive attention. A great variety of properties has been predicted if the structure and lattice parameter of Fe could be changed from their bulk properties [1]. In this presentation we will show the growth of artificial $\text{Fe}_x\text{Cu}_{1-x}$ [111] thin films and the influence of thickness, concentration, and temperature on the electronic and element-resolved magnetic properties.

Iron-copper alloys of these otherwise immiscible elements have to be synthesized artificially by using far-from-equilibrium producing techniques. FeCu alloy thin films were grown at room temperature codepositing simultaneously Fe and Cu onto a Cu(111) substrate precovered with a surfactant Pb layer. The latter reduces the film roughness and, at the same time, prevents the segregation of the two components by reducing the atom mobility on the surface layer [2]. Element-resolved magnetic measurements were performed in remanence by x-ray magnetic circular dichroism (XMCD) at the Fe and Cu $L_{2,3}$ absorption edges at the UE56/2-PGM2 beamline at BESSY.

Figure 1 shows total electron yield absorption spectra XAS (top) for positive and negative helicity (black and red curves, respectively) and the difference, the magnetic dichroism XMCD (bottom), at the Fe and Cu $L_{2,3}$ absorption edges of a 37 monolayers (ML) $\text{Fe}_{55}\text{Cu}_{45}$ film on Cu(111). The induced magnetic moment of the Cu atoms is also clearly visible in the XMCD spectra. Fe and Cu moments are aligned parallel, as can be seen from the identical sign of the Fe and Cu dichroism. The evaluation of the magnetic moments by sum rule analysis reveals an Fe spin moment smaller than that of bulk Fe. The induced moment at the Cu atoms is slightly larger than that found in artificial FeCu(100) alloys [3].

A non-ferromagnetic behavior is found up to ~15 ML of alloy, and above 120 K. For thicker films, a low spin phase ferromagnetic behavior is found at room temperature. The evaluation of the magnetic moments by sum rule analysis reveals the magnetic moment of both the Fe and Cu atoms increases as the thickness of the alloy increases (see Fig.2 (a)). These changes are related to the structural fcc-bcc transformation that takes place with increasing thickness (see Fig.2 (b)). The structural change in the alloy is reflected in the change of the XAS line shape just above the Cu- L_3 edge, where a two-peaked feature converts to a single peak when the thickness of the alloy increases. Additionally, an enhancement in intensity for the alloy film is observed at the Cu- L_3 edge, ~934 eV photon energy. Since the XAS spectra reflects the Cu unoccupied density of states above the

Fermi edge, this can be judged as manifestation of an enhanced number of unoccupied Cu d -like states in FeCu with respect to pure Cu metal.

Low temperature measurements show that the fcc-bcc structural transition can also occur by decreasing the

temperature. Additionally, this structural transition is delayed when the concentration of the Fe in the alloy is smaller. Our findings demonstrate that it is possible to tune at will the magnetic moments of the iron, and therefore the Cu, atoms by combining the appropriate thickness and chemical composition of the alloy.

Epitaxial hetero-structures based on Magnetite, Fe_3O_4 , have attracted considerable interest due to its half metallic ferromagnetic nature, high Curie temperature (838 K) and presence of a metal-insulator transition at 120 K, (Verwey transition). Magnetic properties of epitaxial $\text{Fe}_3\text{O}_4/\text{MgO}$ (100) hetero-structure are found to be strongly influenced by their method of preparation, presence of intrinsic defects (antiphase boundaries, APB). Presence of APBs led to non saturation of magnetization in high magnetic fields and superparamagnetic behavior for ultrathin (<5 nm) films. Here, we report a detailed magnetization studies on well characterized epitaxial Fe_3O_4 thin films (2-20 nm thickness) grown on MgO (100) using oxygen plasma molecular beam epitaxy (MBE) technique. We find that the films exhibit a ferromagnetic behavior down to 2 nm thickness and possess magnetic moments greater than that of bulk magnetite. Our results are in direct contrast to previously accepted dead layer interface model or a super-paramagnetic behavior for ultra thin films of magnetite [1,2]. In order to find the origin of enhanced magnetic moment, we considered various possibilities such as contribution from Fe_3O_4 -MgO interface, surface terminations and defects (cationic and anionic). From detailed spin-polarized density functional theory based calculations of Fe_3O_4 -MgO interface, we estimate that the spin moments of the Fe ions in the vicinity of the Fe_3O_4 -MgO interface are marginally enhanced but these changes are insufficient to explain the observed results. Orbital moment contribution for the surface Fe atoms also turn out to be quite small. The non-compensation of spin-moments between the tetrahedral (A) and octahedral (B)- sublattices inferred to be the main factor contributing to the observed enhanced magnetic moment.

Chromium is a transition metal with a rich variety of magnetic properties that has been the focus of many studies. It is an itinerant antiferromagnet (AFM) in the bulk and presents an incommensurate spin density wave. In thin films the coupling with the substrate transforms this AFM spin-density wave (SDW) from an incommensurate to a commensurate one. Furthermore, the current interest in spintronics has been partially initiated by the discovery of the giant magnetoresistance effect in Fe/Cr multilayers. Further progress in this area depends on atomic level control in the manufacturing of spintronic devices.

Surprisingly, structural and magnetic characterizations of ultra-thin Cr films on W(110), a common substrate for thin metal films because of its resistance to alloying, are scarce. Most studies actually focus on the thick-Cr regime, where the surface is assumed to be a proxy of bulk Cr. One basic question is whether ultra-thin films of Cr on W(110) present magnetic ordering, and if so, what kind. The problem is challenging because few methods are capable of detecting antiferromagnetism in such thin layers. Recent ab-initio calculations indicate that a monolayer might be magnetic. Here we present a combined low-energy electron diffraction intensity-versus-voltage (LEED IV), spin-polarized (SP)-STM, and ab-initio theory study with the aim of obtaining a thorough understanding of the atomic and magnetic structure of Cr films a few atomic layers thick on W(110). LEED IV is the classic tool for determining the interlayer separation of the first few atomic surface layers with errors in the 0.01-0.02 Å range. A satisfactory comparison of LEED with ab-initio density functional theory (DFT) is also a mature approach and, in general, is considered the gold standard for surface structure determinations. Well-converged spin-polarized DFT calculations usually predict surface relaxations in good agreement with experiment even for magnetic materials. Finally, SP-STM is one of the few techniques able to measure local antiferromagnetic order on surfaces. By depositing a ferromagnetic film on the tunneling tip, images with atomic contrast related to the magnetic structure of the surface can be acquired. The sensitivity of the tip to either in-plane or out-of-plane surface magnetic moments can be tuned by applying magnetic fields.

The first-principles calculations predict a very different surface relaxation for antiferromagnetic and non-magnetic Cr films. Only in the antiferromagnetic case is the calculated relaxation compatible with that determined by LEED IV. This strongly suggests that films of one, two and three atomic layers of Cr on W(110) have antiferromagnetic short-range order. As seen in the figure, SP-STM data confirm this finding: The Cr monolayer on W(110) shows characteristic stripes along the [001] direction due to the antiferromagnetic order of nearest-neighbor Cr atoms. Additionally, the SP-STM data of the Cr monolayer reveal a periodically varying magnetic amplitude that peaks every ~7.7 nm. On thick Cr(110) films the signature of an incommensurate spin density wave, existing in two different orientations, is found. We also compare the LEED IV and ab-initio relaxations of bare W(110) and bulk-like Cr(110) surfaces.

In many of the most intriguing new concepts of contemporary magnetism such as the reversal of the magnetization by spin-polarized electron currents, it is of crucial importance to understand the interaction of spin-polarized electrons with a ferromagnetic material. Due to spin-dependent scattering the spin polarization vector of the interacting electrons is expected to change. We measured this spin motion, comprising an azimuthal precession and a polar rotation around the magnetization direction of the ferromagnet, in the past both in transmission and in reflection geometry on simple ferromagnetic systems [1-3]. Of even more interest both from the fundamental and from the practical point of view are quantum-well structures in which standing electron waves are formed. The existence of such quantum-well states is at the origin of a number of different oscillatory phenomena in thin films, such as the oscillatory exchange coupling between two ferromagnetic layers separated by a non-magnetic spacer layer.

Here we report on spin-polarized electron reflection experiments in which the electron-spin motion is studied in spin-dependent quantum-well structures. Oscillations of the electron-spin motion due to quantum interference are observed in the system Au/Co(001) as a function of the Au-overlayer thickness. The reflectivity as well as the spin-motion data can be well interpreted in terms of a simple Fabry-Pérot interferometer model. We discuss the influence of the spin-dependent reflectivity, the inelastic mean free path, the scattered electron intensity contribution, and the growth mode on the behaviour of the electron-spin motion within the interferometer model.

Advanced Technology Research Laboratories, SHARP CORPORATION, Tenri, Japan

Introduction

Thermally assisted magnetic recording is one of key concepts to achieve high density magnetic recording beyond 1 Tb/inch². There have been several experimental reports concerning the thermal assisted recording [1-6]. Especially in the field of the hybrid magnetic recording, near field optics has been adopted as a nanoscale thermal source [4-6]. In particular, we have proposed a surface plasmon and magnetic field applicable synchronously hybridized (SMASH) head that generates magnetic field and surface plasmon at nanosized region. We have demonstrated the capability of the SMASH head for the near-field assisted magnetic recording [4]. Several groups have proposed hybrid magnetic heads combined with an optical waveguide or an optical fiber unit [5-6]. However, precise optical alignment with the near field generator and a light source remains difficult. There is no tangible proposal how to hybridize the head with a laser device.

In this paper, we show a monolithically-fabricated hybrid head with a GaAs-based laser diode for the near field assisted magnetic recording. The hybrid head is composed of a laser diode and a generator of the near field and the magnetic field. We confirm localization of the near field on the generator on the hybrid head using near field scanning optical microscope (NSOM).

Experimental

Figure 1 shows a mock-up assembly image of the monolithically-fabricated hybrid head. The size of hybrid head is less than that of a femto-slider. The components of the laser diode and the generator are located in the center of trailing edge of the slider. The near-field and magnetic field generator consists of double layered metals and the upper layer has a 200 nm width slit. The lower layer is deposited on the SiN insulator layer on the GaAs substrate. The slit produces a bottleneck structure. The magnetic field is mainly generated around the bottleneck structure by feeding current through the metal double layers. The laser diode is monolithically fabricated on the substrate, where the position of laser diode's active layer is adjusted to that of the generator as the emitted laser beam effectively enters into the bottleneck structured portion.

Results and discussion

Figure 2 shows a scanning electron microscopic image observed from the air bearing surface side around the generator on the slider. The generator with the bottleneck structure is located in front of the high mesa laser ledge. The precise optical alignment between the generator and the laser beam has been accomplished using monolithically fabrication process. Figure 3 shows the NSOM image around the bottleneck region of generator. Near field is locally generated on the top and bottom edge of the bottleneck structure, where the near field intensity is designated as bright part. We confirmed that the near field intensity exponentially decreases with the scanning z-height of the SNOM probe.

Exploiting far- and near-field optics to develop energy efficient transducer for heat-assisted magnetic recording.

Recently, it became clear that the conventional magnetic recording schemes are coming to end because of the superparamagnetic limit. Heat-assisted magnetic recording (HAMR) may have potential to extend the data densities to 10 Terabit/in². In order to record information, HAMR will use not only magnetic but also thermal energy. Therefore, a recording media with substantially higher anisotropy could be utilized. In one of the proposed implementations, a laser beam in the near field, co-aligned with the recording field, heats up a local region to the temperature close to the Curie point. The key challenge in this implementation is to develop a near-field transducer capable of delivering over 50 μ W into a spot diameter of 30 nm. The traditional fiber schemes are barely capable of producing 10 nW. To resolve this issue, a laser diode could be placed with the emitting edge only a few nanometers away from the recording media [1]. The light can propagate through a nano-aperture on the surface of an aluminum-coated emitting edge.

The transducer is required to focus light into a spot with a diameter less than 50nm. Knowing that classical optics is diffraction limited to approximately half the wavelength, an approach to combine both: far-field and near-field optics will be employed to focus light not only to a nanoscale spot, but also to superiorly enhance its power efficiency to deliver sufficient power to elevate the disk temperature. The foundation for employing far- and near-field optics arise from current limitations in collimating laser diode beams caused by exceedingly high beam divergence at the facet of commercial semiconductor lasers. This novel device will firstly focus light into a diffraction limited spot on a metallic thin film where nanoscale apertures acting as focusing antennas will focus the light further to spots of less than 50nm diameter and more than 500nW of power. Figure 1top exemplifies how the first plano-convex lens will collimate the beam, then get focused to a diffraction limited spot in the order of a few microns on the air-bearing surface of the contact forming lens by the second plano-convex lens. It has been numerically modeled that such focusing method improves the power transmission efficiency by at least two orders of magnitude relative to defining the nanoapertures directly on a metalized laser facet. The design of so called “aperturless” probes to conceive an adequately high energy throughput near-field system remains to be a decisive element. Numerical simulations have indicated evident dependence between the aperture geometry and its transmission efficiency and focusing capabilities (figure 1bottom).

Design and characterization of a media thermal stack for confining lateral thermal heat flow.

D. Karns, G. Ju, A. Itagi, B. Lu
Seagate Technologies, Pittsburgh, PA

Abstract

We report on a pump-probe tool, referred to as the scanning pump-probe spin stand, which enables the measurement of the lateral thermal profile created in a medium of interest by a static or scanning incident focused laser beam. This tool enables the relative quantization of lateral diffusivity for experimental samples. The tool utilizes a 405 nm diode laser focused through an objective lens with a numerical aperture of 0.85 for probing the thermal profile in the medium. This is a similar configuration to the Blu-Ray and HD-DVD configurations. Using experimentally measured material properties, good agreement between experiment and modeling was achieved for the complete structure of an exemplary high density optical storage media. The media stack consists of a substrate, heat sink layer, seed layer, recording layer and a protective overcoat. Effects of layer thickness and materials on the lateral thermal flow have been studied. Non-static cases have been examined and the thermal stack optimized to assure thermal confinement and minimal thermal spread in the sample during motion. With an optimized stack design the thermal profile measured by the scanning pump probe spin stand is close to the minimum expected for both the static and non-static cases, indicating strong lateral thermal confinement and good heat sinking into the substrate material.

Experimental results

The heat sink thickness series of disks has the following structure, CuX with a vertical thermal conductivity of 250 W/(mK) on glass with a thermal conductivity of roughly 1 W/(mK) and a high Curie temperature recording layer. The disk without a heat sink produces a narrow thermal profile with a FWHM of only ~450 nm, and very small thermal tails roughly 3% of the peak signal at 1 μ m from the peak signal as shown in figure 1. The narrow profile is a result of the low thermal conductivity and thus strong lateral thermal confinement in the recording medium. When a thin, 50 nm, heat sink is added the heat is allowed to spread laterally. The disk with a heat sink thickness of 50 nm produces a considerable amount of thermal spread in the medium. As the heat sink becomes thicker, it allows the heat to be conducted away from the recording medium and reduces thermal spreading in the recording medium. The data did show the general form expected from modeling.

The heat sink is needed to allow thermal diffusion away from the magnetic recording layer when the disk is spinning. Otherwise, a teardrop thermal profile will form and the trailing edge will be extended and yield a poor thermal gradient. This effect can be observed in figure 2.

To reduce the thermal spreading induced by the heat sink material with a high thermal conductivity a seed layer is utilized. The seed layer is designed to allow heat flow from the recording medium to the heat sink but not back into the recording medium from the heat sink. This should produce a narrow FWHM and minimize re-heating effects far away from the thermal source known as tails or shoulders. The data shown in figure 3 represents the FWHM of the measured thermal profile versus the seed layer thickness. It is clear that the thicker seed layer is effectively reducing the measured FWHM. The minimum measured FWHM is 540 nm, which is smaller than the measured value of 720 nm from the reference disk without a heat sink or a seed layer.

The last step is to utilize all of the knowledge gained and fabricate a disk that maintains thermal confinement when spinning. The heat sink should be sufficiently thick with a high thermal conductivity. Also, the seed layer must be properly designed to alleviate lateral heat flow. The measured

thermal profile for the disk spinning at ~11 m/s remains symmetric and the FWHM remains approximately 486 nm.

Conclusions

A XY scanning pump probe spin stand was constructed. This system can be used to measure the lateral thermal profile created in a medium by an incident pump laser by utilizing a probe laser. The probe laser is modulated and fed into a lock-in amplifier to increase the system sensitivity. The medium can also be measured as a static or spinning disk. This allows the thermal bloom due to medium motion to be measured. A recording layer can show good thermal confinement without a heat sink. However, if the medium is spinning a heat sink is required to conduct heat away from the recording layer and minimize the tear drop effect. However, lateral thermal bloom can occur for a heat sink that is not thick enough. A design of seed layer can be optimized to reduce the effects of lateral thermal bloom when media is static and spinning.

Domain structure in TbFeCo/FePt-grains composite film and Cu doping effect on Curie temperature of FePt grains.

A. Itoh¹, A. Tsukamoto¹, F. Chino², S. Iwase², Y. Sano², K. Okayama²

1. Dep. of Electronics and Computer Science, College of Science and Technology, Nihon University, Funabashi, Japan; 2. Dep. of Electronics, Graduate School of Nihon University, Funabashi, Japan

Thermally assisted magnetic recording (TAMR) can solve fundamental problems concerning thermal fluctuation and write capability in magnetic recording. Although the advantages of TAMR in increasing areal density, it has implementation issues such as optimization of thermal profile and the magnetic head. Rausch et al. reported¹⁾ that there exists an optimal alignment between them, which minimizes the transition length, and parameter effects by using a systematic thermal Williams-Comstock recording model (explicitly included thermal term : $dH_c/dT \times dT/dx$). Moreover, grain size dominates transition noise in present granular perpendicular media.

In this study, we report a micromagnetic modeling analysis of the composite magnetic recording media, consisting of FePt granular under layer that act as a domain pinning of TbFeCo continuous layer and yield smooth transition boundaries. TbFeCo is well known as magneto-optical recording media and thermal property such as T_c and dH_c/dT is rather controllable by adequate tuning of composition ratio. Therefore, we also performed thermal characterizations of FePt nano-particles by Cu doping.

1. Micromagnetic simulation of composite magnetic recording media

We performed 3-dimensional LLG simulations for estimating domain shapes in TbFeCo/FePt-grains composite film. Two models containing different grain diameter d and spacing s were employed. For overcome the recording density of 1 Tbit/inch², d and s have to be decreased until comparable scale with the domain wall width W_d , and it causes difficulty to predict the domain structure. At the Model 1 ($d = 5$ nm, $s = 3$ nm) period of each grains p is nearly equal to W_d and Model 2 ($d = 4$ nm, $s = 2$ nm) is higher density model. Fig. 1 shows initial state of magnetization of the film (Model 2).

Fig. 2 shows the temperature dependence of domain diameter D_d at the boundary of TbFeCo/FePt, at the surface of TbFeCo, respectively. The material parameters are estimated from experimental reports and calculation with mean field approximation. Simulated result shows magnetic domain could be formed on all the cases. Well isolated and exchange decoupled FePt grains, pinned and defined the domain shape of the continuous layer. Moreover, we found that $D_d < 23$ nm (it is suitable at 1.3 Tbit/inch²) could be formed even under the condition of $p < W_d$. In addition, for the simulation, with an exchange break between the granular and continuous layers, the initial domain shrunk and disappeared. The introduction of a granular layer pins the magnetization of the exchange-coupled layer. Furthermore, it is confirmed that domain shape is smoother at the surface of TbFeCo layer. This smoothening of domain shape contributes to a reduction of the medium noise caused by magnetization transition due to magnetic irregularities or magnetic clusters.

2. Cu doping effect on Curie temperature T_c of FePt grains

We investigated the effect of Cu doping to T_c within FePt particles (FePt, $T_c = 770$ K) prepared by Rapid Thermal Annealing (RTA) method²⁾. Cu doped Pt/Fe film was fabricated by RF magnetron sputtering onto thermally oxidized Si substrates. First the FeCu and then the Pt layers were deposited, and then RTA was done by using a 2 kW lamp in a vacuum chamber at a pressure of 9×10^{-4} Pa. The heating rate was 100 K/sec.

As-deposited double-layer Pt/FeCu (total film thickness is 3.8 nm) was continuous films, and after 773 K at 1 sec. RTA, well isolated particles formed. Fig. 3 shows the typical results of temperature dependence of Coercivity determined from magneto-optically (Kerr ellipticity) measured perpendicular hysteresis loops. It is clear that T_c successively and sensitively reduced by increasing the amount of Cu doping. Moreover, advantageously large value of dH_c/dT (around 160 Oe/K) was appeared in each case.

Magnetic properties of amorphous magnetic film on self-assembled convex pattern.

N. Iwata, D. Honda, Y. Murakami, A. Takahashi

Advanced Technology Research Laboratories, SHARP CORPORATION, Tenri, NARA, Japan

Introduction

Several fabrication methods for bit patterned media are proposed, for example, combination of self-assembled molecules and dry etching [1], nanoholes and electrodeposition [2]. However, these methods require drastic change of the conventional media manufacturing process. We introduced a newly developed self-assembled convex pattern method as an underlayer of amorphous TbFeCo thin film media. The convex pattern can be easily fabricated using conventional sputtering and reactive ion etching (RIE) equipments. TbFeCo is one of the hopeful candidates for near field assisted magnetic recording [3] because of its high perpendicular anisotropy and low Curie temperature, but it is necessary to reduce the exchange coupling force at the magnetic domain boundaries to achieve the area densities of over 1 Tbits/inch². In this paper, we report magnetic properties and magnetic domain size to confirm the effect of convex pattern.

Experiment

Firstly, we deposited Ta on a Si substrate using a sputtering machine with RF bias applied. Fabricated dots had the periodicity around 25 nm on the Si substrate. After Ta deposition, Si substrate was reactive-ion-etched in fluoride gas atmosphere using the Ta dots as an etching mask. Atomic force microscope (AFM) images after the RIE is shown in Fig.1. The convex pattern after RIE had the periodicity of around 28 nm, the height of around 15 nm and the maximum angle to the substrate plane at the steep region of the convex curve was 75 degrees. A TbFeCo film and a Ta capping film were deposited onto the convex pattern and magnetic properties were evaluated using a vibration sample magnetometer and a magnetic force microscope (MFM).

Results and discussions

Fig.2 shows the normalized remanence coercivity (H_r) of the fabricated samples on a flat Si substrate (a) and on the convex pattern (b) both with a 50 nm-thick TbFeCo film as a function of applied field angle (θ) from the direction normal to the substrate plane. The TbFeCo on the flat substrate (a) indicated monotonous increase showing almost the same tendency of the theoretical domain wall (DW) type curve. On the other hand, normalized remanence coercive force on the convex pattern (b) decreased with similar tendency of the Stoner-Wohlfarth model (S-W) from 0 degree to 45 degrees, and it showed further decrease in larger angles. These results indicate the magnetization reversal modes are different between sample (a) and sample (b), and the TbFeCo on the pattern has regions whose easy axes are rather close to parallel than to normal to the substrate plane.

Fig.3 shows MFM images of the 50 nm-thick TbFeCo film on the convex pattern. The small magnetic domains are observed whose diameters are around 50 nm.

Summary

Reduction of magnetic domain size was confirmed in the amorphous TbFeCo film deposited on the self-assembled convex pattern. The reduction is attributed to the change of the anisotropy direction and the decrease of exchange coupling force at the steep region of the convex curve. This result indicates the possibility of realizing amorphous film patterned media which can be preferable for near field assisted magnetic recording.

Comparison of Dual and Thermal Gradient Recording Methods for Thermally Assisted Magnetic Recording.

F. Akagi, T. Matsumoto, M. Igarashi
Hitachi, Ltd., Tokyo, Japan

Introduction

Thermally assisted magnetic recording (TAR), which combines thermo-magnetic writing with magnetic reading, is a promising system for achieving a high areal recording density [1,2,3]. TAR is classified into some recording methods depending on the dimensions of the light spot and head-field. In this study, we compared the write performance of the dual gradient recording method (DGRM) and the thermal gradient recording method (TGRM). The DGRM combines a small light spot with a head-field with a sharper field gradient. The TGRM combines a small light spot with a large head-field.

Calculation Method

The recording process was calculated using the Landau-Lifshitz-Gilbert equation, which adds a stochastic thermal field to an effective field [4]. The output signal and the noise were calculated using a Fourier transform of the averaged magnetization in the track-width direction. The magnetic characteristics of the medium at 300 K are shown in Table 1. The temperature dependence of the anisotropy field (H_k) was calculated using a Brillouin function [5] and the Curie temperature was 550 K. The thermal profile was assumed to be a Gaussian distribution, the half width of which was 80 nm and the temperature increased by 250 degrees. The head-field (H_h) for DGRM was calculated with single-pole-type head and that for TGRM was a uniform field.

Results and Discussion

Figure 1 shows the MH major loops for H_k of 17 kOe and 25 kOe. The sweep rate was 625 Oe/ns, which was equal to the recording speed. The nucleation field (H_n) intensity for H_k of 17 kOe was 7 kOe and that for H_k of 25 kOe was 12 kOe. If the magnetic field that is stronger than H_n is applied to the medium, magnetizations will begin to reverse without thermal. Figure 2 shows the comparison of recorded magnetization patterns at 1000 kfci between DGRM and TGRM. The head-field intensity was 12 kOe. The magnetization patterns of DGRM for both H_k were clearly observed. The magnetization pattern of TGRM for H_k of 17 kOe was not observed, but that for H_k of 25 kOe was clearly observed because the uniform head-field, which was stronger than H_n for H_k of 17 kOe, erased the recorded magnetization pattern. Figure 3 shows the comparison of the magnetization patterns at 122 kfci between DGRM and TGRM. It was found that the magnetization pattern for DGRM was clearly observed, but there were reversal magnetizations in the bit for TGRM because a uniform head-field was applied to the recorded bit, which caused the reversal magnetizations.

Conclusion

It is cleared that a head-field of TGRM strictly affects recorded magnetization patterns in comparison with DGRM.

Heat assisted magnetic recording (HAMR) is a promising technological innovation which utilises a laser heat source to reduce the coercivity of recording media so that magnetic information can be written in a reliable way. To achieve a sufficiently low coercivity requires substantial heating of the recording media, often in the vicinity of the Curie temperature. At such high temperatures conventional micromagnetic models cease to accurately represent the physical situation and new approaches are required to understand magnetic effects near the phase transition. However, the intention with HAMR is also to increase the magnetic data density through the use of high anisotropy materials, such as FePt and CoPt. Such an increase in data storage density presents a problem in itself, arising from very significant finite size effects as data densities approach 1 Terabit per square inch. Thus HAMR provides a significant challenge to our understanding and knowledge of magnetic phenomena at nanoscopic sizes and near the Curie temperature.

In this digest we use an atomistic Heisenberg approach to investigate the reversal process for 10 nm FePt grains with heat assisted writing. The room temperature coercivity of the grains was assumed to be 5 Tesla, correlating with approximately 50% L_10 ordering. Due to the small size of the grains, they also have a reduced Curie temperature of 680 K compared to around 750 K in Bulk. The atomistic simulations properly take into account the thermal fluctuations of the magnetisation length and direction which are not included in conventional micromagnetic models. The reversal mechanism is a statistical process and has been investigated by repeatedly writing a single grain with varying laser power. The effects of laser heating are modelled with a pseudo three-dimensional discretised heat transfer model. The cooling process is simulated by moving the laser away from the target grain as would occur in an actual device with revolving media. This results in a cooling time of around 350 picoseconds from T_c to room temperature. In order to accurately reflect the present situation at the device level, a maximum external applied write field of 0.8 Tesla has been used. Due to the high anisotropy, simulations of the temperature dependence of the anisotropy field show that the write field is ineffectual below a temperature of 640 K. This leads to the concept of a critical cooling time, which defines the length of time where the external field is greater than the anisotropy field.

We find that in order to reliably reverse the grain, the maximum temperature of the grain must exceed the Curie temperature, which coincides with a change in the reversal mechanism. Specifically, instead of precessional reversal, where the magnetisation vector rotates around the anisotropy axis, the length of magnetisation passes through zero and reforms in the opposite direction, a process known as linear reversal. This arises from the fact that the mean reversal time of the precessional mode is longer than the critical cooling time, so precessional reversal is thus unlikely to occur. Cooling through the Curie temperature, however, has no such limitation since the magnetisation can reform in the correct direction due to the large susceptibility at T_c . A plot of the time dependence of the magnetisation for a single reversal is shown in Fig. 1. The data shows the rapid decrease in magnetisation when the laser is turned on, and the linear change in the z-component of M as the system is cooled through the Curie temperature.

Plot of time dependence of the magnetisation of a single 10 nm FePt grain. The external applied field of 0.8 Tesla is in the negative z-direction. The data show a rapid decrease in the length of the magnetisation, as well as a linear change in the z-component.

Modeling of thermally-activated switching of single phase, exchange-coupled and graded media.

1. POMT, Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain; 2. Vienna University of Technology, Vienna, Austria

The superparamagnetic limitation of the current magnetic recording media has stimulated an extensive search for alternative ideas. Among those, the exchange-coupled composite (ECC) media has been suggested [1,2] as a possibility to decrease the necessary recording field without deterioration of the thermal stability. The graded media [3] has a further advantage in decreasing the nucleation field while maintaining the same energy barrier as the ECC one. Most of the extensive work on the media optimisation has been performed using the zero-temperature micromagnetic framework. In this case, the energy barrier is normally evaluated through the minimum energy path separated the two minima in the static many-body magnetisation landscape. The questions related to the change of energy landscape with temperature, related to thermodynamics such as the free energy and entropy are normally ignored, therefore, limiting the problem to relatively low temperatures.

In the present work, we use the Langevin dynamics approach, integrating the stochastic Landau-Lifshitz-Gilbert equation to simulate the switching properties of the single-phase, ECC and graded media. The atomistic approach with simple cubic lattice with $a=0.33$ nm, for simplicity has been used. To simulate the most favorable situation we assume an elongated grain with 24nm length and 1.5×1.5 nm base dimension. The hard media phase had an anisotropy constant $K_{\text{hard}}(T=0) = 3.6 \cdot 10^7$ erg/cc. The soft media phase was considered to have an anisotropy constant $K_{\text{soft}}(T=0) = K_{\text{hard}}/6$ and the graded media - the variation of the anisotropy constant following the quadratic dependence [4]. Fig. 1 presents results on the switching times of three ferromagnetic grains: single hard phase, ECC and graded media, as a function of the inverse temperature. The switching process of the graded media occurs clearly much faster than other alternatives. Assuming the Arrhenius-Neel law with static magnetisation landscape approach, this gives a reversal constant for the single grain $8 \cdot 10^{-14}$ s, and much larger value for the graded media $4 \cdot 10^{-12}$ s. The thermodynamic averaging of magnetic properties of different grain types also suggests that the energy barriers depend differently on temperature for different media.

Furthermore, we have also investigated the switching process for ECC grains with different exchange values. This introduces different dependences of magnetisation on temperature in both soft and hard grains. Different situations: high T_c soft/low T_c hard and low T_c hard /high T_c soft have been considered.

Fig.1 The switching time of single phase, ECC and graded grain as a function of the inverse temperature. The exchange parameters $J=6.53 \cdot 10^{-14}$ erg and the magnetisation value $M_s(T=0) = 600$ emu/cc was considered to be the same in all cases.

Application of plasmon resonances to all-optical magnetic recording.

1. ECE Department and UMIACS, University of Maryland, College Park, MD; 2. Laboratory for Physical Sciences, College Park, MD

It has been recently demonstrated [1] that magnetization reversals can be achieved in a reproducible way by using only circularly polarized laser pulses, that is without applying any external magnetic fields. The direction of magnetization reversals is controlled by the helicity of light. It is believed that these magnetization reversals occur due to the combination of the local laser heating of magnetic media close to the Curie temperature and the simultaneous action of circularly polarized light as a magnetic field with the direction parallel to the light wave vector. Furthermore, right- and left-handed circularly polarized waves act as magnetic fields of opposite directions. The performed experiments [1] have demonstrated femtosecond magnetization reversals of 100nm spots on magnetic media.

The purpose of this paper is to theoretically and numerically demonstrate that plasmon resonances in metallic nanoparticles can be efficiently used for all-optical magnetization reversals of nanoscale spots of magnetic media. These magnetization reversals can be achieved by focusing of light at nanoscale and, at the same time, preserving its circular polarization. The above two conditions can be simultaneously achieved by exciting specific plasmon modes in metallic nanoparticles with uniaxial symmetry. Our analysis has been based on the treatment of plasmon resonances as an eigenvalue problem for specific boundary integral equations [2-5]. By using this mathematical machinery, we have been able to identify two identical and ninety degree-shifted in space plasmon modes for several promising nanoparticle designs. Such two plasmon modes have the same resonance frequency and can be simultaneously excited by the incident circularly polarized light resulting in dramatic nanoscale enhancement (focusing) of this light. The two particular designs that have been extensively studied are spherical and cylindrical silver nanoshells on dielectric substrates. Nanoshells are very attractive because, by controlling their thickness, plasmon resonances can be shifted into the 800 nm – 1000 nm wavelength region. In this region, the ratio of the real part to imaginary part of silver dielectric permittivity achieves its maximum values. This results in very strong local enhancement of the incident light intensity. It is worthwhile to note [2-5] that resonance frequencies and plasmon resonance fields depend on nanoparticle shape, but they are scale invariant with respect to particle dimensions, provided that these dimensions are appreciably smaller than the free-space wavelength. This scaling property can be utilized for scaling plasmon modes to various storage densities. The numerically identified plasmon modes for spherical and cylindrical shells with silicon cores are illustrated in Figures 1 and 2, respectively. In the paper, the detail exposition of the theoretical and numerical aspects of our analysis of circularly polarized plasmon modes will be presented. The coupling of these plasmon modes to incident laser radiation as well as their time-dynamics of excitation and dephasing will be discussed as well.

Narrow Track Confinement by AC Field Generation Layer in Microwave Assisted Magnetic Recording.

Y. Tang, J. Zhu

Electrical and Computer Engineering, Carnegie Mellon University, Pittsburgh, PA

In present perpendicular magnetic recording system, the track width is mainly decided by the width of main pole in the writer. Consequently, keep scaling down the writer dimension is necessary for achieving high track density. However, when the width of main pole is less than 60 nm, the strength of magnetic field beneath the pole tip is significantly degraded, which will cause writability issues in recording. Meanwhile, single domain is preferred in the ultra narrow pole when the current is turned off, which will induce severe remanent field erasure. Considering the two reasons above, it is a challenge to writer designs for track density beyond 400 TPI.

We have proposed microwave assisted magnetic recording (MAMR) based on the ferromagnetic resonance phenomena¹. Based on present trailing shielded pole head, a perpendicular spin torque driven oscillator² is inserted between the trailing shield and main pole, which will generate localized ac field at microwave frequency regime. Our simulation indicated, with the presence of a high frequency AC field, media can be switched by a write field well below the media coercivity. A major benefit in this novel recording scheme is high K_u magnetic material can be used as recording media. Hence, we can keep squeezing the grain size and increasing the recording areal density. On the hand, since both ac field and head field are needed for media switching, the recording track width depends on the overlap area of the ac field and head field. A narrow track can be obtained by only shrinking the dimension of ac field generation layer (FGL).

In our simulation, the recording fields from a trailing shielded pole head is calculated by FEM. The width of main pole is 120 nm and spacing between shield and pole is 50 nm. The maximum head field on the media is assumed 12 kOe. The thickness of ac FGL is 15 nm. The maximum ac field on the media is assumed 3 kOe. And the ac field frequency is 42 GHz in recording. The height and width of ac FGL are identical. The recording performances on a single hard magnetic layer are studied. The size of media grains is 5 nm and thickness is 10 nm. The crystalline anisotropy field of media is 10 kOe and 30 kOe for conventional recording and MAMR, respectively. In MAMR, the offset between the ac FGL and main pole is optimized to maximize on-track signals. Figure 1 shows the recording patterns at 1000 KFCI for the conventional perpendicular recording and MAMR. In the conventional recording, the curvature of transitions at the track edges is significant, which leads to large ATE and low track density. For MAMR with 100 nm width ac FGL, narrow and straight transitions are obtained due to the well confined overlap region of ac field and head field. And track width is obvious decreased by shrinking the FGL width from 100 nm to 50 nm. The quantitative magnetic write width (MWW) is calculated from the cross track profiles of on-track signals in frequency domain, which is shown in figure 2. For a 120 nm writer with 50 nm FGL, the track density reaches 451 TPI. Since the curvature of transitions is almost eliminated in MAMR, the SNR will also be improved due to the missed side signals in the read back process.

LLG Simulation of Microwave Assisted Switching in Isolate Particle.

M. Igarashi¹, Y. Suzuki¹, H. Miyamoto¹, Y. Maruyama², H. Fukui², Y. Shiroishi²

1. Hitachi, Ltd., Kokubunji, Japan; 2. Hitachi Global Storage Technology, Odawara, Japan

As recording bit density of hard-disk drives (HDD) becomes higher, volume for a bit becomes smaller, requiring larger media anisotropy energy to keep thermal stability and exceeding the physical limit of conventional magnetic head writability. Microwave assisted recording with a microwave generator of spin torque has recently been proposed as one of the promising candidates of next generation recording technology [1].

However, our preliminary study revealed that required field for switching in a single domain particle with microwave [2] is not so small as the case reported. This suggests that a certain important factor in the recording media is missed at the single domain particle.

In this work, intra-grain exchange coupling effect was investigated to be the factor. A sub-grain is with the large exchange field when the direction of the sub-grain magnetization is different from the exchange coupled neighbors. If a certain sub-grain meets a resonance condition and its magnetization starts rotate on, a large high frequency exchange field will affect resonance of the adjacent sub-grains and finally entire magnetic particle. We have investigated the switching characteristic assisted by microwave for an isolated particle composed of sub-grains using the LLG (Landau Lifshitz Gilbert) simulation.

A hexagonal prism grain with a diameter D of 8.5 nm and a height t_{mag} of 12.0 nm was used to simulate an isolated single grain. The grain was divided into two sub-grains in the direction of the height (z-axis). In each sub-grain, the magnetization rotates coherently and interacts with the neighbor by the exchange coupling. The easy axis of each grain was in the direction of the height. The value of the uniaxial perpendicular anisotropy energy K_u was assumed to be 13.5 Merg/cc ($H_k=30$ kOe). The time evolutions of the magnetizations in the sub-grains were calculated by solving the LLG equation. The switching time was investigated up to 3ns with changing strength of the microwave, its frequency, and the external field.

Figure 1 shows the time dependences of the z-components of the sub-grains at AC-field of 5 kOe, AC-frequency of 50 GHz, and the external field of 6 kOe. Both sub-grain magnetizations show almost similar behavior with small vibration and do not switch up to 0.1ns. When the time exceeds 0.1ns, the difference of the both becomes remarkable and each sub-grain switched around 0.2ns. It should be noted that large exchange fields have effected to the other sub-grains from 0.1ns to 0.2ns.

Figure 2 shows the switching field at AC-field of 6 kOe as a function of the frequency for a magnetic particle separated into two parts (Twin) along with a single domain particle. The switching field is defined as a minimum field where the switching can be completed within 3ns after the fields application. The switching field decreases with increasing the AC-frequency below an optimum AC-frequency f_{opt} , above which the switching field increases with increasing the AC-frequency. The f_{opt} increases with increasing the angle between the external field and the magnetization easy axis θ_h . On the other hand, the switching field slightly depends on the AC-frequency and its value is almost equal to the Stoner-Wohlfarth field.

Thus a large effect of microwave assistance is achieved through exchange coupling between the sub-grains in an isolate particle.

Hyperfine field distribution in the Heusler compound Co_2FeAl probed by ^{59}Co NMR.

S. Wurmehl¹, J. T. Kohlhepp¹, H. Swagten¹, B. Koopmans¹, C. Blum², B. Balke², G. H. Fecher², C. Felser²

1. Applied Physics, Eindhoven University of Technology, Eindhoven, Netherlands; 2. Institut für Anorganische und Analytische Chemie, Johannes Gutenberg-University, Mainz, Germany

The Heusler compound Co_2FeAl is reported to occur in various structures ranging from the completely ordered $L2_1$ to the completely disordered $A2$ structure type. The difference in $B2$ and $A2$ structured Co_2FeAl thin films was already reported by Inomata *et al.* [1] using the spin echo nuclear magnetic resonance (NMR). NMR provides a tool to obtain the local environment by measuring the resonance frequencies and consequently probing the local hyperfine magnetic fields, revealing next neighboring shells of the NMR active atoms. This method is thus suitable to study the local structure of Heusler compounds [2]. Inomata *et al.* [1] observed a line splitting due to Co atoms experiencing a random distributions of Fe and Al in thin films of Co_2FeAl .

In this work, NMR is used to probe the structure of Co_2FeAl bulk samples. It will be shown that NMR is a very suitable tool to uniquely study the local structure of magnetic materials by probing the direct local environments of the active atoms and resolving next neighboring shells. A study of bulk samples provides the unique possibility to verify the intrinsic generic structural properties of a certain material.

As shown in figure 1 (a,b), the ^{59}Co NMR spectrum of the bulk Co_2FeAl samples (as-melted) revealed a splitting into main and sub-lines. These main lines originate from the distribution of Fe and Al in the neighbouring shells of the ^{59}Co nuclei. Each main resonance line can be attributed to a certain distribution of Fe and Al in the first shell of the ^{59}Co nuclei in agreement with the results of Inomata *et al.* [1]. A complete intermixing of the Fe and Al atoms leads to a structure type different from $L2_1$, the $B2$ structure. From a crystallographic point of view, a basic requirement of the $B2$ structure is an entire random distribution of Fe and Al of the Wyckhoff 1a position. The random distribution of Fe and Al ($B2$ type) is described by a binomial distribution, revealing the probability $P(n,x)$ for a particular environment of the form n Fe atoms + $(8-n)$ Al atoms in the first shell of the Co central atom. A comparison between the fitted relative areas of the resonance lines (grey line in fig. 1) with the probabilities given by a random distribution of Fe and Al demonstrates that as-melted Co_2FeAl bulk samples mainly exhibit a $B2$ type structure with contributions of a $L2_1$ type structure of about 10%. This $L2_1$ contributions were not apparent in the NMR spectrum of Co_2FeAl thin films [1].

The structure of the bulk samples can be changed by annealing (figure 1 (c,d)). The NMR spectrum of a bulk sample annealed at 1300 K consists of several main lines with an underlying sub-structure similar to the NMR spectrum of an as-melted sample. However, the main lines are less resolved after annealing and seem to merge. It was not possible to sufficiently fit the main lines of the spectrum of the annealed sample using only the Gaussian lines expected for a pure $B2$ type ordering or a mixture of $B2$ and $L2_1$. These observations point to a loss of the high degree of order as shown for the as-melted sample. A satisfactory fit was obtained by implementation of an additional broad resonance line. Interestingly, the additional very broad line exhibits the characteristic resonance frequency and width of a completely $A2$ ordered Co_2FeAl sample as shown by Inomata *et al.* [1]. It seems that annealing at 1300 K leads to a mixture of $B2$ and $A2$ contributions. According to Balke *et al.*, annealing at 1300 K leads to Co_2FeAl samples with a mixture of $A2$ and $B2$ contributions [2], thus supporting our NMR results.

Summarising our results, additional contributions of structural phases as $L2_1$ and $A2$ can be excluded to cause the sub-lines. However, a random distribution of Fe and Al may not only affect the composition of the first coordination shell of the ^{59}Co nuclei but may also affect the composition of higher shells. Thus, the sub-structure is related to different higher shell environments of the ^{59}Co nuclei. This sub-structure of the resonance lines was not resolved in ^{59}Co NMR spectrum of thin Co_2FeAl films [1], pointing to a more pronounced long range order in the bulk samples than in thin film samples.

This NMR study demonstrates the possibility to further improve the degree of order in Co_2FeAl , which may lead to high TMR ratios when implemented in magnetic tunnel junctions.

Shedding light on magnetoelastic coupling and magnetostriction at an atomic level.

S. Pascarelli¹, M. Ruffoni¹, A. Trapananti¹, O. Mathon¹, Y. Joly², R. Pettifer³, M. Pasquale⁴, A. Magni⁴, C. P. Sasso⁴, F. Celegato⁴, E. Olivetti⁴

The local character and chemical selectivity of X-ray Absorption Spectroscopy (XAS) has been used to address the complex problems of magnetoelastic coupling and magnetostriction at the atomic level. This has been made possible thanks to recent developments in the field of synchrotron radiation based methods, which have enabled the measurement of femtometer atomic displacements [1]. In principle any reproducible subtle distortion of the local structure induced by an external perturbation can now be investigated and quantified. Phenomena such as magnetostriction, electrostriction, piezoelectric or magnetic effects, elastic compliance or thermal expansion may be investigated from an atomic point of view, so that we can understand which atomic movements are responsible for the macroscopic effect that we observe.

Up to now, experimental input relied essentially on macroscopic quantities where the important atomic information is averaged out over different chemical bonds, defects, etc. Being able to be not only “local” but also “chemical selective” opens an enormous potential for the study of complex and disordered systems.

Here we will focus on ferromagnetic materials, and investigate magnetoelastic coupling and magnetostriction at the atomic level. Since the spin system in a ferromagnetic system is coupled to atomic displacements, due to the spin-orbit interaction, and since the static portion of this interaction results in a shift in the equilibrium atomic positions, we can now detect the effects of magnetization on the local structure [1]. Magnetoelastic coupling, i.e. the dependence of Magneto-Crystalline Anisotropy (MCA) energy on lattice strain, is the subject of intensive theoretical and experimental work nowadays because it governs the behaviour of technologically interesting ferromagnetic systems for high-density magneto-optical storage and magnetostrictive applications. The understanding of magnetostriction, and its theoretical description, still remains a great challenge because it is difficult to determine the dependence of MCA energy on lattice strain. In this respect, direct measurements of local strain values, as well as their evolution with pressure, can give a fundamental input to gain physical insight into this complex problem.

One of the first problems we addressed is the investigation of local atomic displacements induced by anisotropic magnetostriction in FeCo and how these are affected by a modification of the volume of the unit cell. Here magnetoelastic coupling is found to favor enhancement of atomic displacements with decreasing volume, contrary to expectations based only on the commonly accepted “stiffening” of bonds with compression [2]. State-of-the-art ab-initio electronic structure calculations of the evolution of magnetocrystalline anisotropy energy with tetragonal strain in FeCo are found capable of predicting correctly even such tiny effects, where the energies in play are of the order of the μeV . This kind of information, obtained through the combination of experiment and theory, is fundamental to be able to guide the search for materials with improved properties.

The second problem that we are now looking at is trying to apply these methods to elucidate the atomic origin of the giant magnetostriction observed in rare-earth transition metal compounds. It is well known for example that in rare-earth-Fe₂ (RE-Fe₂) compounds, the huge anisotropy of the 4f electron cloud, the high moment, and the high Curie temperature, lead to large magnetostriction. In these systems, when the orientation of the magnetic moment of the 4f shell is rotated with

respect to the crystallographic axes by an external magnetic field, it is assumed that the anisotropic 4f charge density is rigidly co-rotated and displacements of RE atoms from their equilibrium position could occur. Internal distortions in TbFe₂ were predicted 40 years ago [3] but to date have not yet been detected. In the attempt to identify and eventually quantify RE atomic displacements in RE-Fe₂ compounds, we have initiated a XAS study on amorphous films of TbFe₂, DyFe₂ and TbDyFe₂ at the Fe K and RE L₃ absorption edges. To detect bond strain induced by magnetostriction the sample is magnetically saturated under a magnetic field applied on the plane of the film. We then measure changes in photoelectron scattering path length induced by local atomic distortions arising only from the rotation of the magnetic field, using XAS in a differential mode [4]. Preliminary results show that the large differential XAS signal observed at the RE L₃ edge can be qualitatively and quantitatively described using ab-initio fully relativistic multiple scattering theory, and can be directly associated to the polarization of the RE 4f and 5d orbitals due to the very strong spin-orbit interaction. This effect is therefore not directly related to the displacement of the RE, but only to a distortion of the charge density around the RE. These calculations also show that we may have the sensitivity to the displacement of the RE in the [111] direction, and a first estimate gives a value of $\sim 0.013 \text{ \AA}$, in agreement with ab – initio electron theory that predicted that the aspherical 4f charge density may produce large magnetostrictive strains [5].

Detection of magnetic reversal at a DW pinning site in Ni80Fe20 nanowires using concurrent Magneto-Optical Kerr Effect (MOKE) and electrical measurements.

H. T. Zeng, D. Read, D. Petit, L. O'Brien, E. Lewis, A. Jausovec, R. Cowburn
Physics, Imperial College London, London, United Kingdom

The ability to measure both the magnetic and electrical transport properties of ferromagnetic nanostructures in-situ with the same instrument is highly desirable in current nanomagnetism research, enabling resistance changes to be easily correlated with an associated change in magnetization. This change in resistance can then be used to infer the presence of different magnetic configurations, such as the type of domain wall present in the nanowire (1). We have modified a commercial MOKE magnetometer to be able to position 16 electrical contacts with a pitch of $125\mu\text{m}$ (Fig. 1) for concurrent transport measurements of our samples.

Using this setup, we have measured the anisotropic magnetoresistance (AMR) due to transverse domain walls (TDWs) in 10nm thick, 180nm wide Ni80Fe20 nanowires. These were fabricated into an L shape using electron beam lithography and thermal deposition, with a symmetric double outward notch located along the horizontal arm acting as a pinning centre for the TDWs (Fig.2). The geometry of the L-wire allows an external field to create TDWs in the corner, and the magnetization of the horizontal arm can be reversed by propagating this wall along the length of the wire. With a double outward notch, a potential well for the TDW is introduced (2), so a field higher than the propagation field must be applied to move the TDW past the notch and to switch the rest of the wire. We call this the transmission field, and it has been measured by MOKE to be ± 78 Oe for the sample presented here. This is appreciably lower than the saturating field required resetting the wire magnetization into the single domain state (± 162 Oe). Four-terminal magnetoresistance measurements taken across the pinning site on the same sample enable us to detect the presence or absence of a TDW at the trap, since the magnetization of the DW core lies orthogonal to the current flow direction, and contributes to a lowering of the resistance. The field values corresponding to transitions in the AMR signal are shown to match the switching fields obtained from the MOKE measurements (Fig. 3).

We also found that the amplitude of the DW AMR signal decreases as the external field pushing the DW at the notch approaches the transmission field value. This is believed to be a consequence of thermally activated magnetization reversal (3), numerical simulations of the DW depinning process were carried out using the OOMMF code.

Fig. 2: SEM image of the double outward notch between two Au contacts, for an inter-contact spacing of 800nm.

Fig. 3: (i) MOKE data showing switching at ± 78 Oe through the notch, corresponding to transmission. (ii) Plot of AMR signal and x field component as a function of time for the L-wire. In the first half of the field cycle (field at 0.1Hz), the wire is reset and no DW is trapped at the notch. A field pulse at 5s creates a DW in the corner, and this is propagated into the notch at 6s, where it remains until 8.7s under a constant x field. The x field values at these transitions are 36 Oe and -77 Oe, indicating pinning and subsequent withdrawal of a TDW at the notch. The prominent dips in AMR are a result of pulses along the y-axis used to reset and inject the DWs, which gives rise to a global AMR effect.

Material selective sensitivity of magneto-optical Kerr effect in NiFe/Au/Co/Au periodic multilayers.

Magneto-optical (MO) effects have been recently extensively applied to study thin-film magnetic phenomena as magnetic anisotropy, magnetization reversal, interlayer coupling, and magnetization dynamics [1]. Main advantages of the MO effects are their high near-surface sensitivity, nondestructive character, and possibility to measure all components of the magnetization vector in the frame of the magneto-optic vector magnetometry [2]. Depth sensitivity of MO effects was systematically studied by Traeger [3] and Hubert [4] using modeling of the MO effect from a buried thin MO film in a non-magnetic surrounding. Separation of polar MO signal from films in different depth was presented by Ferre [5] and Hamrle [6] in the case of Co films separated by Au spacer. Depth sensitivity of longitudinal Kerr effect in Fe/Cr/Fe structure was demonstrated by Nyvlt [7].

In this paper, we propose to use a selective sensitivity of magneto-optical Kerr effect for separation of signals from different materials in a periodic multilayer. The method of material selectivity is demonstrated on the magnetostatically coupled periodic multilayers [Ni₈₀Fe₂₀(2 nm)/Au(2 nm)/Co(0.8 nm)/Au(2 nm)]₁₀ prepared by sputter deposition on a silicon substrate [8].

A. Theoretical background

Magneto-optical selective sensitivity described in this paper is based on differences between magneto-optical and optical parameters of different MO materials, which results in different phases of MO complex response. Figure 1 shows modelled magneto-optic contributions from particular layers of the structure in the MO complex plane. The coordinates correspond to the polar MO Kerr rotation and ellipticity. Normal incidence and the light wavelength of 640 nm is used in the model based on Yeh's matrix formalism. Deeper layers contribute less to the overall signal due to the light absorption. This corresponds to points close to the origin. Total MO response of Co and NiFe can be obtained in reasonable approximation by summing contributions of all Co and NiFe layers, respectively. Different azimuths of Co and NiFe in the complex plane gives possibility for separation of their MO signals.

B. Experimental demonstration

Similarly as for depth sensitivity, different methods for MO signal separation can be proposed: (i) adjustment of wavelength of inspected optical beam, (ii) phase adjustment of magnet-optic ellipsometer using Babinet-Soleil compensator, and (iii) numerical linear combination of measured Kerr rotation and ellipticity. In this study, we demonstrate separation of Co and NiFe contribution by linear combination of measured Kerr rotation and Kerr ellipticity. In the separation we use a matrix relation between the vector consisting of Kerr rotation and ellipticity and the vector of magnetic signals from Co and NiFe. Matrix inversion enables to evaluate the weight coefficients for the linear combinations. We expect that the Co film has its polar component close to saturated value everywhere except for low magnetic fields. Figure 2 shows separated MO hysteresis loops of Co and NiFe. From the obtained hysteresis loops we deduce that magnetization of Co reverses from up to down direction via a domain structure changes. However, in the case of NiFe the perpendicular field forces the magnetic moments to rotate toward the field direction. Without field, due to mag-

netostatic coupling between Co and NiFe layers [8], the magnetization of NiFe is inclined by the angle of approximately 20 degree from the in-plane direction.

Magneto-optic contributions of Co and NiFe layers are shown.

Magneto-optical contributions of particular Co and NiFe layers in the multilayer periodic system are shown in the complex MO plane. Points on the lines close to the origin correspond to layers from the top of the structure. Different directions of the Co and NiFe contributions gives possibility for material selective sensitivity.

Magnetic images of a surface crack on a heated specimen with the use of an area type magnetic camera with high spatial resolution.

J. Lee¹, J. Hwang²

1. Department of Information and Communication Engineering, Chosun University, Gwangju, South Korea; 2. Department of Information and Communication Engineering, Graduate School of Chosun University, Gwangju, South Korea

When a metal or electric conductor is placed in an electromagnetic field, the distribution of the magnetic field becomes distorted around the object as a result of the direct current input, magnetizer, alternative current, eddy current, pulsed current, or residual magnetization. Cracks in the structure can be detected and evaluated by analyzing the distorted electromagnetic field. Hence, measuring and displaying the quantitative electromagnetic field in real time is an important methodology for a quantitative non-destructive evaluation (QNDE). The novel micro-array method of Hall sensors, as shown in Fig. 1, was proposed in previous research [1]. That array method enabled 2-dimensional magnetic field measurement with high spatial resolution with the use of the simplified connections. A wide range of magnetic fields could be measured quantitatively with high spatial resolution.

This paper proposes a non-destructive testing (NDT) method with the use of an area type magnetic camera and the above-mentioned micro-array method, in order to detect cracks on a specimen at high temperatures. Fig. 1 (b) shows the principle used to obtain the magnetic images of a surface crack on the heated specimen, with the use of an area type magnetic camera with high spatial resolution. Distilled water has a boiling point of 100 °C at atmospheric pressure. Therefore, the Hall sensor array, which is submerged in the distilled water, can be protected from an external high temperature of several hundred degrees centigrade until the container, which is filled with distilled water, is broken. If the Hall voltage of each Hall sensor changes with respect to the external magnetic field at the boiling point of the liquid, the crack can be detected in a high temperature environment with the use of the magnetic camera submerged in the liquid, as proposed in this paper. The ferromagnetic specimens, which are 100×200×5 mm in size and each have slits as shown in Fig. 2, were used to verify the proposed NDT method with the use of the high spatial magnetic camera in a high temperature environment. Fig. 3 shows the magnetic images of each specimen at 170 °C. Magnetic intensity increases with respect to the width and depth of each crack. Also, the integrated values of maximum and minimum $\partial V_{\text{RMS}}/\partial x$ have a strong relationship to the width and depth of the crack, as shown in Fig. 4.

Magnetostriction of Iron at Low Temperatures Observed with X-Ray Diffraction.

E. Arakawa, N. Aizawa

Physics Dept., Tokyo Gakugei University, Koganei,, Japan

Variations of iron magnetostrictive coefficient $\lambda^{y/2}$ in the direction of easy-axis magnetization at low temperature region have been reported [1]. A minor maximum at 200 K was observed with a strain gauge extensometer [1]. No minor maximum was, however, found at that temperature region with the strain gauge extensometer and a capacitance dilatometry [1]. Theoretically, $\lambda^{y/2}$ of ferromagnets should fall monotonically to zero with increasing temperature [2]. For measurements at the low temperature region, the coefficients obtained by the strain gauges were said to be less reliable because of magnetoresistance [3]. Correction of low-temperature contraction to values observed with a strain gauge was in the order of tens of micron. Recently, a technique with X-ray diffraction to observe magnetostriction was improved [4]-[6]. As it observed a d -space displacement of crystalline specimen, a correction of specimen position due to the low-temperature contraction was relatively easy. As it was a non-electric technique, a correction of the magnetoresistance for a probe was not concerned. Therefore, reliability of the X-ray technique was not changed principally even if at such low temperature region. The purpose of this study was to determine the values of iron $\lambda^{y/2}$ with the X-ray diffraction technique at the low temperature region.

The experiment was performed on beamline BL15B1 of the Photon Factory at KEK, Japan. Photon energy of incident π -polarized X-rays to a specimen in a transverse configuration of magnetization was set to a resonant energy at Fe K absorption edge, 7.111 keV, 1.744 Å [4]. The specimen was a single crystal of iron, 99.94+%, Monocrystals Co. It was a disk of 6.0 mm diameter and 2.0 mm thick. Flat plane of the specimen was (110) and polished sub-micron. The [001] axis of the specimen was vertical, parallel to the magnetic field of an electromagnet and perpendicular to the scattering plane. In the transverse configuration, a quantitative magnetostriction of perpendicular component to the saturation magnetization could be determined and a saturation of magnetization could be confirmed during cyclic magnetization [4], [5]. We set the specimen cool down from room temperature to 100 K and warm up to 300 K with a cryostat. To determine $\lambda^{y/2}$, we measured rocking curves of 220 diffraction intensity at zero magnetic fields and observed magnetic field dependence of the diffraction precisely.

Temperature dependence of $\lambda^{y/2}$ observed was shown in Fig. 1. In the analysis, a magnetostrictive volume change was neglected [4]. The minor maximum at 200 K was not obvious in this experiment. All measurement time in this experiment was approximately four days, which included time to wait thermal equilibrium and time to adjust specimen position and angle. Reported experimental and theoretical results were also plotted in Fig. 1 [1], [3], [4], [7]. Curves of the magnetoelastic coupling coefficient $B^{y/2}$ were converted from $-\lambda^{y/2}c^y$, where c^y was an elastic constant, for cubic symmetry [1], and plotted in Fig. 2. In the conversion, c^y was taken from Rayne and Dever [8], [9].

Enhancement of magneto-optical Kerr signal from the nano-structure by employing anti-reflection coated substrate.

C. You, D. Kim

Department of Physics, Inha University, Incheon, South Korea

Detection of the magnetic dynamics of the ferromagnetic nanowire and nanodot is an important research subject, because of its rich physics [1] and technical importance [2]. Magneto-optical Kerr effect (MOKE) is one of the promising technologies for detecting magnetic signal from a ferromagnetic body due to its sub-monolayer sensitivity and relatively simple experimental setup. With combining a pump probing technique, MOKE has an ultra-fast time resolving power [3]. However, the beam spot size is limited about sub-micron due to the diffraction limit of the light, it cause the limitation of the spatial resolution. Since the interesting nanowire/nanodot size is smaller than the beam spot, it causes unwanted degradation of the MOKE signal for the nanostructure. Cowburn *et al.* [4] and Beach *et al.* [5] overcame the poor signal qualities by taking numerous numbers of averages. Furthermore when we reduce the beam spot size too small, the nanostructure will be heated, and the uncertainty of the system temperature will prevent from correct interpretation of observed data.

In this study, we propose new measurement technique which can enhance the MOKE signal from the nanowire and nanodot. The main idea is illustrated in Fig. 1. The focused laser beam consists of two parts: one is on the nanostructure and the other is on the substrate. The MOKE signal is proportional to $\Delta R / (R_{\text{sub}} + R_{\text{nano}})$, where ΔR is the difference of the reflectivity for two magnetic states and the R_{sub} (R_{nano}) is reflectivity of substrate (nanostructure) part. While there is no contribution to the ΔR from the substrate, the contribution from R_{sub} is significant in sub-micron sized nanostructure due to the large area of substrate part when the beam size of order of micron. If we reduce the reflected light from the substrate, then the MOKE signal can be enhanced. This is the key part of this study. As shown in Fig. 1, we employ an anti-reflection coated substrate instead of usual substrate. The anti-reflection condition for the single wavelength and a constant incident angle is easily found with a dielectric multilayer stack.

The calculated results are shown in Fig. 2. The MOKE signals in Fig. 2 (a) are calculated [6] for 20-nm thick Fe nanowire with various wire width for the Gaussian beam of radius of 1500 nm. Without anti-reflection coating ($R_{\text{sub}} = 30\%$), the MOKE signal is significantly dropped with wire width. However, when anti-reflection coating layer exist ($R_{\text{sub}} = 0.7\%$), the MOKE signal is slightly reduced from its bulk value. Even for the 100-nm wide nanowire, the MOKE signal is 78 % of the bulk value. Fig. 2 (b) shows the MOKE signals for various beam sizes with a 100-nm wide Fe nanowire. When the beam diameter is comparable to the wire width, the MOKE signal is almost its bulk value. Without anti-reflection coating ($R_{\text{sub}} = 30\%$), the signal decreases rapidly as the beam radius increases. However, with anti-reflection coating, ($R_{\text{sub}} = 0.7\%$) the MOKE signal is maintains 78 % of its bulk value for 1500-nm beam radius.

We found that the MOKE signal from the nanostructure can be enhanced to 78 % of its bulk values for 1500-nm radius beam with anti-reflection coating layer. This proposed method can improve the signal to noise ratio and reduce the number of averaging in the nanostructures MOKE experiments.

Selective Magnetometry using a single x-ray absorption edge.

J. Chaboy¹, M. Laguna-Marco¹, C. Piquer¹, R. Boada¹, H. Maruyama², N. Kawamura³
 1. ICMA, Zaragoza, Spain; 2. Graduate School of Science, Hiroshima University, Higashi-Hiroshima, Japan; 3. SPring-8/JASRI, Sayo, Japan

The possibility of disentangling the magnetic contribution of different atomic species within the same material has been a challenge from long time. Most of experimental techniques aimed to study the magnetic properties of materials are sensitive to the total magnetisation of the measured system and, consequently, they can not discern between the contributions of different atoms in the material.

Within this scenario X-ray Magnetic Circular Dichroism (XMCD), the difference in absorption of left- and right-circularly polarized x-rays by a magnetized sample, emerges as an outstanding tool to study magnetism by incorporating the element specificity of core level spectroscopies [1], combined with the application of magneto-optical sum rules [2,3] allowing quantitative magnetic measurements at the atomic level.

These capabilities are now incorporated as a standard tool to study the localised magnetism in many systems. However, the application of XMCD to the study of the conduction band magnetism is not so straightforward. Here, we show that the atomic selectivity is not lost when XMCD probes the delocalised states. On the contrary, it provides a direct way of disentangling the magnetic contributions to the conduction band coming from the different elements in the material.

In this work we report on an XMCD study performed as a function of the temperature at the rare-earth L_2 -edge in the case of RT_2 (R = rare-earth, T = 3d transition metal) materials. According to previous works the analysis of the R L_2 -edge XMCD spectra shows the presence of a magnetic contribution coming from the transition metal even when the rare-earth is probed. Indeed, the RT_2 compounds show a different XMCD shape for different transition metal (Al, Fe and Co). This behaviour cannot be explained

in terms of the current knowledge of the rare-earth XMCD signals at the L-absorption edges. On the contrary, the fact that the magnetic properties of the R counterpart (Al, Fe and Co) are clearly different suggests that the origin of such a behavior stems from an *unexpected* contribution arising from the T sublattice [4-6]. To account for such anomalous behaviour we have considered that the XMCD at the L_2 absorption edges is not exclusively due to the rare-earth being probed itself, but there is also a contribution from the neighbouring magnetic transition-metal atoms. In this way, the XMCD signal can be decomposed as the addition of two contributions one exclusively due to the rare-earth, $XMCD_R$, and the second due to the transition metal, $XMCD_T$. Within an atomic picture the rare-earth contribution is mainly determined by the 4f electrons and, because they are close to the free-ion values, we can assume that $XMCD_R$ contribution to the XMCD spectrum corresponds to the whole XMCD spectrum of the RAI_2 compound, as Al atoms do not carry magnetic moment, and thus $XMCD_T$ should be zero. Under these assumptions it is possible to isolate the contribution of the transition metal to the R L_2 -XMCD by subtracting from each recorded dichroic spectrum that RAI_2 with the same R. In this way, the same absorption edge yields the temperature dependence of the magnetisation of both sublattices $M_R(T)$ and $M_T(T)$. The total magnetisation built up from the values determined from the XMCD spectra shows a remarkable good agreement with the experimental values of the magnetisation measured in a commercial SQUID magnetometer at the same experimental conditions.

The reported results show the success into disentangling the magnetic contribution of different atomic species by using a single x-ray absorption edge. The addition of both individual sublattice magnetisations according to their ferrimagnetic coupling reproduces fair well the temperature dependence of the macroscopic magnetisation. Moreover, these results show that the atomic selectivity is not lost when XMCD probes the delocalised states. On the contrary, XMCD is a simultaneous fingerprint of the magnetic contributions to the conduction band coming from the different elements in the material. Taking advantage of this peculiarity we have proposed a direct method of disentangling these contributions. A consequence we have demonstrated that it is possible to perform element-specific magnetometry by using a single x-ray absorption edge.

Open-circuit one-port network analyzer ferromagnetic resonance.

C. Bilzer, T. Devolder, P. Crozat, C. Chappert

Institut d'Electronique Fondamentale, ORSAY Cedex, France

Broadband spectrometers based on transmission coplanar waveguides have recently found much success for extracting the magnetic permeability and the ferromagnetic resonance (FMR). Here, we describe a simpler instrument based on a coplanar waveguide (CPW) terminated by an open-circuit. We demonstrate a scheme to transform reflexion parameters into permeability spectra, and compare our evaluation method to measurements performed using the standardized transmission geometry.

The Network Analyser (NA) FMR technique is usually implemented using a transmission geometry, where a thin film is flipped onto the CPW [1] whose reflexion/transmission properties are monitored. The scattering matrix of the so-loaded CPW are used to extract the permeability spectra and the field dependence thereof. NAFMR set-up free of electrical artefacts are not easy to fabricate, and the measurement method is prone to errors, due to some non-repeatability of the electrical contacts during the microwave calibration of the circuitry.

In the present paper, we demonstrate a simple modification of the set-up that avoids a large part of the time-consuming and error-prone calibration procedure. Our instrument is based on a CPW terminated by an open-circuit. This geometry ensure the formation of a standing wave with no RF field near the open-circuit side of the CPW, where the sample is placed. The permeability is thus measured closer to the linear excitation regime that in transmission geometry set-ups. We analyze our configuration, and establish a scheme to deduce permeability spectra. We finally compare our method to measurements performed using the standardized transmission geometry.

The core of our set-up is a CPW, on which we load a thin film. We start by measuring the reflexion parameters $S_{11,ref}$ of the loaded CPW with a saturating field along (y). In doing so, the RF excitation field is parallel to the magnetization, such that the magnetic susceptibility χ vanishes, providing a reference measurement. We then rotate the field to align the magnetization parallel to the CPW, in order to get RF field perpendicular to magnetization, and thus to get a finite χ . We record the new reflexion parameter S_{11R} (Fig.1).

We write g_0 and g the propagation constants (wave vectors) of the CPW when respectively unloaded and loaded. We write m_r the relative effective permeability of the medium surrounding the CPW when loaded with the sample. We have $m_r = 1 + \chi c$, where $\chi \ll 1$ is a filling factor and c is the sample's magnetic susceptibility.

Some algebra and simplifications are needed to derive the relationship between the magnetic permeability and the reflexion parameter. The reflexion parameter of a loaded CPW terminated by an open-circuit at port 2 is found to be approximately $S_{11R} = \exp(-2gl)$, such that we can calculate χ an estimator of the magnetic susceptibility using:

$$\chi = \ln(S_{11R}) / \ln(S_{11Rref}) - 1$$

We have measured susceptibility spectra in both geometries: open-circuit CPW and conventional transmission CPW. The two Kittel plots obtained from the two techniques coincide almost perfectly. The relative error (Fig. 2C) is less than a percent, except at low FMR frequencies. Similarly, the linewidth determined from open-circuit measurement is very similar to the exact one.

In conclusion, we have introduced a new method to perform Network Analyser Ferromagnetic Resonance measurements. The method relies on the measurement of the microwave reflexion parameter of a coplanar waveguide terminated by an open-circuit, and loaded with a magnetic thin film. This method drastically simplifies the implementation of NAFMR, since it allows

for a more compact set-up with only one probe. It requires a calibration procedure that is considerably faster than the one needed in the usual transmission 2-port geometry. By comparing with a standardized technique [1], we have shown that the open-circuit method provides reliable measurements of the ferromagnetic resonance frequencies and linewidth.

Figure 1: Complex reflexion coefficient S_{11R} versus frequency from 50 MHz to 15 GHz for a CPW loaded with a CoFe 40nm film, submitted to a field of 40 mT along the CPW direction (black curve), or perpendicular to the CPW (red dotted curve). Inset: sketch of the set-up.

Figure 2: Comparison of the FMR resonance frequencies and linewidth obtained from the exact susceptibility determined from a 2-port analysis and the values obtained from the approximate magnetic susceptibility χ .

Discrimination of metallic coins using the scan type magnetic camera.

J. Lee¹, J. Jun²

1. Department of Information and Communication Engineering, Chosun University, Gwangju, South Korea; 2. Department of Information and Communication Engineering, Graduate School of Chosun University, Gwangju, South Korea

Fig. 1 shows the diameters and weights of coins from different countries. Coins, which have similar sizes and weights, could be used for criminal purposes because of the large differences in economic values (the exchange rates). The coins consist of paramagnetic metals or magnetically combined metals, such as gold, silver, copper, bronze, brass, aluminum, zinc, tin, nickel, platinum, iron and rhodium. Thus, skilled workers have been necessary to discriminate the coins.

In this paper, an algorithm for discriminating the coins by using a scan type magnetic camera is proposed. The device uses the linearly integrated Hall sensors array (LIHaS) [1] and the complex induced current - magnetic flux leakage method (CIC-MFL) [2]. The 64 InSb Hall sensors are linearly integrated on the Ni-Zn ferrite wafer to a spatial resolution of 0.52mm, as shown in Fig. 2 (a). Current is induced in a coin by using a small yoke type magnetizer (hereafter referred to as simply a magnetizer), which is positioned on the LIHaS, as shown in Fig. 2 (b). The pole interval of the magnetizer is 12 mm. The 255 mA alternative current with 1 kHz is run through the 1,110 turns of coil on the magnetizer.

The distribution of the magnetic field intensity [3] around each coin was measured in the 1 mm of lift-off, and processed by $\partial V_{RMS}/\partial x$, as shown in Fig. 3. The peak-distances and the integrated maximum values of $\partial V_{RMS}/\partial x$ could be used to discriminate the coins, as shown in Fig. 4. 44 cases, using 22 coins of 12 kinds from 10 countries, were examined to verify the proposed algorithm.

Apparent Image Effect in Closed-Circuit Magnetic Measurements.

A. K. Higgins¹, C. H. Chen¹, C. D. Graham², R. M. Strnat³

1. University of Dayton Magnetics Lab, Dayton, OH; 2. University of Pennsylvania, Philadelphia, PA; 3. Magnetic Instrumentation, Inc, Indianapolis, IN

Magnetic measurements made “open circuit,” typically using a VSM with the sample in the gap of an electromagnet, are subject to error from the image effect, so called because in the ideal case a magnetic image of the sample appears in the electromagnet pole pieces. The usual result is an apparent drop in the measured magnetization as the pole pieces approach saturation.

Closed-circuit measurements are not considered subject to the image effect. However, when measuring permanent magnet samples clamped between the pole pieces of an electromagnet, we observe a phenomenon like the image effect, as shown in Fig. 1. The drop in apparent magnetization can appear in quite low fields and can be large, approaching 50%. The effect depends on the length-to-diameter ratio of the sample, and is minimal for L/D greater than about 1.8. A series of experiments leads us to believe it originates in a non-uniform saturation of the electromagnet pole tips.

Samples were cylinders about 1.2 cm in diameter, with a range of L/D values from 1.8 to 0.23. They were clamped between moveable electromagnet Fe-Co pole pieces as shown in Fig. 2. Flux density B is measured with a centrally-located coil, and the field intensity H just outside the sample is measured with a pair of concentric coils of slightly different diameters, connected in series opposition. The magnetization is given by $B-H=4\pi M$ gauss. With no sample present, B is linear with H and $4\pi M$ is zero over the range of magnet gaps.

We find that:

1. The effect occurs for both hard and soft magnetic materials, with H_c from about 10 to more than 20,000 Oe and $4\pi M_s$ from about 6000 to more than 20,000 gauss.
2. The drop in apparent magnetization occurs at lower fields for materials with higher magnetic saturation.
3. Both the B and the H signals are affected.
4. The presence of a sample lowers the measured maximum field at a given magnet air gap.
5. The magnitude of the effect decreases as the value of L/D increases, and is negligible for L/D greater than 1.8.
6. The effect appears only in the first and third quadrants of the hysteresis loop.

We believe that the pole tips of the electromagnet approach saturation first in the regions immediately adjacent to the ends of the sample, as suggested by Fig. 2, because the sample magnetization increases the local flux density in the pole pieces. This happens at lower applied fields when the sample magnetization is higher. The diameter of the pole tips is much larger than that of the sample, so the magnetization of the pole tips becomes non-uniform. As the magnet current increases, the additional magnetic flux is forced to leave and enter the pole pieces primarily in an annular ring surrounding the sample cylinder. Thus the flux density outside the sample increases more than inside the sample, and the measuring coils record lower values of both B and H than they would if the flux density remained uniform. As the distance between the pole faces increases, the natural tendency of the flux density to become uniform causes the non-uniformity at the mid-plane of the sample to decrease.

Since no part of the pole pieces approaches saturation in the second quadrant (where the sample magnetization lowers the flux density in the pole pieces), second-quadrant measurements are not affected and short samples can be used. To measure high-field magnetization accurately, it is necessary to use samples with $L/D > 1.8$; even then there will be some uncertainty in the field. In addi-

tion, the radial variation of flux at the ends of the sample will be different from that at the center. It is possible that the error might be diminished by reducing the area of the pole tips relative to the cross-sectional area of the sample, or by changes in the geometry of the measuring coils.

A GMR Based System for Pulsed Eddy Current NDE of Aircraft Structures.

G. Yang, L. Udpa, S. Udpa
msu, East Lansing, MI

Abstract— Research in nondestructive evaluation of aircraft is constantly pushing the envelope in regard to the detection of increasingly smaller cracks that are embedded deep in layered aircraft structures. This paper, presents the design and development of a nondestructive inspection system that uses a pulse excitation signal to generate a field that is detected via GMR field sensors. Experimental signals are analyzed to detect the presence of cracks under fasteners.

Index Terms—Giant Magneto Resistive (GMR) sensors, eddy current, nondestructive evaluation

I. Introduction

A major challenge in the inspection of aging aircraft is the detection and characterization of cracks that occur around fastener holes in multi-layered wing structures. The large number of potential flaw sites has contributed to interest in the development of fast and reliable NDE techniques for detecting such cracks. Eddy current testing methods have served as the primary NDE modality in the aircraft industry for more than 50 years [1]. Though the technique is powerful in principle, the inspection process is often time consuming since the impedance plane signal returned by the probe is difficult to interpret and often requires special operator training. Furthermore, conventional eddy current systems are limited by the depth of penetration of fields or skin depth. This has led to the development of the pulsed eddy current testing method [2]. More recently, alternate sensors such as magneto-optic imaging (MOI) [3] sensors and giant magneto-resistive (GMR) [4] sensors have been used in conjunction with eddy current excitation to detect fields associated with the induced currents, particularly when the field levels are low and finer spatial resolution of flaws are desired.

This paper describes a system that combines the advantages of pulsed eddy current excitation with the enhanced bandwidth and sensitivity of Giant Magneto Resistive (GMR) based field sensors to maximize the probability of detecting small cracks under fasteners in airframe structures.

II. Field Measurement Approach

A schematic of the experimental system is shown in Figure 1. A current foil with a GMR sensor placed symmetrically is excited by a 50 Hz square wave. When the probe is at a defect free location, the field at the GMR sensor is largely tangential to the test object and the signal measured is close to zero. When the symmetry of the induced current is disturbed by rivets and cracks, a transient signal can be measured by the GMR sensor. The GMR signal contains information relating to discontinuities in the sample. As the rivet and subsurface defect are located in different layers of the sample, the temporal evolution of the measured signal is indicative of the state of the different layers of the specimen. Consequently, the rivet and subsurface defect can be efficiently detected and separated by analyzing the temporal evolution the GMR sensor signal.

III. Results

The test sample consists of two layers of aluminum with a rivet and a subsurface radial crack as shown in Figure 2. When the probe scans the surface of the sample, the transient time signal from the GMR sensor is sampled and stored for each sensor position.

The response from the GMR sensor is shown in Figure 3. The curve labeled 1 is the low amplitude signal due to a symmetric geometry, the curve labeled 2 is caused by the asymmetry due to the rivet alone, whereas the curve labeled 3 is due to the asymmetry caused by the rivet and crack under the fastener head.

IV. Conclusions

A new inspection system that uses pulsed eddy current excitation applied to a planar coil and employing a GMR sensor for measuring fields associated with induced currents has been proposed. Initial results obtained show the system is capable of detecting small cracks buried under the fastener head in a multilayer geometry.

Fabrication and analysis of high-performance integrated solenoid inductor with magnetic core.

D. Lee¹, K. Hwang², S. X. Wang¹

1. Materials Science and Engineering, Stanford University, Stanford, CA; 2. Intel Corporation, Folsom, CA

Introduction:

Use of magnetic core with high permeability in the integrated inductor was proposed decades ago to significantly increase the inductance by the relative permeability of the magnetic material used [1]. However, the reported inductance enhancements over air core so far have been very limited. Here we present the high performance integrated inductors with a single layer of magnetic core, low coil resistance and small area consumption. The inductor devices show inductance enhancements as high as 34 times over the air core and large inductance densities, and their properties can be accurately described by the analytical models we used in the design process.

Experiments:

Based on the established analytical models for discrete inductors, the careful analyses of our previous experimental results [2], and the comparison with the results of finite element electromagnetic field simulation tools, we were able to put forward a set of analytical models to describe the device properties of integrated solenoid inductors. Design parameters were optimized using these models to achieve a high inductance while maintaining the lateral device area $< 1 \text{ mm}^2$ and the coil resistance $< 1 \text{ } \Omega$.

The integrated inductors were fabricated on Si wafers. $5 \text{ } \mu\text{m}$ thick copper was used as the conductor layer, and $2 \text{ } \mu\text{m}$ thick CoTaZr alloy with the relative permeability of ~ 600 [3] was chosen as the magnetic core layer. Polyimide was used as the interlayer insulating material. Fig. 1 shows an integrated magnetic inductor having the number of coil turns $N = 17.5$ with the probe pads and ground ring.

The frequency-dependent device properties of the inductors were measured using a network analyzer.

Results and Discussion:

The inductance increased with the number of turns and reached a value of 70.2 nH at 10 MHz with $N = 17.5$ (Fig. 2(a)). This is an enhancement by a factor of 34 from 2.0 nH of the air core inductor with the identical geometry, which is higher than the recently reported record-high inductance enhancement by 19 [4]. The device area for $N = 17.5$ is 0.88 mm^2 , corresponding to an inductance density of 80 nH/mm^2 , with DC resistance of $0.67 \text{ } \Omega$. This is significantly more than the reported $20\sim 40 \text{ nH/mm}^2$ for coil resistances less than $1 \text{ } \Omega$ [5]. By shrinking the lateral dimensions while maintaining the vertical dimensions unchanged, the inductance density further increased to 219 nH/mm^2 without affecting the coil resistance significantly.

The measured inductance values and the calculations using the analytical models were compared in Fig. 2(a). The demagnetization effect in the finite-sized magnetic core was mainly considered in estimating the magnetic contribution to the inductance. The good agreements confirm that the analytic models can accurately describe the inductances of air core and magnetic inductors. The expected inductance enhancement was about $37\times$ for $N = 17.5$, which is very close to the observed enhancement of $34\times$.

The use of magnetic core comes with the cost of introducing magnetic power losses at high frequencies. The resistance for the magnetic inductor increases significantly with the frequency, and this is greater for higher number of turns N . A higher N generates a larger inductance gain, and this

in turn results in a higher magnetic core contribution to the resistance at high frequencies according to the fundamental trade-off described by the analytical models. Resistance and quality factor were calculated and compared with the measurement data for $N = 17.5$ as shown in Fig. 2(b). The excellent agreements between the calculation and measurement results confirm the validity of the proposed analytical models. The quality factor was above 6 at $20\sim 30 \text{ MHz}$ for $N = 17.5$.

In summary, we have designed and fabricated high performance magnetic inductor devices suitable for integration to a semiconductor chip. The device properties of the integrated magnetic inductors are well understood with improved analytical models and can be further optimized for various applications and frequency ranges of interest.

Thin Film Integrated Power Inductor on Si and Its Performance in a 8MHz Buck Converter.

N. Wang, T. O'Donnell, R. Meere, F. Rhen, S. Roy, C. O'Mathuna
Microsystems Centre, Tyndall National Institute, Cork, Ireland

It is an ever increasing demand to miniaturize the voltage regulators in the portable electronic devices. Although there has been considerable recent progress in the integration of the active parts of such converters, significant miniaturization of the overall converter is retarded by the need to miniaturize and integrate the passive components[1-11]. Recently, some DC/DC converters with inductors integrated into the converter package have been introduced[12-13]. The technology developed by authors is to seek a different approach by integrating inductors on to silicon using cost-effective and standard IC fabrication compatible techniques. This provides monolithic power-supply-on-chip (PSOC) solutions with an adequate performance for low power consumption applications in the portable electronic devices, such as PDAs, mobile phones[14].

The fabricated inductor consists of a single layer of race track shaped copper winding (7 turns) sandwiched between two layers of magnetic material (NiFe alloy) deposited by electroplating. Its inductance is approximately 0.45 μ H. The frequency response test shows that the inductance can hold up to at least 20 MHz. The maximum Q factor is about 12 at 5 MHz, which is the highest reported Q factor of a micro-fabricated inductor realized using standard electrochemical deposition technique. The bias current characteristic test shows the inductance only drops by approximately 10% with a 500mA DC current, which implies that it is capable of handling at least 500mA current without saturation.

MIC2285YML is a commercially available buck converter with a fixed switching frequency of 8MHz from Micrel[15]. It requires a 0.5 μ H external inductor. An inductor from Murata with an inductance of 0.47 μ H was originally mounted on the test board. The micro-fabricated thin film inductor was used to replace the chip inductor. A picture of the converter evaluation board with micro-inductor wire bonded on top is shown in fig. 1. The measured efficiencies of the buck converter using the on silicon integrated thin film inductor with various load currents are shown in Figure 2. The efficiencies of the converter using the original chip inductor are also shown in the graph for comparison. The full specifications of the tested inductors and the break down of the losses in both tested inductors will be detailed in the full paper.

When using the thin film inductor, the converter efficiency is still over 80% for the load current between 0.1 A and 0.25A. The difference in converter maximum efficiency between using the commercially available thinnest chip inductor and Tyndall integrated inductor is approximately 3%. The work demonstrated the feasibility of implementing thin film integrated inductors in a DC/DC converter. Although the thin film inductor has a relatively larger footprint area ($2 \times 5.75 \text{ mm}^2$) compared to that of the tested Murata chip inductor ($2 \times 1.25 \text{ mm}^2$), the thickness of the effective part of the device is less than 0.15mm whereas the chip inductor is 0.55mm thick. This can be a great advantage when a very small thickness is required in particular applications. Moreover, the IC fabrication compatible process developed by authors enables to fabricate inductors onto the same substrate of the power management IC to realize a truly monolithic DC/DC converter without requirement of using external inductors.

CoNiFe applied in Microinductors for integrated dc-dc converters.

*T. El mastouli, J. Laur, J. Sanchez, M. Brunet, D. Bourrier, M. Dilhan
ISGE, Laboratory for Analysis and Architectures of Systems (LAAS - CNRS), Toulouse Cedex 4,
France*

1. Introduction:

As it is necessary to reduce size and weight of electronic devices for portable micro-systems, manufacturing of magnetic components dedicated to power conversion becomes essential. This miniaturization requires developing new techniques and materials that increase the efficiency of micro-inductors associated in integrated DC-DC converters. This paper deals firstly with the optimisation of the electrodeposition of CoNiFe and with the integration on silicon of “spiral-type” inductor topology. Electroplating techniques are used to achieve the copper conductor and the CoNiFe laminated magnetic core and several investigations on the electroplating bath's parameters have been realized in order to obtain the adequate magnetic properties. Finally, a $1\mu\text{H}$ micro-inductor prototype has been fabricated and characterized.

The proposed structure consists in a copper spiral sandwiched between two laminated magnetic layers. The laminated magnetic core would reduce the effects induced by the influence of eddy currents and skin effect due to the high frequency switching operation. As the energy density in micro-inductors is limited by the saturation flux density B_{sat} of magnetic core, B_{sat} has to be high. In our case, the material for the magnetic core selected is CoNiFe which presents a very high B_{sat} ($>2\text{T}$), low coercive field H_c ($<8\text{Oe}$) [1] and a thin film magnetic permeability μ of about 1000. This magnetic material has been selected to replace the NiFe (80%-20%) classically used for this kind of the integrated devices. The NiFe have a low $B_{\text{sat}} = 1\text{T}$ [1]. The main feature of CoNiFe is the resistivity of about $30\mu\Omega\cdot\text{cm}$ which is considerably better than the NiFe which has a resistivity about $20\mu\Omega\cdot\text{cm}$.

2. Optimization and characterization of electrodeposited CoNiFe:

Studies made on CoNiFe have shown that the best ratio of CoNiFe is about 60%-15%-25% [1], and to achieve this ratio several bath formulations have been investigated. We have chosed to work on the bath presented in [2], our work aimed to optimize an electroplating process enables the electrodeposition of thick $\text{Co}60\%\text{Ni}15\%\text{Fe}25\%$ with good adhesion to substrate and with optimal magnetic properties. To achieve our goal, several parameters have been investigated by changing temperature, pH, current density of plating process and concentrations of additives (saccharin and Sodium Lauryl sulphate or thiourea). The details of the optimisation process will be given in the final paper. The optimal deposit conditions selected are: Bath temperature of 40°C , current density of $3\text{A}/\text{dm}^2$ and pH of 1.5. These conditions were used for the realized inductor's magnetic core. The composition of the magnetic layer determined by quantitative energy dispersive X-ray analysis. The measurement shows a CoNiFe layer of the following stoichiometry (60%-15%-25%).

The magnetic characteristics of CoNiFe electrodeposited layers extracted from the Hysterisis loop are: B_{sat} of 2.2T , H_c of 10Oe and relative permeability (μ_r) of 250. These characteristics are measured by SQUID and Vibrating Sample Magnetometer. The coercive field (H_c) can be reduced by applying a magnetic field during plating to induce a hard axis (and easy axis) in the direction of the magnetic flux in the structure. The resistivity is measured by the four point probes method. The measured resistivity value is $30\mu\Omega\cdot\text{cm}$.

3. Microfabrication and electrical characterization of microinductors prototype:

With development of the CoNiFe electrodeposition and using the process sequence of the micro-inductor fabrication, we have been successfully realized devices of the “spiral type” structure. Fig-

ure 1 represents the cross section of a “spiral type” prototype showing the copper spiral located between CoNiFe laminated magnetic core.

The measurements of the inductance and the series resistance of the realized prototype as a function of frequency were done using impedance analyzer (Agilent 4294A 0-110MHz). For frequency less than 1MHz , the fabricated prototype shows nearly constant inductance value and dc series resistance of about respectively $1\mu\text{H}$ and 1.2Ω . However, for the frequencies superior to 1MHz , on one hand, the inductance value slightly decreases with increasing frequency. On the other hand, the resistance increases due to losses that are mainly in the magnetic core, since the lamination is beneficial for frequencies up to 500kHz . For greater frequency, eddy currents are generated in the magnetic core.

These micro-inductors are used in dc-dc converters. These measurements have been carried out at 2 and 3MHz . That confirmed the presence of previously mentioned resistive effect.

Electric power consumption by CPU in desktop, laptop and smart phone are 70 ~ 100 W, 10 ~ 30 W and 1 ~ 2 W, respectively. At present, about 1 V is supplied to CPUs; therefore, current is increased up to 100 A in desktops. However, a high current acceptable on-chip dc-dc converter has not yet been developed.

In this paper, we present a ferrite planar inductor with Q over 50 for 10 ~ 100 MHz for a 1 ~ 2 W buck type dc-dc converter module with 0.25 V and 5 A output. HFSS simulations were performed on three different inductor structures to evaluate inductance. These structures are shown in Fig. 2(a); namely UA-SS, UA-DS, and UA-C. We have also compared performance of NiZnCu ferrite inductor (UA-C) to CoNbZr magnetic inductor (UA-C).

A spiral structure is used because of its high L/mm² property. Copper coil with area of 5 mm x 5 mm was designed on 600 μ m thick Si. Cu coil thicknesses are 50 μ m and 15 μ m at 10 MHz and 100 MHz, respectively. These thicknesses are greater than the skin depth at a given frequency. Accordingly, cross sectional coil area was designed over 25,000 μ m² to withstand joule heating by maximum 5 A rated current [2,3]. Therefore, coil width is fixed at 500 μ m. We used two different magnetic materials for UA-C inductor, which are CoNbZr with μ (permeability) = 1000 up to fr = 0.7 GHz and NiZnCu ferrite with μ = 40 at 50 MHz and 20 at 100 MHz, for comparison of inductor performance. In principal, inductor needs inductance of 125 ~ 30 nH at 10 ~ 100 MHz [4]. Values of L, Q, R and C are calculated from simulated S parameters [5], which are generated by Ansoft HFSS simulation.

Figure 2(b) shows frequency dependence of inductance for three types of inductor. It is found that the highest inductance of 1.372 μ H at 10 MHz was obtained from the type UA-C inductor. This inductance is 790% higher than air-core inductor. It is attributed to reduction of leakage magnetic flux due to closed magnetic edges. Therefore, we choose the UA-C structure to compare quality factor for two different magnetic materials; CoNbZr and NiZnCu ferrite.

From our simulation results, inductor performance is given in Table I. The NiZnCu ferrite film UA-C inductor has smaller parasitic C, large insulation property represented by R1 (resistance between copper coil and substrate) and R2 (resistance between coils), and a high Q value as compared to both air-core and CoNbZr UA-C inductors. Quality factor Q for NiZnCu UA-C and CoNbZr UA-C inductors are 97.5 and 1.3 at 100 MHz, respectively.

In addition, the effects of top ferrite film thickness and tan δ on the Q factor were investigated for UA-C inductor which has 2.5 turns and 3 μ m thick bottom ferrite. The results are presented in Fig.3 The quality factor Q increases with increasing the top ferrite thickness and also with permeability. On the other hand, the quality factor Q decreases with increasing loss tan δ and is higher for smaller permeability.

In conclusion, the following design and material properties are required to achieve Q of 50 of inductor at 10 MHz for 0.25 V and 5 A dc-dc converter module: inductor structure – UA-C, thickness of top NiCuZn ferrite > 100 μ m, permeability of ferrite > 20, copper thickness > 2 x Skin depth, and loss tan δ < 0.02.

Synthesis of Bi-Zn-Al-B-Si-O nano-glass by sol-gel method for multilayer chip inductors.

S. An, S. Wi

EMC R&D Group, Samsung Electro-Mechanics, Gyeonggi-Do, South Korea

Introduction

Recently, with the rapid development of mobile communication and miniaturization of electronic devices, low-cost are greatly demanded. NiZnCu ferrites are extensively used in the fabrication of multilayer chip inductors (MLCI) because of their relatively low sintering temperatures, high permeability in the high frequency region, high electrical resistivity, mechanical hardness, and chemical stability [1-2]. To fabricate MLCIs, ferrite layers and internal conductors are alternately laminated and then co-fired to form the monolithic structure. In MLCIs, Ag (melting point=961 °C) is used as the internal electrode material due to its low resistivity and lower cost. For successful fabrication of MLCI, the sintering temperature of NiZnCu ferrite should be reduced to 900 °C to realize the co-firing of the ferrite and Ag electrode materials. For this purpose, suitable amount of low melting-point sintering aids such as Bi_2O_3 , MoO_3 , V_2O_5 and glass are usually introduced into NiZnCu ferrites [3]. In this work, Bi-Zn-Al-B-Si-O nano-glass was used as a sintering aid for the densification of the NiZnCu ferrites and the initial permeability, quality factor, density and saturation magnetization were also measured.

Experiments

$\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$, $\text{Al}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$, $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, $\text{C}_3\text{H}_9\text{BO}_3$ and $\text{Si}(\text{OC}_2\text{H}_5)_4$ were dissolved in 2-methoxyethanol and acetic acid. The solution was refluxed at 60 °C for 24 h and dried at 120 °C for 48 h in oven. The obtained powder was annealed at 300 °C for 2 h in air and finely nano-glass powdered. NiZnCu ferrites powders were mixed with an appropriate amount of 0.1-2.0 wt% Bi-Zn-Al-B-Si-O nano-glass powders. The granulated powder with an amount of 0.5 wt% polyvinyl alcohol as a binder was pressed at a pressure of 2000 kgcm^{-1} to form green toroidal specimens. The specimens were kept at 600 °C for 1 h in order to decompose and vaporize the organic components and then sintered at 840-900 °C for 2 h in air. Initial permeability and quality factor of sintered toroidal specimens were measured using a HP4286 impedance analyzer. The saturation magnetization and coercivities of the powders were measured with a vibrating sample magnetometer at a maximum applied field of 5 kOe at room temperature.

Results and discussion

Bi-Zn-Al-B-Si-O nano-glass was prepared by sol-gel method. The x-ray diffraction patterns of the compounds showed a non-crystalline phase in the nano-glass materials. Figure 1 shows the SEM images of nano-glass annealed at 300 °C. According to SEM images, the particle size was estimated to 60.3 nm with narrow size distribution. Using sol-gel method, nano-sized glass materials can be obtained, which have larger surface area and larger surface free energy than micron-sized glass materials prepared by the conventional melt-quenching method. As shown in Fig. 2, permeability increases with the increase in the nano-glass content in NiZnCu ferrite. The increase in initial permeability with nano-glass content may be primarily attributed to the increase in bulk density. It is known that ferrites with higher density and larger average grain size possess a higher initial permeability [4]. The initial permeability of 0.1 wt% nano-glass added sample was about 62.6. It should a sharp increase from 0.4 wt% to 0.5 wt% nano-glass addition, and then reached the maximum value (211.2) at 1.0 wt% addition level. Beyond 1.0 wt% addition level the initial permeability decrease again with further increase in the nano-glass content. The quality factor and saturation magnetization of 0.5 wt% nano-glass added sample for NiZnCu ferrites sintered at 880 °C

was about 143 and 386 emu/cc, respectively. As a result, Bi-Zn-Al-B-Si-O nano-glass systems were found to be useful as sintering aids for MLCIs.

Electrically Tunable Thin Film Magnetic Core using Synthetic Antiferromagnet Structure.

N. An, A. Jander, P. Dhagat

Electrical Engineering&Computer Science, Oregon State University, Corvallis, OR

We demonstrate an electrically tunable thin film magnetic core using a synthetic antiferromagnet (SAF) structure. It consists of two ferromagnetic layers antiferromagnetically coupled together through an exchange coupling layer. Variation of susceptibility is achieved by leading a current through the SAF structure. The experimental data show that with 2mA internal current, a tuning range (relative change in susceptibility) of 10% can be achieved at 800Hz. Substantial further improvements in tuning range is expected by optimizing the structural designs and exchange coupling strength.

Fig. 1 shows the SAF test structure. It contains three parts: Part (1) and (3) are two Al strips, they serve as electrical contacts for the internal current; Part (2) are 600 parallel SAF lines, each of which is comprised of two 12-nm-thick NiFe layers coupled through a 0.7-nm-thick Ru layer (Fig. 2). This structure, covering an area of approximately 1cm², provides enough magnetic material for “bulk” susceptibility measurements. The width and the spacing of the SAF lines are 10 μ m and 5 μ m respectively.

Fig.3 illustrates the experiment setup. The Helmholtz coils are used to produce a uniform ac field. About 6 Oe, 800 Hz magnetic field is applied parallel to the SAF lines. The current source is used to apply current pulses to the SAF test structure. The purpose of using current pulse instead of dc current is to eliminate thermal effects. The signal induced in the pick-up coils by the SAF test structure is detected using a lock-in amplifier. The change in induced voltage as a function of current pulse amplitude is measured with the oscilloscope.

Fig. 4 shows the susceptibility change as a function of internal current. $\Delta\chi/\chi$ represents the relative change in susceptibility, which is proportional to the induced voltage. As predicted in our previous analysis (1), the susceptibility increases with current. This is because the magnetic field generated by the internal current rotates the magnetizations of the two NiFe layers, which results in a net magnetization change along the applied field.

In conclusion, the susceptibility of thin film magnetic core can be adjusted by an internal current. The experiment results are consistent with the model developed in our previous work. By incorporating the SAF structures into the cores, electrically tunable, on-chip inductors can be realized.

The effect of magnetic coating layer thickness on the performance of tunable magnetic inductors.

N. Ning¹, X. Li¹, H. Seet¹, W. Ng¹, Y. Xu²

1. Mechanical Engineering, National University of Singapore, Singapore, Singapore; 2.

Electrical and Computer Engineering, National University of Singapore, Singapore, Singapore

A tunable magnetic inductor has been reported recently [1]. The tuning effect of such tunable magnetic inductor is achieved by modulating the permeability of the soft magnetic layer in a magnetic inductor body of either sandwiched thin film structure or composite wire structure, via applying a bias magnetic field generated by the insulated coil wound on the magnetic inductor body. In a further understanding of the performance of the tunable magnetic inductor of composite wire structure, the tunability of inductance in relation to one of the key parameters in such tunable inductor - the magnetic coating layer thickness, is presented in this paper.

Samples of the magnetic inductor body of composite wire structure were produced by electroplating a layer of $\text{Ni}_{80}\text{Fe}_{20}$ with varying thickness t_m of 2.3 - 6.2 μm , onto a Cu wire of 20 μm in diameter and 2 cm in length. The resultant inductance L , resistance R , and quality factor Q of the inductor samples, under the application of a DC bias magnetic field H_{ex} varying from 0 to 43 Oe along the length of the wires, were measured at room temperature using a precision impedance analyzer (HP4294A). The rms value of the AC current through the inductor was kept constant at 10 mA, and the frequency f of the current was varied from 100 kHz to 110 MHz. To represent the tunability of the inductance, the relative variation of inductance was defined as $\Delta L/L_0 = (L - L_0)/L_0$, where L_0 is the inductance of the tunable magnetic inductor without a bias magnetic field.

Fig. 1 (a) and (b) show relative variation of inductance $\Delta L/L_0$ versus the bias magnetic field H_{ex} for the studied inductors of different t_m ranging from 2.3 μm to 6.2 μm , at a low frequency of 100 kHz and at a high frequency of 100 MHz, respectively. As can be seen in Fig. 1 (a), the curves for $t_m = 2.3 \mu\text{m}$ and $t_m = 3.6 \mu\text{m}$ are similar, which can be described as a pattern that the larger the values of t_m , the larger the values of $\Delta L/L_0$, whereas the curves for $t_m = 4.4 \mu\text{m}$ and $t_m = 6.2 \mu\text{m}$ are similar in a different pattern, in which the larger the values of t_m , the smaller the values of $\Delta L/L_0$. Interestingly, as can be observed in Fig. 1 (b), all the curves appear to follow a same pattern, in which the larger the values of t_m , the smaller the values of $\Delta L/L_0$.

These pattern differences as observed in Fig. 1 (a) and (b), are possibly because the increase of the coating thickness tilts the direction of the easy axis towards the wire axis, as the samples were electroplated with constant plating current. Given that the easy axis makes an angle θ_k with the circumferential direction, the field dependence of the transverse susceptibility can be calculated [2], provided that the simple model of a uniaxial single domain is used, as shown in Fig. 1 (c).

As t_m increases, θ_k increases. When θ_k increases to certain level, e.g. 60° , the dominating magnetization process in the coating layer is changed from domain displacement to moment rotation.

At the frequency of 100 kHz, for the magnetic inductor of $t_m = 2.3$ and $3.6 \mu\text{m}$, the domain wall movements in the coating layer were nearly damped, and the moment rotations thus dominated the magnetization process. Therefore, the circumferential permeability μ_t , and thus $\Delta L/L_0$, increased with increasing bias field until reaching the anisotropy field (about 1.7 Oe in this case). After the maximum value of μ_t was reached, μ_t , so did $\Delta L/L_0$, decreased with increasing H_{ex} , until the magnetization was saturated. When the coating thickness t_m increased to a certain level, e.g. $4.4 \mu\text{m}$, the domain displacement dominated the magnetization process. The total circumferential permeability monotonically decreased with respect to the bias field.

At the frequency of 100 MHz, for the inductor of all thicknesses discussed, the moment rotations dominate the magnetization process. μ_t and $\Delta L/L_0$ decreased with increasing t_m and θ_k .

The results indicate that there is a critical thickness for the coating layer, below which the tunability of L under a weak bias magnetic field is high (up to 50.6% at 100 kHz and 5.3% at 100 MHz, when H_{ex} is 1.7 Oe) and is proportional to the coating layer thickness t_m , and above which the tunability of L under a weak bias field is low (up to 6.6% at 100 kHz and 2.5% at 100 MHz, when H_{ex} is 1.7 Oe) and is inversely proportional to t_m . To the tunability of L of such tunable magnetic inductors, the increase of t_m has an equivalent effect as decreasing the operating frequency f . The thickness and the operating frequency f together determine that the dominating magnetization process in the coating layer is the domain displacement or moment rotation, which consequently determines the response of inductance, resistance, and quality factor of the tunable magnetic inductor.

Audible noise from amorphous metal and silicon steel based transformer core.

D. Azuma, R. Hasegawa
Metglas, Inc., Conway, SC

1. Introduction

The most important property of a transformer core is core loss or no-load loss in light of its energy efficiency. At this point Fe-based amorphous metals are superior to the conventional silicon steel as a core material. As another aspect, audible noise from transformer becomes an additional important factor, since electric power distribution systems are close to the residential area with increasing population density due to the recent industrial growth. It has been recognized that a transformer based on Fe-based amorphous metals is noisier than that based on silicon steels. The noise of a transformer consists of the following two parts: (1) No-load noise caused by magnetization of a core. It is generally assumed that no-load noise arises from magnetostriction; (2) load noise caused by electromagnetic force in conducting windings. Though there are several standards for measurement methods of transformer noise, these methods are not for transformer cores [1]-[3]. It, however, is important to measure audible noise of a core, because the source of no-load noise is from a magnetized core and when a direct comparison among noises from cores with different materials is needed. In this article we report on the measurement results of audible noise generated from magnetized model cores based on Metglas® 2605SA1 and newly developed 2605HB1 alloys [4], and M3 silicon steel for distribution transformers in hemi-anechoic chamber accordance with ISO 3744 Standard [5].

2. Experimental

Configurational same model cores based on SA1, HB1 alloys and M3 silicon steel were prepared weighing about 73 kg for SA1 core, 75 kg for HB1 and 89 kg for M3 material. The annealing temperatures for amorphous cores were 320°C - 350°C for and 300°C - 330°C for SA1 and HB1 alloy, respectively. A DC magnetic field of 2000A/m was applied along cores' circumference direction during heat treatment to induce magnetic anisotropy in the amorphous metal-based cores. Audible noise measurement on excited cores was conducted in a hemi-anechoic chamber (4.0 m x 3.7 m x 3.0 m) qualified in accordance with ISO 3744 Standard. Sound power levels were determined by sound pressure levels from 100 Hz to 25 kHz measured by ten fixed microphones located on a 1.4 m radius hemispherical measurement surface.

3. Results and Discussion

Fig.1 depicts exciting power as a function of induction for amorphous metal-based cores and for an M3-based core. Exciting power is lower than that of M3 for induction level below 1.4 T and 1.5 T for amorphous SA1 and HB1 core, respectively. Fig. 2 illustrates A-weighted sound power level [5] for cores shown in Fig. 1 as a function of operating induction. M3 core shows the lowest sound power level above induction level of 1.3 T. It is noted that in the core based on HB1 material the operating flux density can be increased by about 0.05 T with the same noise level as that of SA1. Since operating flux density of M3-based transformer is usually 1.6 T at 60 Hz, its sound power level is 56 dB according to Fig.2. The same level of noise is generated from SA1 and HB1 cores at the typical operating induction of each material (SA1: 1.35 T, HB1: 1.4 T). Above results do not necessarily reflect the audible noise of a finished transformer, since the measurement was conducted on the same core configuration and the actual core design for the same rating transformer depends on material grade, transformer specification etc. However it has been reported that optimally designed 25 kVA transformers had noise levels at 33 dB and 40 dB for amorphous metal and

silicon steel based units, respectively [6]. The amorphous metal use in these units was an Fe based SA1-like alloy. When we use HB1 alloy, a noise level lower than 33 dB would be expected.

Development of a Novel Three-Phase Laminated Core Variable Inductor.

K. Nakamura¹, S. Hisada¹, K. Arimatsu², T. Ohinata², K. Sakamoto², O. Ichinokura¹
 1. Graduate School of Engineering, Tohoku University, Sendai, Japan; 2. Tohoku Electric Power Co., Inc., Sendai, Japan

Introduction

Importance of stabilizing line voltage in electric power systems is increasing every year, as a result of increasing nonlinear loads and introducing renewable and distributed energy resources such as fuel cells, wind-turbine, and photovoltaic power. One effective solution of this problem is reactive power compensation.

A variable inductor, which can be used as a reactive power compensator [1], consists of only magnetic core and coils, but can control its winding inductance by using magnetic saturation. Hence, it can generate from leading to lagging reactive power continuously by combining with a fixed capacitor. The variable inductor has a simple and robust structure, high reliability, and low cost. These features are suited for applications in electric power systems.

This paper presents a novel three-phase laminated core variable inductor to reduce size and weight as compared with a conventional single-phase variable inductor. First, characteristics of the proposed variable inductor are calculated by reluctance network analysis (RNA) and finite element analysis (FEA). Next, a trial 4 kVA variable inductor is demonstrated.

Characteristics of a three-phase laminated core variable inductor

Fig. 1 illustrates a schematic diagram of the proposed three-phase laminated core variable inductor. Primary windings N_1 turn around the six yokes and connected to dc control voltage V_{DC} . Contrary to this, secondary windings N_u , N_v , N_w turn around the six legs respectively and connected to a three-phase ac power source. In the figure, the arrows indicate primary and secondary flux flows. Effective inductance of the secondary winding can be controlled by primary dc excitation since the both fluxes share magnetic paths in the yokes. Fig. 2 shows the specifications of the proposed variable inductor.

RNA is employed to estimate performance of the proposed variable inductor [2]. At the beginning, the core is divided into multiple elements as shown in Fig. 3(a). Surrounding space is also divided to consider flux leakage. Every divided element is expressed in a three-dimensional magnetic circuit as shown in Fig. 3(b). In the core region, these reluctances are determined by a $B-H$ curve of core material and dimensions of the element. On the other hand, in the space region, reluctances are given by a vacuum permeability and the dimensions.

Fig. 4(a) shows the reactive power characteristics of the variable inductor calculated by RNA and FEA, and (b) indicates the calculated total distortion factor of the secondary currents i_u , i_v , i_w . From the figures, it is understood that the proposed variable inductor can control the reactive power linearly and continuously, and that the secondary current is almost sinusoidal.

Demonstration of a trial 4 kVA variable inductor

Based on the above results, we tried to make a 4 kVA three-phase laminated core variable inductor. The specifications of the trial variable inductor are the same as Fig. 2. Fig. 5 shows a photo of the trial variable inductor. Fig. 6(a) shows the measured reactive power characteristics, and (b) indicates the total distortion factor of the secondary current. These figures indicate that the proposed variable inductor has good controllability and sinusoidal output current as in the case of the calculation.

Conclusion

The novel three-phase laminated core variable inductor has been proposed. This paper has indicated that the proposed variable inductor can control the reactive power linearly and the harmonics are remarkably low.

Magneto-mechanical resonance in a 3-phase transformer core under PWM voltage excitation.

X. Yao¹, P. P. Thant², A. J. Moses¹, F. Anayi¹

1. School of Engineering, Cardiff University, Wolfson Centre for Magnetics, Cardiff, United Kingdom; 2. Drilling & Measurements, Schlumberger, Aberdeen, United Kingdom

The causes and reduction of transformer noise has been the subject for many articles even before discovering that magnetostriction was the main source of noise in transformer cores. However, only sinusoidal excitation was considered in most of these studies.

Transformers subjected to PWM excitation are becoming more common in industrial applications such as active power line conditioner and renewable energy supply systems[1].

Therefore, improvement in the performance of cores under PWM excitation has become prominent. Very limited research has been reported on acoustic noise for transformer core under PWM excitation[2] with almost no study has been reported on magneto-mechanical resonance in cores. If a transformer core is subjected to resonance under magnetisation, the vibration of the core can enhance the output acoustic noise of the core as well as flapping of laminations which could lead to damage of the surface insulation coating.

In this investigation, acoustic noise and vibration behavior of a model 3-phase transformer core under PWM excitation at no-load condition with increasing switching frequency were analysed.

The core was assembled using laminations each of 0.27 mm thick grain-oriented 3%-Si electrical steel which Thant and Moses suggested that it would resonate when magnetised at approximately 1.5 kHz in the form of Epstein strips[3]. The core dimensions and positions at which acoustic noise and vibration were measured are shown in fig.1.

A 3-phase PWM inverter was used to supply the three primary windings with delta-connection and enabled the core to be magnetised up to 1.5 T. Sound pressure was recorded using a microphone[2], which was placed 0.5 m vertically above the core and moved among point 1, 2, 3 and point 5 in turn; vertical vibration of the core surface at points 1,2,3 and horizontal displacement on the side of the core at point 4 were measured using single-point laser vibrometer(SPLV)[3], vibration signal from SPLV were recorded by a digital oscilloscope.

Throughout the experimental work, modulation index m_a was in the range of 0.5 to 1.2. Switching frequency f_s was varied from 1 to 3 kHz while the magnetisation frequency f was set at 50 and 100 Hz.

Results of resultant acoustic noise and average peak-to-peak horizontal displacement at point 4 are shown in Table 1.

Fig.2(a-c) show the harmonic components of horizontal displacement at point 4 under PWM excitation at modulation index $m_a=0.6$, $f=50$ Hz, $B_{peak}=1.5$ T, $f_s=1, 2$ and 3 kHz respectively. The results obtained under PWM excitation were compared with measurements made under sinusoidal excitation at corresponding condition.

The displacement at fundamental frequency decreased with f_s increasing and increased harmonic components of 3-4 kHz was observed. However, at $f_s=3$ kHz (fig.2 c), the amplitude of harmonic component at 3 kHz is higher than at $f_s=1$ kHz and 2 kHz, indicating a magneto-mechanical resonance behavior.

The resultant acoustic noise measured under PWM excitation is around 11-13 dB greater than under corresponding sinusoidal excitation due to higher harmonics in the core vibration. The average result of horizontal displacement is decreased around 0.05 μm with increasing f_s from 1 kHz

to 3 kHz is due to the lower amplitude of harmonic content of the displacement. Similar trends in vertical vibration were found above other points on the core surface with increasing f_s . Results shows that acoustic noise and displacement decrease with increasing f_s for the 3-phase core under PWM excitation. However, near the resonance frequency (when $f_s=3$ kHz), amplitude of harmonic component at 3 kHz increases. The observed magneto-mechanical resonance phenomenon could be regarded as a possible cause of deterioration of transformer cores performance by increasing vibration and acoustic noise.

Abstract

A model of the coupling impedance between two non-coaxial single turn circular placed into two parallel planes that are located inside a multilayer media is derived. The model has been tested and validated by means of measurements.

Introduction

Domestic induction cookers consists of an electronic power stage [1], that supplies medium-frequency current, between 20 to 100 kHz, to a resonant tank that consists of an inductor and a series connected resonant capacitor. The inductor system, that is composed by a coil and the multilayer media, can be electrically modelled by its frequency dependent impedance $Z(\omega)$ that consists of a serial RL circuit [2] [3] that can be evaluated from analytical expressions, as shown in Fig. 1, where the expressions of $A_{ko}(\beta)$ and $B_{ko}(\beta)$ are functions of the positions and the physical properties of the layers. Usually, a domestic induction cooker has got more than one cooking zone, but each of them is made up one inductor and it works independent to another. However, recent developments include cooking areas composed by several coupled inductors, thus, it is necessary to model the coupling among them. We define the impedance matrix $Z(\omega)$ for a n-coil system, where each element Z_{ij} is the ratio of the voltage induced in the coil i by the electric field of the inductor j, divided by the current that inductor j drives.

Analytical Model

The coupling impedance expressions between two filiform single turn inductor placed inside a multilayer media is carried out by integrating the electric field along the turn i. This expression is performed in the same way as shown [4] in a single parameter integral and its final expression appears in Fig. 2. The multilayer contribution is included in the expressions of coefficients $A_{ko}(\beta)$ and $B_{ko}(\beta)$. As a consequence of the reciprocity theorem, we have $Z_{ij} = Z_{ji}$ and the impedance matrix is symmetric.

Experimental Arrangement

An experimental set-up has been built to test the analytical expressions. It consists of two equal PCB loops of a radius equal to 30 mm. and a negligible thickness and width. These are located in the same plane, at different distances l (Fig. 2) between their centres (from 61 mm. to 90 mm.). Besides, the layer under inductors can be ferrite (insulator with $\mu_r=2000$) or the vacuum at a distance of 1.7 mm, and the layer above inductors may be F114 steel, copper, aluminum or the vacuum at a distance of 4 mm.

The coupling impedance has been carried out by means of a one channel precision LCR-meter E4980A at a frequency range from 1 kHz to 1 MHz. The procedure is to measure the direct series impedance and the opposite series impedance of the two inductor, then, we obtain the values $Z_{\text{direct}} = Z_{11} + Z_{22} + Z_{12} + Z_{21}$ and $Z_{\text{opposite}} = Z_{11} + Z_{22} - Z_{12} - Z_{21}$, therefore, $Z_{\text{direct}} - Z_{\text{opposite}} = 2 \cdot (Z_{12} + Z_{21}) = 4 \cdot Z_{12}$.

Main Results

A comparison between experimental and analytical results can be shown in Fig 3.

Conclusions

A new analitical model of the coupling impedance between inductors placed inside a multilayer media has been developed and experimentally verified for a single turn configuration. This model can be easily extended to n-turns inductors.

In this letter, high-frequency magneto-transport properties in CoFeHfO magnetic oxide nanofilms have been thoroughly investigated by means of transverse incremental permeability (TPR) and magnetoimpedance (MI) measurements. CoFeHfO films with varying thicknesses ($t = 1, 1.5, 1.8$ and $2.4 \mu\text{m}$) were fabricated by oxygen reactive rf-sputtering method. The circle-type film samples were put into a solenoid coil with 10 turns and 10 mm in length. The changes of transverse incremental permeability along the easy and hard axes of the film sample and of MI effect were measured using an rf impedance analyzer HP 4191A in the high-frequency range of 100 – 1000 MHz and a varying external dc magnetic field within 300 Oe. The solenoid coil was located in the perpendicular direction to the external field for measuring transverse incremental permeability. The single-layered film samples with different thicknesses were cut into 15 mm long and 2 mm wide for all MI measurements. The shape of each sample was determined by a mask on the substrate. The experimental analyses revealed that the nanostructure of Co-Fe-Hf-O films prepared consists of α -Fe(Co)-rich bcc nanograins embedded in an HfO_2 -rich amorphous matrix. It is the formation of a granular-type nanostructure that results in the excellent soft magnetic properties of this film. In addition, the insulating HfO_2 -rich amorphous matrix contributes to the high electrical resistivity that significantly suppresses eddy current loss, and, consequently, gives rise to a good high-frequency performance. It is noteworthy that the study of TPR and MI spectra provides deeper physical insights of the complex nature of high-frequency magneto-transport behaviors in the CoFeHfO film material. The results obtained show that the magnitude of TPR values increases with increasing frequency, reaching a maximum value at 710 MHz, and then decreases at higher frequencies. TPR curves measured at the same frequency of 710 MHz along the easy and hard axes of sample are displayed in Fig 1. It can be seen also that the magnitude of TPR increases with increasing film thickness, indicating the increase of magnetic softness. Furthermore, the TPR curves measured along the easy-axis direction shows a single-peak feature at zero magnetic field (Fig. 1a), whereas those measured along the hard-axis direction have a double-peak feature (Fig. 1b). This evidently indicates an existence of magnetic anisotropy and its dispersion in the film. It is worth noting that the width of measured TPR peaks can reflect the distribution of anisotropy field. As can be seen clearly from Fig. 1b, the anisotropy field, corresponding to the peak field (H_k), significantly decreases from 42.6 Oe to 37.8 Oe as the film thickness increases from 1 to $2.4 \mu\text{m}$. This result coincides with that obtained from the magnetization measurements. It has been shown that the decrease of anisotropy field is related to the increase of magnetic softness. Therefore, it is reasonable to conclude that the magnitude of anisotropy field and TPR depends on the degree of the magnetic softness. Apart from this, an asymmetry in the measured TPR curves appears to occur, which is likely to be due to the anisotropy dispersions in relation to the magnetization process. To further clarify the high-frequency magnetic behavior in CoFeHfO material, the high-frequency MI effect in Co-Fe-Hf-O magnetic nanofilms with different thicknesses has been also performed. It is worth noting that, in the investigated frequency range of 100 – 1000 MHz, the MI ratio first increases

with increasing frequency, reaches a maximum at 696 MHz, and then decreases at higher frequencies (see Fig. 2 and its inset, for the $t = 1.8 \mu\text{m}$ film). In addition, the maximum MI ratio significantly increases as the film thickness increases from 1 to $2.4 \mu\text{m}$. It has been demonstrated that the large increase of MI effect at high frequencies is related to the ferromagnetic resonance (FMR) effect as clearly evidenced from the frequency-dependent measurement (both real and imaginary parts) of ac complex permeability. These obtained results indicate that the ferromagnetic resonance plays an important factor for large increase of transverse incremental permeability at high frequencies and, hence the MI effect in CoFeHfO nanofilms.

Width dependence of magneto-impedance in sandwiched films.

D. de Cos, A. Garcia-Arribas, J. Barandiaran
Electricidad y Electronica, Universidad del Pais Vasco, Bilbao, Spain

The magneto-impedance (MI) has been measured for a series of sandwiched Ni-Fe/Au/Ni-Fe samples with different widths. The magnitude and sensibility of the MI are analyzed as a function of both the applied magnetic field and the frequency. Our results clearly show that the width dependence of these figures of merit is mainly a consequence of the external inductance determined by the geometry of the sample.

Sandwiched samples (each layer 500 nm thick) were sputtered onto a glass substrate placed in a magnetic field to induce a transverse anisotropy during the deposition. The wafer was patterned out by conventional photolithography methods and dry-etched to obtain samples 5 mm long and 20, 50, 100, and 200 μm wide. The preparation was completed with a thermal treatment to relax internal stresses.

The MI measurements have been performed using RF techniques: the sample is placed in a 50 Ω microstrip line situated in the central region of a pair of Helmholtz coils. The impedance is obtained from S_{11} parameter measurements made by a network analyzer, after proper calibration and mathematical subtraction of the non desired high frequency contributions of the test fixture [1]. We present measurements results up to 500 MHz where quasi-static processes dominates the MI behavior [2].

The MI curves show the typical two-peak shape that corresponds to well-defined perpendicular anisotropy of $H^k = 7.4$ Oe.

The real and imaginary parts of the impedance are analyzed independently to understand their relevance in the behavior of the magnitude and sensibility of MI. Figure 1 shows the frequency dependence of both real and imaginary parts for the samples with different widths. The impedance shown has been measured for maximum (applied magnetic field equals to the anisotropy field) and minimum (without magnetic field) impedance.

The curves for the real part are very similar for the widest samples (200, 100 and 50 μm). The magneto-impedance corresponding to the real part is, for these samples, ranging between 160 and 180% at 500 MHz. The narrowest sample (20 μm) only reach 38%.

In the imaginary part, the slope that is measured at zero field is caused by the external self-inductance. At the anisotropy field, the impedance grows rapidly at low frequencies, but its slope gradually equals that of zero field at higher frequencies. Consequently, the relative MI is huge at low frequencies but decreases significantly when the frequency increases.

The relevant parameter to determine the performance of the samples is the MI of the absolute value of the impedance. Therefore, the combined behavior of real and imaginary parts must be examined. At low frequency, the imaginary part is small and the impedance is dominated by the real part so, although the MI of the imaginary part is really large, it has no consequences in the MI of the absolute value. On the contrary, at high frequencies, the impedance is dominated by the imaginary part and, although the MI of the real part is really high, the overall MI of the absolute value is not. Using these simple argument, we can explain the behavior of the MI for the absolute value of the impedance as a function of the frequency shown in figure 2: increase while the real part is greater than the imaginary part and decrease after that. The important parameter is then the frequency at which the value of the real parts equals the imaginary parts. This happens at 196, 260, and 295 MHz for the samples 200, 100, and 50 μm wide respectively. In consequence, 50 μm wide sample takes larger MI values since MI is growing longer (up to higher frequencies). And the ultimate rea-

son for this is that the self-inductance of the 50 μm wide sample is smaller, for geometrical reasons, than the ones of 200 and 100 μm samples.

Sample 20 μm wide behaves considerably different and other factors must be taken into account, as flux loss [3]. All those aspects will be discussed in the full length paper.

Annealing effects on the microwave absorption properties of nanocrystalline Fe₇₉Si₁₆B₅ microwires.

M. Han, L. Deng, D. Liang

State Key Laboratory of Electronic Thin Films and Integrated Devices, University of Electronic Science and Technology of China, Chengdu, China

Fe-based amorphous and nanocrystalline wires have been widely reported for their giant magnetoimpedance (GMI) effect, and have been mainly exploited for sensor developments, such as magnetic field sensors, position sensors etc. [1] Recently, there was an ever increasing interest in studying the electromagnetic (EM) wave absorbers due to their applications in anti-EM interference coatings, microwave darkrooms [2]. It is well known that Fe-based nanocrystalline materials can be fabricated by properly annealing amorphous Fe-Si-B alloy: nano scale α -Fe grains are embedded in an amorphous matrix [3]. However, to our best of knowledge, the possible application of Fe-Si-B nanocomposite in EM wave absorber has not been well exploited yet, especially in forms of microwires.

Fe₇₉Si₁₆B₅ microwires were fabricated by the melt extract method. Annealing treatments on magnetic wires under argon atmosphere for 1 hour were carried out at 600 °C and 750 °C respectively. The M-H loops were measured for the heat treated microwires on a vibrating sample magnetometer (VSM). The heat treated microwires were cut into 1 mm, and homogenously mixed with wax (the microwires / wax weight ratio is about 1:2), then the complex relative permittivity ($\epsilon_r = \epsilon' - j\epsilon''$) and the complex relative permeability ($\mu_r = \mu' - j\mu''$) were measured on an Agilent 8720ET Network Analyzer within the frequency range of 1 GHz – 18 GHz.

The morphology of as-prepared microwires with the average diameter of 33 μ m is shown in Fig. 1(a). The DSC curve is shown in Fig. 1(b), and two exothermic peaks are found at 532 °C and 665 °C. The first peak is believed due to the formation of α -Fe nanocrystalline grains. The second peak is due to the formation of non-magnetic borides (Fe₂B), as shown in Fig. 1(c). Magnetic hysteresis (M-H) loops are shown in Fig. 1(d). Both the as-prepared microwires and the microwires annealed at 600 °C show good soft magnetic properties. Their coercivity values are about 5 Oe. However, the coercivity of microwires annealed at 750 °C is about 110 Oe, its larger coercivity is believed due to the formation of non-magnetic phase Fe₂B, which hinders the movement of domain walls. The large permittivity values (for instance, for microwires annealed at 750 °C, $\epsilon' = 45$ at 1 GHz) are believed due to the good conductivity characteristics of microwires. The permeability spectra for the annealed microwires are shown in Fig. 1(e). Interestingly, there are two dispersion peaks for each spectrum. The peak at lower frequency is believed due to the domain wall movement, the other one is believed due to the spin rotation. The EM wave absorbing performances are generally evaluated using the reflection loss (RL) in dB unit. With the measured permittivity and permeability values, we can evaluate their EM wave absorption performances based on the following equations [4]:

$$Z_{in} = Z_0(\mu_r/\epsilon_r)^{1/2} \tanh\{j(2\pi ft/c)(\mu_r\epsilon_r)^{1/2}\} \quad (1)$$

$RL = 20\log[(Z_{in}-Z_0)/(Z_{in}+Z_0)] \quad (2)$, where Z_0 is the impedance of free space; t is the thickness of an absorber; c is the speed of light. As shown in Fig. 1(f), if t is 1.25 mm, the microwires annealed at 600 °C show better absorption performances: for microwires annealed at 600 °C, the minimum RL is -15.8 dB at 15 GHz; while for microwires anneal at 750 °C, the minimum RL is -9.4 dB at 14.33 GHz.

Microwave absorption of amorphous microwires carrying a low frequency ac current.

A. G. Gorriti, I. Carabias, P. Marin, A. Hernando
Instituto de Magnetismo Aplicado, Las Rozas, Spain

There is a growing interest in the study of glass coated amorphous microwires, Fe or Co rich, because they show very interesting magnetic properties with a broadband range of applications. Among others, they present ferromagnetic resonance and therefore absorb electromagnetic energy on the microwave region of the spectrum [1].

These microwires consist of an inner core of an amorphous metallic composition of typically tens of μm coated with glass. They are obtained by an extracting melt-spinning technique, based on Taylor's classical method [2]. A SEM image of a microwire is shown in Figure 1.

Their magnetic properties are strongly dependent on the composition of the metallic core, and the magnetization process on the magnetostriction constant and the magnetoelastic anisotropy induced by internal stresses [3]. These affect the ferromagnetic resonance (FMR) which is responsible for the absorption of microwave energy.

These absorption properties are unique and depend on several factors, such as, composition, diameter relation between the inner metallic core and the glass coat, temperature, applied tension along the wire, applied external low frequency magnetic field, etc. Which enable the use of these microwires in applications ranging from microwave absorbers to magnetic tags. But, to fully develop these applications a deep understanding of the relation between the physical processes and the parameters that affect them is needed.

It is well known that the absorption mechanisms are altered by an applied low frequency magnetic field parallel to the microwire [3]. However, in this communication we want to show that this is also the case when the wire transports an alternating low frequency current.

The microwave absorption was measured inside a microwave anechoic chamber with helical antennas at a frequency of 1.29 GHz. An antenna emitted a circular polarized electromagnetic wave, generated by an ESG Analog Signal Generator, while the other received the signal via an EMC Spectrum Analyzer. At the same time, the microwire transported a low frequency ($f = 10 \text{ Hz}$) alternating current (I). Data was recorded in the time domain and it showed that the microwire modulated the emitted signal with a period equal to $1/f$ (see Figure 3).

The amplitude of the modulation depends on the amplitude of the applied field, it increases with increasing field amplitude up to a value where it stabilizes (the microwire is saturated). Figure 2 shows different modulations for different current intensities, and Figure 3 the amplitude of the modulation versus the intensity of the applied current. In this case, the microwire had a composition of $\text{Mn}_{70}\text{Co}_{69}\text{Si}_{11}\text{B}_{13}$, and the current was sinusoidal. We will also show how the modulation follows other types of current, such as square.

These experiments show a promising future for the absorption of microwaves with microwires.

Emerging Central Lab, Macronix International Co. Ltd, Hsinchu, Taiwan

Magnetic tunneling junctions (MTJs) and pseudo spin valves (PSVs) show great promise for applications in Magnetoresistive Random Access Memory (MRAM), pick-up heads, and magnetic sensors. It is well known that due to the oxidation and diffusion effects, the DC MR ratio of the PSV decreases as the annealing temperature increases. [1]. However, the characteristics of annealing treatment (AT) in PSV are hard to differentiate by non-destructive analysis. Recently, it is shown that the impedance spectroscopy can provide evidences to identify interface or metal layers characteristics by using equivalent circuit analysis [2, 3]. In this study we extend our previous work [4,5] to report on the frequency response features of the magneto impedance (MI) behavior of PSVs with a nano-oxide layer (NOL) after AT.

The PSV (1cm²) with Ta (0.6 nm)/Co-NOL/Co (3 nm)/Cu (5 nm)/Co (1 nm)/NiFe (3 nm)/substrate has been fabricated by e-gun evaporation at room temperature (R_T). The nano-oxide layer was obtained by oxidizing the thin magnetic layers of Co for ten minutes naturally. The sample was subsequently annealed from R_T to 200°C for 30 minutes. The MI behavior was determined by using the HP4194 impedance analyzer with the HP16047D fixture ranging from 100 Hz to 40 MHz.

As the AT temperature increases from R_T to 200°C, the resistance of the PSV with NOL increases from 5.00 to 6.32 ohm and DC MR ratio of the PSV decreases from 5.41 to 0.48 %. The effective capacitance was studied by imaginary part of impedance (Im (Z)) curves, as shown in Fig. 1. Im (Z) reaches a minimum at roll-off frequency (f_{roll}). This f_{roll} is a function of AT temperature, and we find that it increases linearly from 345 to 465 kHz as the AT temperature increases from R_T to 200°C. According to the effective capacitance calculation $f_{roll} = 1 / (2\pi R_{eff} C_{eff})$, the effective capacitance should reversely proportional to the f_{roll} and the estimative values of C_{eff} decrease from 21.8 to 11.8 nF as AT temperatures increase from R_T to 200°C. As plotted in Fig. 2, the coercivity (H_C) of the Co layer is 20 Oe, and H_C of the Co-NiFe layers is 12 Oe in the PSV that deposited at R_T. When the AT temperature increases to 140°C, the H_C of Co shows incoherent in the PSV apparently due to the oxidation in Co layer. The experimental data of f_{roll}, which increases as AT temperature increased from room temperature to 140°C, suggest the increase of the oxidative thickness of Co layer. For the AT temperatures higher than 140°C, it is difficult to distinguish the H_C between Co and Co-NiFe, and this implies that the oxidation reaction extends from Co to Cu layers. This effect could be regarded as two capacitors in serial and as results the effective capacitance decreases as shown in the inset panels in Fig. 2.

In summary, the magneto impedance behavior in the Co/Cu/Co/NiFe pseudo spin valve with a nano-oxide layer after AT has been studied. Its roll-off frequency increases from 345 to 465 kHz, and the effective capacitance decreases from 21.8 to 11.8 nF as the AT temperature increases from R_T to 200°C. We can utilize the equivalent capacitor circuit to explain the NOL behavior with AT. This study shows that the impedance analysis is a useful technique, and its nondestructive measurement is more widely appreciated.

The giant magnetoimpedance (GMI) effect is observed when the impedance of a magnetically soft conductor is measured as a function of frequency of the drive current and the applied external dc field.¹ Technological applications of the GMI effect such as magnetic, current and stress sensors¹ primarily require high impedance variation, high intrinsic sensitivity to dc and ac fields and low intrinsic magnetic noise. The magnitude of the effect, ΔZ , is commonly given by the change of impedance relative to the impedance at saturation. The sensitivity, S (in units of %/Oe or %/T), is proportional to the derivative of ΔZ with respect to the applied dc field. The magnetic noise, MN (in units of T/ $\sqrt{\text{Hz}}$), which is a quantity proportional to the voltage-noise-to-sensitivity ratio, defines the minimum measurable field in 1Hz bandwidth and dictates sensor performance. In this work, the experimental and theoretical behaviour of S and MN are analyzed as a function of frequency and applied fields, including the effect of a dc bias current, for a Co-based magnetic conductor. A procedure to obtain the external parameters yielding the highest S and minimum MN is outlined.

We have recently proposed a simple model to evaluate the GMI MN and S in the MHz regime of anisotropic magnetic wires.² The model accounts for a biasing dc circumferential field, H_{bias} , which is included in the internal field of a single domain cylindrical magnetic conductor. For given frequency, H_{bias} and easy axis direction, S is evaluated as a function of the external axial dc field, H_{ext} . The field yielding the maximum sensitivity (S^{max}), $H_{\text{ext}}^{\text{max}}$, is determined, defining the sensor working point. The MN is then evaluated at $H_{\text{ext}}^{\text{max}}$. For helical magnetic structures having the easy magnetization axis close to circumferential, calculations show that both S^{max} and MN (at $H_{\text{ext}}^{\text{max}}$) decrease for increasing H_{bias} .² The field H_{bias} essentially increases the internal field, which effectively makes the wire magnetically harder and hence, less sensitive to the driving signal when H_{ext} is applied.

Calculated normalized sensitivity, Λ , as a function of H_{ext} and H_{bias} at 10MHz for a 35 μm diameter is presented in Fig. 1. The quantity Λ is given by $\Lambda = H_k S$, where H_k is the anisotropy field of the wire and $S = d\eta/dH_{\text{ext}}$. $\eta = (\xi\mu_t^{1/2} - 1)\cos^2\theta$, ξ is a function of the wave vectors and material parameters,² μ_t is the transverse permeability and θ is the angle between the static magnetization direction and the direction of H_{ext} . The permeability depends on frequency, internal field and magnetic damping. The parameter values used in the calculations are typical for Co-rich amorphous wires. Also, we have used $H_k = 1.4\text{Oe}$ and an easy axis angle of 72° (relative to the axial direction) in the calculations. We observe in Fig. 1 that for this frequency and easy axis angle, S broadens with S^{max} (black points) decreasing when H_{bias} is applied (see also broken lines A and B), as a consequence of the increase of the internal field.

This may not be the case for a wire with an axial easy axis. Figure 2 shows experimental results of $\Delta Z/R_{\text{dc}}$ and S from the measurement of the impedance of an as-cast Co-based wire as a function of H_{ext} , when the wire was submitted to a dc bias current, i_{bias} . The impedance was measured in a HP 8753B Network Analyzer (NA). For the i_{bias} , injected into the device, we used the bias input of the NA. The experimental sensitivity shown in Fig. 2 was then obtained from the numerical derivative of the impedance versus field curve. In Fig. 2a, $\Delta Z/R_{\text{dc}}$ and S vs. H_{ext} at $f=10\text{MHz}$ and 100MHz for $i_{\text{bias}}=20\text{mA}$ are shown. This value of i_{bias} is equivalent to a $H_{\text{bias}} \sim 2\text{Oe}$ at the surface of the wire,

which is close to the H_k of this sample. Figure 2b shows S vs. H_{ext} at $f=100\text{MHz}$ for $i_{\text{bias}}=40\text{mA}$, 20mA and 4mA . These results show that there are optimal frequency and dc bias conditions to maximize the sensitivity. The high S^{max} for a non-zero H_{bias} opens the possibility for the observation of very low values of MN predicted by the theory.²

In this work, the behavior of S and MN are analysed and compared with experiment at frequencies up to 500MHz on Co-based amorphous wires.

Electronics and Optoelectronics Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan; 4. Institute of Physics, Chinese Academy of Sciences, Beijing, China

Magneto impedance (MI) in magneto tunneling junctions (MTJ) has been extensively studied in recent years [1, 2]. The equivalent circuit model composed of a resistance component and two sets of parallel resistance (R) and capacitance (C) components in series, has been utilized to describe the individual impedance contribution from lead of cross pattern, barrier and interface [3]. Therefore, in this study we extend our recent work to investigate a MTJ with different thicknesses of AlOx by means of a non-destructive method - impedance spectroscopy and use mathematic method to predict high frequency behavior of MTJ by equivalent circuit.

The MTJ with structure of Ru (5nm)/Cu (10nm)/Ru (5nm)/IrMn (10nm)/CoFeB (4nm)/Al (x = 0.8, 1.1, or 1.2 nm)-oxide/CoFeB (4nm)/Ru (5nm), which was deposited on Si/SiO wafer by using Magnetron Sputtering System with its junction area of 6μm x 6μm. As an example, its structure and equivalent circuit are shown in Fig. 1 for sample with x = 1.2 nm. The frequency was raised to 40 MHz, and the magneto impedance, $MZ = |Z|e^{i\theta} = R + iX$ in which $X = XL - XC$, of an MTJ device was studied. The MZ ratio is defined as $100\% \times (|MZ|_{AP} - |MZ|_P) / |MZ|_P$, where the subscript P (AP) stands for the parallel (anti-parallel) magnetization orientation state of the MTJ. The magneto resistance ratio (MR) and magneto reactance ratio (MX) are all defined similarly. In fact the whole system contains non-ignorable parasitic inductance and capacitance from wires, and these terms have effect on the shift of resonant frequency. However, these sensing wires do not have any contribution to the MI, and can not prevent us from analyzing general MI phenomena. The AC behavior was determined by using the HP4194 impedance analyzer with the 16047D fixture. A two-point contact was used in a frequency range from 100 Hz to 40 MHz with an electromagnet which supplied a dc field up to 500 Oe.

From our experimental data, the real part of the impedance value at the crossover frequency (fc) at which the real part of the impedance in the parallel state is equal to that in the anti-parallel state, is a single value for samples with x = 1.2 and 1.1 nm. However, as shown in Fig. 2, the resistance difference between the anti-parallel state and the parallel state (RAP-RP) as a function of the frequency between 100Hz to 40MHz for sample with x = 0.8 nm behaviors like a damping oscillating, and its amplitude decreases as frequency increases, which is quite consistent with the calculated value based on the Maxwell-Wagner model due to the reduction of the barrier thickness. From the frequency dependence of the imaginary part of impedance (XAP, XP) for the MTJ in the parallel and anti-parallel states, the effective capacitance increases from 64.10 to 168.81 and 184.90 pF as the barrier thickness decreases from 1.2 to 1.1 and 0.8 nm, respectively. This means that the effective thickness of barrier decreases which cause the effective capacitance increases.

In summary, from the frequency dependence of the magneto impedance for the MTJ in the parallel and anti-parallel states. The RAP and RP curves decrease with increasing frequency, which indicates that the MTJ includes a significant capacitance effect. A Maxwell-Wagner model capacitor consisting of dielectric material with the equivalent circuit theory has been used to analyze our experimental data. We have shown that with an AC current in MTJ, the magnetic behavior can be switched by both the barrier thickness and the driving frequency.

Development of thin microwires with enhanced magnetic softness and GMI.

V. Zhukova², M. Ipatov¹, J. Gonzalez¹, J. Blanco², A. Zhukov^{1,3}

1. Dept. of Phys. Materials, Basque Country University, San Sebastian, Spain; 2. Dpto. de Física Aplicada, EUPDS, Basque Country University, San Sebastian, Spain; 3. TAMAG Ibérica S.L., Parque Tecnológico de Miramón, Paseo Mikeletegi 56, 1 Planta., San Sebastian, Spain

Ferromagnetic metallic glass coated microwires (usually of 15-30 μm in diameter) exhibit a number of outstanding magnetic properties such as magnetic bistability and GMI effect [1-3]. Recent studies allow improving of magnetically soft properties and GMI effect of glass coated microwires but keeping the microwires diameter generally above 10 μm [1,2]. The demagnetizing factor affects the domain structure and magnetic properties when the geometric ratio of microwire diameter to its longitude becomes low enough [3]. Therefore the development of magnetically soft microwires with reduced diameter (below 10 μm) is quite important for micro-miniaturized sensor application [4].

In this paper we studied the GMI effect (GMI ratio, $\Delta Z/Z$, and the off-diagonal impedance tensor component $\xi_{\phi z}$) and hysteretic magnetic properties in ultra-thin amorphous glass-coated microwires with nearly-zero and negative magnetostriction constant and metallic nucleus diameter ranging within 6 and 16 μm have been systematically studied.

Both $\Delta Z/Z$, and hysteresis loops of nearly-zero $\text{Co}_{67.1}\text{Fe}_{3.8}\text{Ni}_{1.4}\text{Si}_{14.5}\text{B}_{11.5}\text{Mo}_{1.7}$ microwires magnetostrictive exhibit strong sensitivity to the ratio, ρ , the metallic nucleus diameter to the total microwire diameter. The hysteresis loops exhibit low coercivity (generally below 15 A/m) with well defined magnetic anisotropy field, H_k (see Fig.1a). H_k increases when ρ decreases (see Fig.1b).

Field dependence of the off-diagonal voltage response of nearly zero magnetostriction ($\lambda_s \approx -3 \times 10^{-7}$) $\text{Co}_{67.1}\text{Fe}_{3.8}\text{Ni}_{1.4}\text{Si}_{14.5}\text{B}_{11.5}\text{Mo}_{1.7}$ with metallic nucleus diameter of 6.0, 7.0 and 8.2 μm exhibits anti-symmetrical shape with almost linear growth within the field range from $-H_m$ to H_m associated with the anisotropy field (Fig.2a).

DC and even pulsed current significantly affects the off-diagonal MI curves of $\text{Co}_{67.1}\text{Fe}_{3.8}\text{Ni}_{1.4}\text{Si}_{14.5}\text{B}_{11.5}\text{Mo}_{1.7}$ microwires with vanishing magnetostriction constant: voltage pulse with the peak value above some critical value reduces the linear region (Fig.2b). Under DC current annealing the H_m decreases from 480 A/m in as-cast state to 230 A/m after 5 min annealing with 50 mA current.

High negative magnetostriction microwire $\text{Co}_{74}\text{B}_{13}\text{Si}_{11}\text{C}_2$ ($\lambda_s \approx -10^{-6}$) with metallic diameter of 10 μm possesses hysteretic off-diagonal MI curve in as-prepared state. DC joule heating affects the character of the magnetic field dependence of $\xi_{\phi z}$ for $\text{Co}_{74}\text{B}_{13}\text{Si}_{11}\text{C}_2$ microwire: the hysteretic MI curve transforms into the unhysteretic one with large enough nearly-linear region.

The obtained results allow us to tailor the microwire magnetic properties for its application in magnetic sensors through the selection of their composition and/or thermal treatment conditions.

Dependence of magneto-impedance on magnetic states in manganese.

J. Li, H. Chou, C. Lin

Department of Physics and Center of Nanoscience, National Sun Yat-sen University, Kaohiung, Taiwan

There has been much interest in the magneto-resistive behavior of the manganese oxides, due to the remarkable reduction in the resistivity by the application of a magnetic field. To our acknowledgement, few works of higher frequency transport properties of manganese oxides have been systematically reported [1,2]. Experimental results have demonstrated that the magneto-impedance at higher frequency can be sensitively affected by magnetic states on the sintered manganese oxides, called giant magneto-impedance (GMI) effects. In this work, the impedance spectroscopy of $\text{La}_{0.67}\text{Sr}_{1.33}\text{MnO}_4$ and $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ were applied to characterize the ac properties behind and after Curie temperature (T_c). Our work provides further understanding of the dielectrics variation during the phase transition from an antiferromagnetic (AFM) insulating phase or a ferromagnetic (FM) metallic phase to a paramagnetic (PM) insulating phase.

In this study, thin films of $\text{La}_{0.67}\text{Sr}_{1.33}\text{MnO}_4$ and $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ were deposited on SrTiO_3 (001) substrate by an off-axis RF sputtering method [3]. The impedance spectra were measured from 125K to 291K by using HP4284A network analyzer, in the frequency range of 20Hz to 1MHz.

Fig.1 shows the frequency dependence of the imaginary component of the complex impedance, $Z(f) = R(f) + iX(f)$, for the $\text{La}_{0.67}\text{Sr}_{1.33}\text{MnO}_4$ thin film in $T \sim 125\text{K} - 291\text{K}$. For $T < 156\text{K}$, the resistive component (R) and the absolute value of the reactive component ($-X$) decrease monotonically with frequency and exhibits negative curvatures for the entire frequency range. When $T > 156\text{K}$, the curvature of $R(f)$ for exhibits a plateau at low frequency and decreasing monotonically at higher frequency while the curvature of $-X(f)$ shows an up-down bump with maximums at certain frequencies. These bumps intensities decrease and the frequency of the peak intensity increase with the frequency, as shown in the inset. The evolution of the impedance spectra is coincident with the AFM phase transition of $\text{La}_{0.67}\text{Sr}_{1.33}\text{MnO}_4$ thin film, in which the antiferromagnetic (AFM) to paramagnetic (PM) insulating phase transition appears within $T \sim 156 \sim 185\text{K}$. [4]

The high frequency impedances of $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ thin film are plotted in Fig. 2. The reactive component (X) appears an increasing curve as a function of frequency for $T < 329\text{K}$. When at $T > 329\text{K}$, the X decreases with raising frequency (as shown in the inset). The evolution of the impedance spectra is in correspondence to the FM-PM transition at $T \sim 329\text{K}$. The observed diverse feature of spectra on $\text{La}_{0.67}\text{Sr}_{1.33}\text{MnO}_4$ and $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ may be correlated with different nature of FM/PM and AFM/PM states.

These magneto-impedance spectra are further analyzed based on an equivalent circuit that composes of resistances (R) and capacitances (C) to the grains and grain-boundaries. The results of our work may provide a fundamental understand of the higher frequency conduction in manganese oxides. Details of the analysis will be presented in the conference.

Temperature Dependence of Magnetoimpedance and Anisotropy in Nanocrystalline Finemet Wire.

B. Hernando¹, J. Olivera¹, M. Sánchez¹, V. M. Prida¹, R. Varga²

1. Física, Universidad de Oviedo, Oviedo, Spain; 2. Inst. Physics, Fac.Sci., UPJS, Park Angelinum, Kosice, Slovakia

The study of the temperature dependence on magnetoimpedance (MI) effect is important for controlling the thermal stability of MI-based sensor devices in amorphous magnetic materials [1]. The MI effect in ferromagnetic materials describes the change of the material's impedance due to the variations on the penetration depth of an ac current flowing across the sample under the influence of the static applied magnetic field [2]. An Fe_{73.5}Cu₃Nb₁Si_{13.5}B₉ (Finemet) wire fully nanocrystallized after one hour annealing at 565°C [3], with 133 µm in diameter and 1.5 cm in length, was chosen for the temperature measurements of MI effect by employing a cryogenic chamber, where the temperature of the sample can be varied from 80 to 340 K. The MI effect has been collected as a function of a dc magnetic field $-5000 < H_{dc} < 5000$ A/m, with a driving current amplitude of $I_{rms} = 5$ mA and a frequency of 1kHz, for all measured temperatures. It has been found that MI effect exhibits a characteristic temperature dependent behaviour in these samples, where a double peak is obtained at low temperature (Fig. 1 a), while it changes into a single peak shape near room temperature (Fig. 1 b). A peculiar asymmetry in the double peak behaviour as a function of the applied magnetic field is clearly observed in the low temperature regime, in comparison with other previously studied wires [1], since the highest peak of the MI maximum is found in the direction of the static field at which the sample was saturated, meanwhile the smaller maximum is found in the opposite magnetic field direction. These measurements can be explained in terms of competition between different existing anisotropies in the sample, taking into account the revised core-shell model [4]. This investigation brings information about the thermal evolution of magnetization dynamics, anisotropy, and the magnitude of the MI effect in this kind of nanocrystalline ferromagnetic samples.

Asymmetrical magnetoimpedance in CoFeSiB/CoNi layered microwires.

J. Torrejon¹, G. Badini¹, L. V. Panina²

1. Magnetism, ICMM (CSIC), Madrid, Spain; 2. School of Computing, Communication and Electronics, University of Plymouth, Plymouth, United Kingdom

Magnetoimpedance (MI) is an expanding area of current research finding applications in magnetic sensor technology and smart sensory composites. Various soft magnetic materials such as amorphous or nanocrystalline wires and ribbons show large change in high frequency impedance for a characteristic fields of few Oe, having a sensitivity in the range of 50-100%/Oe. This high sensitivity makes MI elements very attractive for low field detection. However, typically, MI characteristics are essentially non linear near the zero field point with strongly reduced sensitivity. Therefore, the sensor operational region should be shifted by applying a dc bias field or current. This could be disadvantageous for many practical applications, for example, where low energy consumption is required or in smart sensory composite with remote interrogation. Establishing asymmetrical magnetic configuration helps to improve linearity and reduce the needed dc bias [1]. Here we report asymmetrical MI in CoFeSiB glass coated amorphous microwires with electroplated semi hard CoNi outer shell. This additional magnetic layer creates a magnetostatic bias and also modifies the wire magnetic anisotropy. The MI characteristics have essentially linear portion near zero field with sensitivity up to 20%/Oe.

Multilayer microwire samples were prepared by combining Taylor-Ulitovsky method to produce $(\text{Co}_{0.94}\text{Fe}_{0.06})_{72.5}\text{Si}_{12.5}\text{B}_{15}$ amorphous core (17.4 μm in diameter) coated with glass (12.1 μm), with further sputtering Au nanolayer (30 nm) and electroplating $\text{Co}_{90}\text{Ni}_{10}$ magnetic layer. The inner core with small negative magnetostriction and soft magnetic properties showed large MI. The Au nanolayer played a role of electrode/substrate for subsequent electroplating a semi hard magnetic shell the thickness of which was varied in the range of 0-12 μm by changing the electroplating parameters [2]. Changing the thickness of CoNi layer allows controlling the magnetostatic bias and induced helical anisotropy [3]. The samples were investigated at low-field with the outer shell in a demagnetised state and magnetised in positive and negative sense with the field of 0.5-1 kOe. The dc magnetization behavior of the samples was investigated by measuring B-H loops by VSM method and hysteresis modeling to obtain anisotropy and magnetostatic field characteristics (no shown here). The loops are shifted in a positive or negative direction depending on the CoNi layer magnetization and reveal a slightly helical anisotropy with the angle of about 15° with respect to the circumference.

The MI characteristics of multilayer wires were found from measurements of S_{11} parameter with the help of vector network analyzer HP8753E sweeping in frequency from 1 MHz to 500 MHz. The sample is housed as a central conductor in microstrip line of 50 Ω characteristic impedance with SMA connectors at both ends, one of which is loaded with a precision 50 Ω termination and the other is connected to the VNA. The outer shells of the samples are shorter than the inner soft magnetic core to exclude them from electrical connections. The test fixture was placed inside a long solenoidal coil producing a magnetic field of increasing values up to 50 Oe.

Figure 1a shows the MI plots at 50 MHz for a multilayer microwire with $t_{\text{CoNi}} = 3 \mu\text{m}$ when the hard magnetic layer is in a demagnetised and magnetized state. The insert shows the same plots at a larger field scale. For demagnetized CoNi layer, the MI characteristics show two symmetrical peaks typical of a transverse anisotropy. When this layer is magnetized in a high field (± 1 kOe), the MI plots reveal asymmetry and a shift due to induced magnetostatic bias field. It also appears that the anisotropy in the inner soft magnetic layer depends on the magnetization state of the outer

hard magnetic layer. Increasing the thickness of the hard magnetic layer increases the biasing effect as shown in Fig.1b, however, the induced anisotropy also increases which reduces the sensitivity. At optimal conditions of $t_{\text{CoNi}} = 3 \mu\text{m}$, the MI characteristics are almost linear near the zero sensed field with the nominal change in impedance of about 50% in the field range of -1 Oe -2.5 Oe. The obtained linear highly sensitive MI characteristics in layered microwires without using any external dc bias demonstrate that this new family of MI materials can be very promising in magnetic sensor applications

Role of the interdomain wall in the giant magneto-impedance effect of thin microwires.

H. Chiriac, T. Óvári, S. Corodeanu

National Institute of Research and Development for Technical Physics, Iasi, Romania

Nearly zero magnetostrictive glass-coated amorphous microwires with metallic nucleus diameters ranging between 1 and 40 μm and the glass coating thickness between 1 and 30 μm , display excellent soft magnetic properties and an appropriate domain structure for a sensitive giant magneto-impedance (GMI) response, suitable for sensor applications [1].

The interdomain wall that separates the main regions of the magnetic structure in these microwires has been recently investigated [2]. It has been shown that the interdomain wall between the inner core (IC) and the outer shell (OS) has a large width in case of nearly zero magnetostriction, such as in $\text{Co}_{68.15}\text{Fe}_{4.35}\text{Si}_{12.5}\text{B}_{15}$ microwires. In this case, the interdomain wall reaches within the region that responds in the high frequency GMI effect, region determined by the skin effect through the magnetic penetration depth. The GMI effect has been recently employed as an experimental method in the investigation of the interdomain wall in thicker microwires, i.e. with the metallic nucleus diameter around 20 μm [2], microwires that have been also analyzed for the optimization of the GMI effect [3].

The aim of this paper is to investigate the role of the interdomain wall in the GMI effect of thin microwires, i.e. with the metallic nucleus diameter close to 1 μm . The importance of such thin microwires emerges from their potential applications as sensors in spintronic devices.

With this aim, we prepared glass-coated amorphous microwires with the nominal composition $\text{Co}_{68.15}\text{Fe}_{4.35}\text{Si}_{12.5}\text{B}_{15}$, with the metallic nucleus diameter of 1.5 μm and the glass coating thickness of 7.5 μm . GMI measurements have been performed at frequencies of the ac driving current between 10 and 500 MHz on both as-cast samples and on samples with the glass coating completely removed by chemical etching.

The GMI ratio, defined as the difference between the impedance at the measuring field and the impedance at the maximum field divided by the latter, displays a maximum at each frequency in the case of as-cast samples, its position being symmetric with respect to the applied dc field. The most sensitive response is obtained at 100 MHz. Such maxima are linked to the transverse anisotropy field, i.e. once the applied field overcomes it, the GMI response is the largest since the magnetic moments are free to follow the circumferential field created by the ac driving current.

Glass removal leads to a significant change in the shape of the GMI curve. The most sensitive response is again obtained at 100 MHz. Fig. 1 shows the GMI response at 100 MHz for an as-cast sample and for the same sample after glass removal. The GMI ratio decreases monotonically with the applied field, without going through a maximum. This change in the GMI behavior is associated with the important stress relief caused by glass removal. Consequently, the transverse anisotropy field decreases abruptly, becoming almost negligible.

In order to fully understand this behavior, one has to consider the presence and the parameters of the interdomain wall, and the changes these parameters suffer as a result of glass removal, due to the large width of the wall in these microwires. Therefore, we have calculated the position and the width of the interdomain wall in the as-cast state, as well as their changes with glass removal.

The as-cast microwire has a calculated interdomain wall width of 175 nm located between the radial coordinates 0.686 μm and 0.861 μm . This leaves space just for an extremely thin OS (less than 40 nm), but nevertheless with a quite large circumferential anisotropy. Glass removal leads to a drastic decrease of the axial tensile stress, which practically results in the expansion of the interdomain wall with almost 30% of its initial width and in the vanishing of the thin OS. The observed

GMI behavior of the microwire with the glass coating removed is perfectly plausible under these circumstances.

Summarizing, the characteristics of the GMI response of thin microwires are a consequence of the interplay between the magnetic penetration depth, the location and width of the interdomain wall, their changes with glass removal, as well as of the general characteristics of the microwire's domain structure (e.g., presence or absence of the OS and OS thickness).

Development of an Axial-flux Spindle Motor for the Slim Optical Disc Drive.

G. Yan¹, G. Huang¹, H. Wang¹, L. Hsu²

1. Micro/Meso Mechanical Manufacturing Section, Metal Industries Research & Development Center, Kaohsiung, Taiwan; 2. Electric Motor Technology Research Center, National Cheng Kung University, Tainan, Taiwan

I. INTRODUCTION AND MOTIVATION

Slim optical disc drives are popular and manufactured to be very thin for use in portable terminals such as notebook computer. However, there is still a strong demand for the optical disc drive with thinner thickness. To accommodate this demand, the spindle motor is one of important elements that require high efficiency and compact size. As the height of the optical disc drive is reduced, it is more difficult to design a spindle motor to satisfy the above requirements with radial-flux type. Therefore, an axial-flux motor has been proposed to achieve smaller size due to its low profile.

As shown in Fig. 1, the proposed motor is composed of a rotor with high-energy magnet, NdFeB, and a stator with windings piled up on PCB board. Besides, there is no cogging torque due to the slotless base plate. In this study, the axial-flux motor is chosen as 3 phases, 6 winding coils and 8 poles. Under the design procedure, the parameters of the motor structure are determined by the equivalent magnetic circuit. FEA, using ANSOFT Maxwell software, is then applied to verify the design calculations and result.

II. MOTOR DESIGN

The main issue of the structure design is to minimize the height in the axial direction. Fig. 2 shows the mechanical structure of the proposed motor. The height from the bottom plate to the upper cover is reduced to 4.2mm, where the conventional one has the height about 6.8mm.

In the electromagnetic design, the torque constant is the major design consideration. For the application of the slim optical disc drive, the expectant value is about 3.5 mNm/A. A three-dimensional finite-element analysis is employed to calculate the flux density distribution in the steady-state as illustrated in Fig. 3. Local hot-spots in the flux density appear in the rotor yoke above the interpole regions. The average flux density in the air gap is about 0.4~0.5 Telsa. This leads the number of the turns per coil should be greater than 30.

III. POTOTYPING AND BERIEF CONCLUDSION

From the design outlined in the previous section, a prototype is constructed as shown in Fig. 4. The comparison between the prototyped motor and the conventional one is also shown in this figure. In this paper, the decrease in size of this motor, as compared with the conventional one, is up to 55%. An experimental device to measure the characteristics of the developed motor by using the forcemeter is setup. After the spindle motor reaches the highest speed under no load condition, the load weight is applied. Then, current and speed are measured with the supply voltage of 5 V. According to the experimental measurement of the torque-current curve, the torque constant is about 3.2mNm/A. This is 8.5% less than the expectant value but acceptable, while the rated speed is about 6000rpm. With the improvement of the tilt and axial repeatable run-out (RRO) characteristics, the developed motor has great potential for the novel optical disc player applications in the near future.

Developments of a direct driven linear tubular generator for wave energy extraction.

C. Liu¹, S. Yan¹, C. Lin¹, H. Lin¹, M. Lai¹, C. Hwang²

1. Electrical Engineering, National Sun Yat-Sen University, Kaohsiung, Taiwan; 2. Electrical Engineering, Feng Chia University, Taichung, Taiwan

Introduction:

The ever increasing demands for generating electricity from various carbon-free renewable energy sources have drawn the attentions of developing appropriate mechanical/electrical conversion systems that can fulfill these special requirements. A linear tubular generator (LTG), with slotless stator windings and quasi-Halbach mover permanent magnet (PM) arrangement that can operate in reciprocating manner to incorporate with the available wave energy extraction mechanisms, will be reported in this paper.

Though the design concepts of linear tubular electric machines are quite common [1], detailed electromagnetic characteristic investigations will be required at the objective operational modes and mechanical inputs. The stator winding flux linkages contributed from those ring-shape mover PMs with radial, axial, and quasi-Halbach flux directions will be respectively calculated from three-dimensional (3-D) finite element method (FEM), and the induced voltages at the specific wave energy input patterns will then be devised. Based on these system electromagnetic characteristics and the offshore site measurement data, applicability of the proposed LTG for wave energy extraction can then be assessed.

The Linear Tubular Generator:

Figure 1 shows the conceptual structure of a LTG, and the three possible mover PM arrangements are illustrated in Fig. 2. As the main flux direction in the mover is determined by the magnetization of PMs, the interaction rates and directions between stator windings and mover fluxes will dominant the generator voltage supplies. With a guided flux path through the mover PMs, investigations showed that the LTG with quasi-Halbach mover PM array will provide better overall performance. The 3-D meshes, flux density distribution, and stator induced flux linkages of this arrangement are illustrated in Fig. 3.

Operation and Applicability Evaluations:

Based on the long-term site measurements and the wave energy conversion mechanisms [2], the offshore wave energy distribution surrounding Taiwan and the buoy velocity pattern at the corresponding northeast area are illustrated in Fig. 4. By combining the flux linkages and the damped velocity patterns, with $|V(t)| = |d/dt(\lambda(x,t))| = |v(t) \cdot d/dx(\lambda(x,t))|$, the voltages that are induced from the proposed LTG with quasi-Halbach rotor PM array can be devised and shown in Fig. 5. Evidently after a power conditioning device, the generated electricity can be stored and supplied to the utility system through sub sea cables. From such preliminary assessments, applicability of the proposed LTG for wave energy extraction can be validated.

Mechanical resonance in non-oriented electrical steels induced by magnetostriction under pwm excitations.

S. Somkun, A. Moses, P. Anderson

Wolfson Centre for Magnetics, Cardiff University, Cardiff, United Kingdom

Magnetostriction (MS) is a source of acoustic noise and vibrations in induction motors [1]. The acoustic noise can reach its peak if the resonance occurs [2]. Magnetostriction-induced mechanical resonance in electrical steels commonly used in motor cores has been recently studied [3]. In the case of a PWM inverter-fed induction motor, there are high frequency components in the flux density (B) waveform, which may resonate [4]. In this work, non-oriented (NO) electrical steels under PWM excitation are studied and the effect of mechanical resonance is also taken into consideration, which could be useful for noise prediction during the motor design process.

Firstly, a strip of M400-50A NO steel 30 cm long and 3 cm wide was magnetised under sinusoidal waveform at 1.0 T peak flux density (B_p) from 500 to 4000 Hz. One end of the strip was clamped, while the displacement was measured at the other end with the aid of a single point laser vibrometer [3]. MS was calculated as the ratio of the displacement to the magnetic path length. At the magnetised frequency of 2250 Hz, the mechanical resonance occurs at 4500 Hz, which is twice of the magnetised frequency. The averaged value of peak to peak magnetostriction (MS_{pp}) was around 21.54 microstrain ($\mu\epsilon$), 14 times higher than that at 500 Hz.

Secondly, PWM waveforms were applied to the strip at $B_p = 1.0$ T. The relation between modulation index (m_i) and fundamental frequency (f_o) was set similar to that in a commercial inverter, which $m_i = 0.5$ at $f_o = 25$ Hz and $m_i = 1.0$ at $f_o = 50$ Hz. The switching frequency (f_{sw}) was selected as either 1687 Hz or 2250 Hz. MS_{pp} under PWM excitations are higher than that under sinusoidal excitation both at $f_o = 25$ and $f_o = 50$ Hz as shown in table 1. MS_{pp} at $f_{sw} = 2250$ Hz is higher than that at $f_{sw} = 1687$ Hz due to the effect of the resonance on the sample. There is significant fluctuation in the butterfly loops of MS when the switching frequency is equal to the resonance frequency even though the amplitude of B is lower than that at 1687 Hz as shown in figure 1. Figure 2 shows closer views of spectrum analysis of B and MS. High frequency components of MS are the same as those of B because the ripples in B do not change the sign of MS. At $f_{sw} = 2250$ Hz, the highest frequency cluster happens at 4500 Hz, which is equal to the resonant frequency, with the peak value around 0.06 $\mu\epsilon$.

MS_{pp} under PWM excitation can be up to 28% higher than that under sinusoidal excitation if the switching frequency matches the resonant frequency of the material. A small value of B can amplify very high value of MS if resonance occurs. Although this experiment was conducted on a single strip, similar effects would be expected in a motor core with different resonant frequencies. Large acoustic noise could be created if the switching frequency of the inverter coincides with the resonant frequency of the motor core.

1. Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, China; 2. School of Automation, Shanghai University, Shanghai, China

I. INTRODUCTION

Compared with mechanical gears, magnetic gears have many advantages such as free from lubrication, inherent overload protection, no mechanical fatigue, low noise and high efficiency. However, due to its poor torque density, the traditional magnetic gear has not received much attention. Recently, a concentric magnetic gear topology has been proposed, which can produce high torque density [1]. However, the 2D-FEM analysis results exhibited serious errors with respect to the actual results. Namely, the measured static torque was about 30% lower than the calculated value in [2]. Although [2] has ever pointed out that such errors might be due to the large end effect, the use of 3D-FEM for such purpose is absent in literature.

In this paper, a 3D-FEM will be newly developed to analyze concentric magnetic gears. The key is to adopt the scalar magnetic potential so that the required data manipulation and computation can be significantly reduced.

II. APPROACH

For the 2D-FEM, vector magnetic potential is commonly used. However, for the 3D-FEM, if vector magnetic potential is adopted, the unknown variables will be three times the number of nodes since each vector potential has three directional variables. Based on scalar magnetic potential, the number of unknown variables is only the number of nodes of volume meshing [3]. Hence, the required memory and time for data manipulation and computation can be significantly reduced.

The magnetic gear shown in Fig. 1 can be represented by a boundary-value problem as given by: $\nabla(\mu \nabla \phi) = 0$ in Ω ; $\phi = \phi_0$ on S_1 ; $\mu(\partial \phi / \partial n) = -B_n$ on S_2 and the interface boundary condition of the PM is given by: $(\mu(\partial \phi / \partial n)) - (\mu(\partial \phi^0 / \partial n)) = \sigma$, where the models of the PM and the calculated region are shown in Fig. 2. Consequently, it can be derived as a set of algebraic equations $[K][\phi] = [P]$ where $[\phi]$ is the vector of unknown scalar magnetic potentials and the contributions of each element to $[K]$ and $[P]$ are calculated by: $k_{ij} = \int_{\Omega} \mu \nabla N_i \nabla N_j d\Omega$, $p_i = \int_{S_2} N_i \sigma ds$. By using the Newton-Raphson iteration method and incomplete Cholesky conjugate gradient method, the above matrix equation can be solved with good convergence.

III. RESULTS

The parameters of the concentric magnetic gear used for exemplification are listed in Table I. Firstly, the magnetic gear is analyzed by the 2D-FEM, and Fig. 3(a) shows the static torque characteristics. Secondly, the developed 3D-FEM is used to analyze the magnetic gear and the static torque characteristics without and with the end effect are shown in Fig. 3(b) and Fig. 3(c), respectively. It can be found that their maximum static torques are very different, which is due to significant leakage flux at both ends of the magnetic gear. For verification, Fig. 3(d) shows the measured static torque characteristic in the outer rotor, which closely matches with Fig. 3(c).

Table II gives a comparison of their maximum static torques and computation times. Although the 2D-FEM can quickly get the result, typically 9 s per computation, the result exhibits a serious error, about 32%. Taking into account the end effect, the newly developed 3D-FEM can provide the result which closely agrees with the measured result, less than 7% error. Due to the use of scalar magnetic potential, the developed 3D-FEM computation time is typically 405 s per computation, which is very acceptable. Also, it can be found that the 3D-FEM (without considering the end effect) is

slightly less accurate than the 2D-FEM, which is actually due to different segmentations of the airgaps along the circumferential direction. For the 2D-FEM, the inner and outer airgaps are divided into 450 and 550 segments, respectively; whereas, for the 3D-FEM, the two airgaps are both divided into 264 segments.

Reduction of the Torque Ripple and Unbalanced Magnetic Force of a Rotatory Two-Phase Transverse Flux Machine by Using Herringbone Teeth.

G. Jang¹, H. Ahn¹, J. Chang², S. Chung², D. Kang²

1. Dept. of Mechanical Engineering, PREM Lab., Hanyang University, Seoul, South Korea; 2. Korea Electrotechnology Research Institute, Changwon, South Korea

Transverse flux machine (TFM) has been considered as one of the promising driving machines especially at the low-speed applications because it has higher power density and torque than conventional electrical motors. However, it tends to generate big torque ripple and unbalanced magnetic force due to its inherent complicated structure, and they may result in the magnetically induced vibration and noise. Prior researchers have investigated to reduce the torque ripple and unbalanced magnetic force. Masmoudi et al. analyzed the magnet-skewing of a TFM rotor to reduce cogging torque [1]. But their design generates the unbalanced magnetic force due to the asymmetry of magnet. Jang et al. proposed a TFM without generating the unbalanced magnetic force by using symmetric multi-pair cores [2]. But their design still has big torque ripple. This paper investigates the characteristics of torque ripple and unbalanced magnetic force of a rotatory two-phase TFM due to the teeth geometry by using the 3-dimensional finite element method, and it develops a rotatory two-phase TFM with herringbone teeth to reduce the torque ripple and to eliminate the unbalanced magnetic force.

Fig. 1 shows a rotatory two-phase TFM with the rated speed of 300 rpm. Stator is composed of soft magnetic composite (SMC) to reduce iron loss, and it has upper and lower cores corresponding to phase A and B. Each core has circumferentially 32 teeth up and down, shifted by 1/2 tooth pitch (180 electrical degree, 5.625 mechanical degree). Rotor has 32 pairs of north pole, SMC and south pole, and they are alternatively arranged along the circumferential direction. Rectangular shape of current with the 1,250 Ampere-turns is applied to the coils of each phase.

Full finite element model is developed to analyze the whole motor. The number of 8-node hexahedral element of full model is 647,681. This model is divided every 0.28125 degree in the circumferential direction. ANSYS, a commercial finite element program, is used to solve the magnetic field. Torque and magnetic force are calculated by using the virtual work method every 0.28125 degree while the rotor passes a period of pole pair.

Magnetic field of the electric motors generates the torque ripple which is the major source of noise and vibration. Skew teeth may be one of the possible solutions to reduce the torque ripple. But they may generate the unbalanced magnetic force in the axial direction. This research investigates the magnetic field, torque ripple and unbalanced magnetic force for the five cases, i.e. (1) conventional straight teeth as shown in Fig. 1, (2) skew teeth for phase A and B in same direction, (3) skew teeth for phase A and B in opposite direction, (4) herringbone teeth for phase A and B in same direction, and (5) herringbone teeth for phase A and B in opposite direction. Fig. 2 shows the teeth geometry from the cases 2 to 5.

Fig. 3 shows the torque ripple and the axial unbalanced magnetic force for 5 cases. The skew angle of teeth is 10.43 degrees. Skew or herringbone teeth from the cases 2 to 5 reduce the torque ripple by approximately 43 %, compared with the conventional straight teeth of the case 1. Torque characteristics of case 2 and 3 are identical, and torque ripple of case 4 is the smallest of all. However, case 2 and 3 with skew teeth generate the unbalanced magnetic force in axial direction, because they have asymmetric magnetic field in axial direction. Fig. 4 shows the magnetic field of skew teeth and herringbone teeth. In Fig. 4 (b), herringbone teeth generates the symmetric magnetic field with respect to the mid plane of each core even though upper and lower teeth are shifted by 1/2

tooth pitch. It explains that TFMs with herringbone teeth do not generate the unbalanced magnetic force. This research may contribute to the sound operation of TFMs by reducing the magnetically induced vibration and noise originated from torque ripple and unbalanced magnetic force.

EVALUATION OF INDUCTION HEATING APPLICATION OF LINEAR INDUCTION MOTOR BY USING FEM CALCULATION.

T. Yamada¹, K. Fujisaki^{2,3}

1. Nittetsu Plant Designing Corporation, Futtsu, Japan; 2. Nippon Steel Corporation, Futtsu, Japan; 3. Graduated School of Environmental Studies, Tohoku University, Sendai, Japan

Introduction

Induction heating application of linear induction motor which uses electromagnetic AC field is investigated. Although linear induction motor application to thin steel sheet is usually used for conveyance, it is also considered to be used as induction heating application, because eddy current is generated in steel sheet. However, in this case, since the thin steel sheet is ferromagnetic material, it is expected that the meandering of the thin steel sheet caused by the electromagnetic force in the normal direction is influence on the product quality. Because the normal force is too difficult to handle the linear induction motor and thin steel sheet, the reduction of the normal force is an important problem to apply it to such a process. As shown in Fig.1, the normal force of the linear induction motor consists of a repulsive force caused by Lorentz force and an attractive force caused by magnetization. To evaluate the basic characteristic of linear induction motor, 2D electromagnetic field calculation by means of finite element method (FEM) is typically used as simplified method. However, because the real equipment is 3D model and especially eddy current shows complex behavior, it is necessary for the detailed investigation to evaluate by 3D electromagnetic field calculation. The aim of this study is to evaluate the characteristic of the electromagnetic force in a single side linear induction motor from the point of view of the comparison with 2D FEM calculation and 3D one.

Comparison result

Frequency characteristic of the electromagnetic force in the normal direction calculated by Maxwell stress method is shown in Fig.2. Here, the electromagnetic force calculated from 2D model is converted value by the steel sheet width of the 3D model. The normal force of the both models decreases as the frequency increases and changes from the attractive force to the repulsive force at 2kHz in 2D model and 5kHz in 3D model respectively. As shown in Fig.3, though the repulsive force caused by Lorentz force increases as frequency increases, on the other hand, the attractive force caused by magnetization is considered to be constant at any frequency. Therefore, a crossover frequency which the attractive force and the repulsive force become equal exists in the frequency characteristic [1]. Therefore, the effect of the normal direction is considered to be removed by operating at the crossover frequency. Also, the crossover frequency of the 3D model is large in comparison with 2D one. This reason is considered that the flow pattern of the eddy current in the steel sheet differs between 2D model and 3D model. The eddy current density vector of the 3D model at frequency 20kHz is shown in Fig.4. 2D calculation model of the linear motor assumes only center section in the width direction like enclosed area by dotted line in Fig.4. On the other hand, because the 3D model has edge part of the steel sheet, the eddy current returns at the edge part of the steel sheet. Usually, Lorentz force in the steel sheet operates as repulsive force mode in the normal direction. However, the eddy current which returns around the edge part of the steel sheet makes the steel sheet an electromagnetic force as attractive force mode in the normal direction and the total quantity of the Lorentz force operates as repulsive force is reduced due to the attractive force at the edge part. As a result, it is considered that the crossover frequency of the 3D model becomes large in comparison with 2D model.

Calculation of Stator End-winding Reactance of an Induction Machine Based on Magnetic Energy by 3-D Finite Element Analysis.

R. Lin, A. Arkkio

Helsinki University of Technology, Espoo, Finland

I. INTRODUCTION

This paper illustrates a procedure for calculating the end-winding reactance of an induction machine by 3-D finite element analysis.

II. MODEL AND METHODS

A. Model

According to IEC, the end-winding reactance should be measured when all the rotary parts are removed, so no rotary parts in this model. To analyze the energy, the core region is divided into 4 same parts with equal 10 cm in axial length. The model is shown in Fig. 1.

B. Methods

The simulations use current sources and a time-harmonic analysis. The following equation is solved:

$$\nabla \times [\mathbf{u}(\nabla \times \mathbf{A})] + j\omega \sigma \mathbf{A} = \mathbf{J}, \quad (1)$$

where \mathbf{A} and \mathbf{J} are the complex vectors of vector potential and current density. The number of DOFs to solve is 272944.

Since no rotary parts, the flux is just stator leakage Φ_p , which contains slot leakage Φ_{sl} , tooth-top leakage Φ_{tl} and end-winding leakage Φ_{el} . Correspondingly, the total magnetic energy in the model W_1 consists of slot leakage energy W_{sl} , tooth-top leakage energy W_{tl} and end-winding leakage energy W_{el} . Also, the sum of W_{sl} and W_{tl} is proportional to the axial length l of stator iron core.

Without the end-windings, the energy in parts 1-4 originates only from slot leakage and tooth-top leakage. Then, the energy in each part should be equal since every part is the same.

The end-windings can affect the energy in the iron cores, especially in the core ends. Part 1 is far from the end-windings, so it is assumed that the energy W_1 in part 1 is not affected by the end-windings, which originates only from slot leakage and tooth-top leakage. Hence, the produced energy by the end-windings can be calculated by

$$W_{el} = W_1 - 4W_1. \quad (2)$$

C. End-winding Reactance

The time-average value of magnetic energy W_V in volume V is calculated by

$$W_V = 0.25 \int \text{Re}\{\mathbf{H}^* \mathbf{B}\} dV, \quad (3)$$

where \mathbf{H} and \mathbf{B} are the complex vectors of field strength and flux density.

The end-winding reactance per phase X_{ew} is calculated by

$$X_{ew} = 8\omega p W_{el} / (mI^2), \quad (4)$$

where I is the rms value of current, p and m are the number of pole pairs and phases.

III. RESULTS

A. Flux Density in Core Region

To analyze the end-winding effects, 4 lines parallel to the axial direction are chosen: line 1 in the air, lines 2 and 4 in the stator yoke and line 3 in the stator tooth. Figs. 2 and 3 plot the variation of flux density along these lines.

B. Magnetic Energy

Based on (3), Table I lists the time-average values of energy in different parts of the model.

C. End-winding Reactance

X_{ew} is calculated by (2) and (4). In this model, $p = 3$, $m = 3$ and $I = 270$ A. The calculation result of X_{ew} is 0.0326Ω , and the given experiential value is 0.0248Ω , so the relative error is 31.5%.

IV. CONCLUSIONS

In Figs. 2 and 3, the magnetic field in the ends of iron core is affected by the end-windings. The flux density in part 4 is stronger than in parts 1-3. Besides, Table I shows that the magnetic energy in part 4 is 2.1% larger than in parts 1, 2 and 3, due to the end-windings. Although the relative error between the calculation result and given value is not small, it is acceptable since the given value is based on the rough semi-experiential analytical formula.

The results verify that the end-windings affect the magnetic field in the core ends. And the effects on the flux density are stronger than that on the magnetic energy in the core ends.

Investigation of carrier loss of induction motors considering skin effect in electrical steel sheets.

K. Yamazaki, N. Fukushima

Dept. of Electrical, Electronics and Computer Engineering, Chiba Institute of Technology,
Narashino, Japan

Induction motors driven by PWM inverters are widely applied to the industry as variable speed motors. However, it is well known that the efficiency of the motor often decrease due to the carrier harmonics that cause the harmonic copper and core losses in the motor. The estimation of the carrier harmonic losses at each part of the motor is desired.

Owing to the progress of computers, the electromagnetic field analysis using the finite element method became a powerful tool to estimate the losses of the motors. In most of the analyses, the stator and the rotor cores are modeled as the solid magnetic material without the conductivity and the core loss is calculated in the post process from the time-variation of the flux density obtained by the finite element analysis [1]. In these cases, the axial variation of the flux density within the electrical steel sheet is neglected.

However, when the frequency of the magnetic field is high, it can be considered that the flux concentrates at the surface of the electrical steel sheets due to the skin effect. The frequency of the carrier harmonics of the PWM inverter is kHz order. Therefore, the eddy current analysis considering the axial flux distribution within the sheet will be required for the correct estimation of the core loss caused by the carrier harmonics.

In this paper, we investigate the carrier harmonic losses in the induction motors from both sides of measurement and calculation. In the measurement, the motor is driven by both the PWM inverter and sinusoidal power supply at the same fundamental voltage condition. Then the total carrier harmonic loss is obtained by the subtraction. On the other hand, the carrier losses generated at the primary windings, secondary conductor, stator and rotor cores cannot be separated by the measurement. Therefore, we also introduce the 3-D finite element analysis considering the skin effect of the electrical steel sheets, which can calculate the losses separately. The measured and calculated total carrier harmonic loss is compared to verify the validity.

Fig.1 shows the voltage waveform and included harmonics of the PWM inverter. The fundamental and carrier frequency is 50 and 3.3kHz, respectively. In this case, around the 66i-th ($i=1, 2, \dots$) harmonics are remarkable.

Fig.2 shows the 3-D finite element mesh. The analyzed motor is a 750W cage induction motor. The analyzed region is reduced as half of the electrical steel sheet of the motor. The number of the time-step per one time period is set as 1,024 to consider the carrier harmonics of the PWM inverter correctly. The rotor region is shifted at each time step due to the rotational speed of the rotor.

Fig. 3 shows the calculated eddy current distribution of the electrical steel sheet. It can be seen that the currents increase when the motor is driven by the inverter. Fig. 4 shows the calculated flux density waveform at the teeth. It indicates that the harmonic ripples are concentrated at the surface of the electrical steel sheet due to the skin effect. The waveform at the inside of the sheet is almost sinusoidal.

Fig. 5 shows the calculated and measured carrier harmonic losses. The loss calculated by the 2-D finite element method assuming the uniform flux density within sheet is also shown for the comparison. The result of the 2-D method clearly overestimates the carrier harmonic core losses because it neglects the skin effect. On the other hand, the result of the 3-D analysis agrees well with

the measured results. In addition, it is clarified that the main components of the carrier harmonic losses in the induction motor are the stator and rotor core losses.

Characteristics Analysis of 3DOF Spherical Motor for robotic wrist motor.

S. Won, J. Lee

Electrical Eng., Hanyang University, Seoul, South Korea

The spherical motor for robotic wrist is growingly attracting interest from researchers and engineers who study the automatic control and robotics because it can change its rotating axis orientation arbitrary. Among the spherical motors, the permanent magnet spherical motor has potential to be adopted in a number of areas of robotic applications because it is very simple to implement 3DOF operations [1].

However, the spherical motor has some problems in predicting its characteristics because we have to perform 3-dimensional analysis to calculate the spherical motor torque which has three directional components of basis coordinate axis. 3-dimensional analysis itself is not so difficult but, in this case, the structure of spherical motor is somewhat complicated like Fig. 1, it takes several hours to finish a 3-dimensional simulation. Considering the rotating axis orientation is not fixed, the analysis of spherical motor characteristics takes such a long time compared with ordinary single axis rotating motor.

To solve this problem, we use a novel calculation method of the spherical motor torques and back-emfs at any arbitrary axis with a given magnetic flux density field data by 3D finite element analysis and current values of each coil elements [2]. Using this method, we can calculate the spherical robotic wrist motor torques at any rotating axis and this method saves calculation time dramatically because it needs just one static 3D finite element analysis for getting flux density field data. It is very important to save calculation time because we have to calculate torque vectors and back-emfs at every time step from start to end while the rotor is moving to designated position to predict the behavior of a spherical motor.

To verify this method, we manufactured a spherical motor and compared the simulated values with the measured data. It is found that the simulation values are in good agreement with the measured values, so it is confirmed that the presented method is very useful in analysis of a spherical motor.

Electro-Magnetically Excited Vibration Testing for a Vibro-Acoustic Investigation on PMSMs in Hard Disk Drives.

S. Suwankawin¹, T. Jintanawan²

1. Electrical Engineering, Chulalongkorn University, Bangkok, Thailand; 2. Mechanical Engineering, Chulalongkorn University, Bangkok, Thailand

Acoustic noise recently becomes new criteria for hard disk drive (HDD) design. Noise that generated from the spindle motor partly contributes to the overall noise of HDD. For the fluid dynamic bearing (FDB) motors in HDDs, electromagnetic (EM) forces are the major source of vibro-acoustic noise [1, 2]. The Permanent Magnet Synchronous Motors (PMSMs) for HDD consist of many tiny components, including the motor base and spindle hub. Both structural components are the major paths of noise, because they play an important role for vibro-acoustic transmission. The modal vibration testing on the motor structure is usually performed to explore its inherent vibro-acoustic behavior [1, 3]. For the small-sized PMSMs in HDD and expanded range of the interested audible frequency up to 20 kHz, the vibration testing on the motor with the mechanical excitation [1, 3] might not be appropriate, because the mechanical impulsive forces contain an insufficient energy for exciting the high-frequency modes. The present work therefore proposes a technique of vibration testing on the miniature PMSMs for HDD through the use of sine-swept, EM-excitation. Compared with the conventional mechanical excitation, the EM excitation is more natural to the actual EM forces that are the major noise source in the motor operation.

EM-EXCITED VIBRATION TESTING

With the motor rating of 10 Vp-p and 1.5-A maximum current and the designed bandwidth of 0.1-20 kHz for the EM-excited vibration testing, it is applicable to design the amplifier that functions within these criteria. In this case, the linear power amplifier (200-W-STK4028II model) is used as the V-to-I amplifier. With a low total harmonic distortion (0.4% THD) of STK4028II, a perfectly sinusoidal current is satisfactorily obtained. The use of V-to-I amplifier helps avoid the high-frequency contents due to switching of the inverter.

In the implementation, the sine-swept source signal was supplied by the function generator from Agilent-35670 dynamic signal analyzer (DSA). This signal was amplified with the V-to-I amplifier and then fed to the motor. During the operation, as the frequency swept, the V-to-I amplifier varies the phase voltage accordingly in order to regulate the phase current at the constant value. To validate the effectiveness of the V-to-I amplifier, the spectrum of the phase current for the whole range of audible frequencies (0.1-20 kHz) is illustrated in Figure 1.

For the test setup, the PMSM for HDD is excited by featuring a sine-swept and controlled current with a constant amplitude that supplied by the V-to-I amplifier to only one phase of the motor, ensuring a constant level of EM force at all various frequencies from 0.1 to 20 kHz. The flexural vibrations from both the motor base and the spindle hub are measured at various positions, using the Laser Doppler Vibrometer (LDV). Signals of the measured vibration and the phase current are fed to the DSA to determine the frequency response functions (FRFs).

VIBRO-ACOUSTIC PHENOMENA OF THE PMSMS FOR HDD

The FRFs were compared with the measured sound power spectrum (SPW) of the spin motor in Figure 2. The vibro-acoustic modes and their corresponding natural frequencies can be identified at peaks of the FRFs. With the proposed sine-swept EM-excitation, all the vibro-acoustic modes, especially at high frequencies, can be completely seen. For all measured FRFs, there exist a single mode at ~2.4 kHz and another two groups of the high-density and undistinguished modes at frequency ranges of 7-12 kHz and 14-20 kHz, respectively. Each vibro-acoustic mode can be identi-

fied in the FRFs that measured either at the motor base or at the spindle hub, indicating that the motor exhibits coupled vibrations of the base and hub.

A comparison of both the vibration and sound spectra in Fig. 2 shows that the natural frequencies of all vibro-acoustic modes found in the FRFs closely match with the sound resonance frequencies, i.e. the frequencies where the mountain peaks exist in the sound spectrum.

A Study on the Multi-Objective Optimal Design of Interior Permanent Magnet Synchronous Motor.

K. Kim, J. Lee

Dept. of electrical engineering, hanyang university, seoul, South Korea

1.INTRODUCTION

Traction motors for vehicles such as fuel cell and hybrid electric vehicle are main application area of an interior permanent magnet synchronous motor (IPMSM). The reason for these applications is driving characteristics of high torque performance when starting mode and wide constant power range by field weakening control [1],[2].

In the paper, the multi-objective optimal design of IPMSM is proposed in order to increase high reluctance torque, low cogging torque, low torque ripple and low THD of back EMF. Because there are many design variables related to shape and arrangement of permanent magnet, representative design variables are suggested and optimized by experimental design method with finite element method (FEM) [3]. For the comparison of reluctance torque, the d-axis and q-axis inductances by FEM are calculated. Finally, the prototypes of IPMSM are experimented for the verification of multi-objective design results.

2.OPTIMAL ROTOR DESIGN OF IPMSM

The rotor model with flat type magnet can not have high inductance difference and saliency which means the ratio of q-axis inductance to d-axis inductance just because of difficulty in security of q-axis flux path in the rotor core. Therefore there is limit to increase the reluctance torque. In the paper, in order to improve the performance of reluctance torque of IPMSM, the multi-objective design of V shape magnet model by using Taguchi method is proposed. Fig. 1 shows the representative design variables of V shape magnet model. The variable RL means the ratio of magnet length to barrier length. Each design variable has three levels and noise factor is set as tolerance levels of slot open width. Each rotor model for Taguchi analysis has the same volume of permanent magnet from an economical point of view.

Orthogonal array L9 is used with multi-objective function. The multi-objective optimal design can be performed by using normalized SN ratio and weighting function of each object function. The values of SN ratio according to object functions are normalized by using mean and standard deviation of SN ratio. After that, the optimal values of multi-object function using weighting function are calculated. For the high reluctance torque, the weighting function for maximum torque is decided as 0.5. The weighting functions of emf and torque ripple are set as 0.3 and 0.2, separately. The main effect plot of SN ratio of multi-objective function is shown in Fig. 2. Therefore, optimized design values of V shape rotor can be selected as A3, B1 and C1.

In order to verify reluctance torque, the d and q-axis inductances according to load angle are analyzed by FEM and total torque is separated with reluctance torque and magnetic torque as shown in Fig. 3. Because of high reluctance torque of V shape magnet model over load angle of 110 degree, the total torque of V shape magnet model is superior to that of flat type magnet model. Fig. 4 shows the experimental set for the verification of optimal design results.

3.CONCLUSION

This paper proposed the multi-objective optimal design of IPMSM for the purpose of high torque density and wide constant power region owing to high reluctance torque by experimental design method with FEM.

Auto focusing actuator for mobile camera module can be classified into stepping motor type, ultrasonic wave type and VCM type. Stepping motor type has strengths of being powerful and highly reliable, but has weakness of big in size and high prime cost. Ultrasonic wave motor type is a type operated by micro precision ultrasonic motor made with piezoelectric ceramic, and due to its advantage of making into compact and slim size, it has been developed and researched for auto focusing camera module. However, due to material's hysteresis and problem in reliability with quick abrasion on friction part and problem with impact due to easily breakable material make ultrasonic wave motor type difficult for application[1]. VCM type is fast in response, high in precision, and excellent in size and prime cost aspects, but as it needs continuous power to be fixed on focal point of lenses, it requires relatively larger power consumption, and has weakness of being fragile on impact[2]. Therefore, by making the most of strengths existing type has at the same time, research on actuator that is improved in reliability and advantageous for making into compact size is needed.

In this paper, VCM actuator designed a similar structure with operating theory of hard drive's rotary type actuator. When rotary type VCM actuator rotates with the center of lens as its basis, it makes up-and-down motion by lens guide with cam shape. Therefore, this kind of structure allows advantages of lower power consumption, rugged structure to impact and vibration, and easy to be made in slim type. Also, in this paper, validity of the designed VCM actuator was verified through inquiries on the maximum motion displacement characteristic, displacement response characteristics, hysteresis response characteristics with self made laser displacement sensor-applied characteristics evaluation system in order to evaluate characteristics of the designed VCM actuator.

Specifications of produced VCM actuator is on Table 1. Material of Leaf spring is SUS 301, and yoke is made of Gray cast iron with high permeability. As the result of supplies normal operating voltage 2.75 [V] to the designed VCM actuator and measuring moving part with laser displacement meter, when the maximum rating voltage was supply, the maximum motion displacement value was measured as 509[μm] and it is as in Figure 1. Resistance of VCM actuator is ratio of current consumption to input voltage in the maximum motion displacement, which is 33.1[Ω], the maximum current consumption was 83.2 [μA], and the power consumption at this point was 229 [mW]. In addition, in order to confirm characteristics of durability, VCM actuator was measured of changes after repeating 100,000 times from the minimum motion displacement to the maximum displacement, and to check reliability, hysteresis changes were measured every 5,000 times after the 100,000 times of operation, and as the result, it was confirmed that hysteresis change was insignificant by the maximum value of 15 [μm]. Figure 2 predicts increase of Hysteresis change for 100,000 times of operation using Weibull 6, and it draws a result of changing up to 20 [μm] after 150,000 times.

In this paper, mobile device mountable VCM actuator for auto focus control was made, and in order to analyze operating characteristic of produced VCM actuator, tests of the maximum motion dis-

Development of Laser Beam Steering System Using Three Magnetostrictive Actuators.

J. Jung, Y. Park, K. Im

Mechatronics Engineering, Chungnam National University, Daejeon, South Korea

Over the past 20 years, laser processing systems have found their way in countless industrial applications such as welding, cutting, scribing, engraving, drilling and marking. Laser beam steering system is used to position the laser focus onto the workpiece. Galvanometer is widely used for laser beam steering, but it needs two separate mirrors for two-axis control. Thus, this paper proposes one-mirror laser beam steering system using three magnetostrictive actuators.

Fig. 1 shows a schematic view in two- and three-dimension of the proposed laser beam steering system. The system consists of three magnetostrictive actuators, notch flexure hinge and a mirror. The dimensions of the system are 91 mm in diameter and 112 mm in height. The sizes of mirror are 25.4 mm in diameter and 8 mm in thickness.

The components of the magnetostrictive actuator are magnetostrictive material rod (Terfenol-D) with $\varnothing 10$ mm x L50 mm surrounded by 880 turns of coil, cylinder-type permanent magnet, 7.5 MPa of preloading spring, push rod, flux paths, and housing. The magnetostrictive actuator generated 30 μ m of displacement and about 200 N of force with 2 amperes of current.

A notch flexure hinge is designed to convert linear motion from magnetostrictive actuator into an angular motion. The parameters to be determined are notch radius R , notch thickness t , notch length b , flexure length l . The optimized values for the parameters are $R=2$ mm, $t=1$ mm, $b=10$ mm and $l=24.5$ mm. The notch flexure hinge is made of aluminum. The maximum displacement and angle can be calculated.

$$\theta_{\max} = (4KR/K_t Et) \sigma_{\max} = 2.4 \text{ mrad} \quad (1)$$

$$x_{\max} = 2l\theta_{\max} = 117.6 \mu\text{m} \quad (2)$$

,where stress concentration factor $K_t=1.119$, maximum stress $\sigma_{\max}=54 \times 10^3 \text{ mN/mm}^2$, correction factor $K=0.4485$, Young's modulus of aluminum $E=72 \times 10^6 \text{ mN/mm}^2$ and yield stress of aluminum $\sigma_y=270 \times 10^3 \text{ mN/mm}^2$ [1].

Fig. 2 shows the experimental setup for the measurements of displacement of flexure hinge, marked as X_1 and X_2 . Experimental setup consists of the three magnetostrictive actuators, platform, a current driver for current amplification, power supply and two ADE 4810 Microsense II capacitive sensors with the resolution of 1 nm for the displacement measurement. Magnetostrictive actuator exhibits significant hysteresis over the operating range. The Preisach model is modified and used to compensate hysteresis [2]. Hysteresis-compensated chopping waves are introduced to hinges A and B simultaneously. After 10-seconds, another hysteresis-compensated chopping wave is introduced to hinge C. Using the measured displacements at X_1 and X_2 , an angle can be calculated by using the relationship $\theta=(X_1-X_2)/L$.

Fig. 3 (a) shows the measured displacements and Fig. 3 (b) the calculated angle. The mirror can be rotated up to angle of 1.45 mrad, which is smaller than calculated maximum angle of 2.4 mrad.

A fast magnetization reversal accompanied with a large Barkhausen jump in a magnetic wire is utilized in speed sensor, rotation sensor, and other applications [1,2]. A twisted Vicalloy wire has been the optimum material yielding this phenomenon, which reveals longitudinal anisotropy with coercive force of about 20 Oe in the outer shell (soft layer) and 80 Oe in the inner core (hard layer) [3]. When the magnetization of soft layer is switched parallel/antiparallel to that of hard layer by an external field, positive/negative output voltages are induced in the pickup coil respectively. Previously, the magnetization of the hard layer was not reversed in order to obtain high output voltage owing to switching of the soft layer. The positive/negative outputs were asymmetric in amplitude, which arose from the asymmetric magnetization reversal of parallel /antiparallel switching due to the magnetostatic coupling between the soft/hard layers under the antiparallel alignment and the demagnetizing field under the parallel alignment. These demagnetizing field and magnetostatic coupling increase with shortening the wire length. The output voltage due to the switching of the soft layer was significantly reduced according with the increased magnetostatic coupling between the soft/hard layers in short wires. This characteristic prevents miniaturization of the sensor size. In this paper, magnetization process under an applied magnetic field larger than that in the previous method was studied. In this case, the hard layer was also switched. It was found that the pulse voltage owing to the large Barkhausen jump during magnetization reversal of the soft layer was successfully obtained in short wires (~3 mm).

A twisted Vicalloy (Fe40-Co50-V10) wire of 0.25 mm diameter was used. A pickup coil of 50 turns was located at the center of the wire. The wire length was changed from 1.5 to 9 mm. An alternating magnetic field at 1 Hz was applied to the wire by a solenoid coil. As the hard layer was reversed, the switching of the soft layer was always antiparallel reversal to the hard layer as shown by insertions in Fig. 2. The amplitude of the output voltage during the magnetization reversal of the soft layer was measured as a function of the applied field strength as shown in Fig. 1. The range of the applied field where the output voltage was obtained shifted to higher field strength with shortening the wire length. It was because that the higher field was required in order to switch the hard layer against the larger magnetostatic coupling between the hard and soft layers. Magnetization curves were also measured. The maximum applied field strength for each length of the wires was determined by that for obtaining the maximum output voltage in Fig. 1. All wires exhibited the large Barkhausen jump during the magnetization reversal of the soft layer. It was switched in decreasing the magnetic field for the wires shorter than 4.5 mm, whereas it was reversed in increasing the magnetic field for 6 - 9 mm wires as indicated in Fig. 2. The magnetization of the soft layer in the wires shorter than 4.5 mm was autonomously switched by the large demagnetizing field under the parallel alignment. This successful observation of the induced pulse voltage accompanied with the large Barkhausen jump in the Vicalloy wires as short as 3 mm is significant for sensor applications, especially for implementing as tiny sensor chips.

The effect of ultrasonic resonance on impedance in magnetic rods.

H. Osada, S. Nakamura, H. Hatafuku, S. Chiba, H. Oka
Iwate University, Morioka, Japan

Introduction

When an ultrasonic wave is applied to the end of a magnetic rod, elastic standing waves are generated inside the rod [1]. In this experiment, both ends of the sample are the anti-nodes of the standing wave, and the anti-nodes and nodes are located along a line of the rod. The positions of the anti-nodes and nodes of the standing wave can be observed from the amplitude of the induced electromotive force in the detector coil wound around the rod by means of the inverse effect of magnetostriction [2].

This phenomenon is reversible. That is, the standing wave also can be generated by applying a high frequency voltage using the detector coil as a magnetization coil.

This report describes the change in impedance with the positions of the anti-nodes and nodes of the standing wave in magnetic rods.

Experimental results and Discussion

Figure 1 shows the scheme of the experimental device. The sample (magnetic rod) is supported at both ends by the ultrasonic transducer and a needle is installed in the magnetization coil. A bias magnetostriction is given to the sample by applying a DC magnetic field. The AC signal is inputted to the magnetization coil from the LCR meter, and an elastic standing wave is generated in the sample. Simultaneously, the impedance of the magnetization coil is measured by the LCR meter. In addition, generation of the elastic standing wave is checked by observing the induced electromotive force (EMF) from the ultrasonic transducer bonded to the sample end.

Figure 2 and 3 shows the measurement result for the impedance and the induced electromotive force in the sensing coil on a ferrite rod sample ($\phi 5 \times 100$ mm). The impedance was measured at intervals of 1 mm by setting the ultrasonic transducer side to 0 mm. When the frequency of the magnetization coil is 381.2 kHz, the cycle of the ferrite rod is $n = 7$, and the speed of the ultrasonic wave is $v = 5.5 \times 10^3$ m/s. This figure shows that resistance reaches a local maximum at a position where induced EMF is either at a local maximum or local minimum. Moreover, resistance reaches a local minimum in the position where induced EMF is zero. On the other hand, inductance reaches a local minimum in the position where induced EMF is either at a local maximum or local minimum, and reaches a local maximum in the position where the induced EMF is zero.

When generating an elastic standing wave by means of ultrasonic resonance phenomenon in a magnetic rod, it is thought generally accepted that the magnetic flux inside the magnetic rod is concentrated at the node of the standing wave, and in the part of the anti-node that comes out of or enters the magnetic rod (see Fig. 4). Therefore, when a magnetization coil is in the position of a node, the magnetic flux generated from the coil goes outside in, and out from the position of the adjoining anti-node. On the other hand, when a magnetization coil is in the position of an anti-node, a standing wave is not generated and the magnetic flux runs through the magnetic rod. This difference in the magnetic flux state inside a sample may be the reason for changes in the impedance of the coil because of the position of an anti-node and a node.

Since it is generally accepted that change of such impedance changes also with the stress inside the magnetic rods, it is thought that the state of the inside can be observed in a non-destructive way by measuring the impedance change.

1. Electronic Engineering, Universitat de València, Burjassot, Spain; 2. Microsistemas e Nanotecnologias, INESC, Lisboa, Portugal

1. Introduction

Signal isolator devices are widely used in many electronics systems. Optical isolators and capacitive or inductive couplers are often limited in linearity and frequency performance; they need a notable power consumption and they display a considerable size and usually require hybrid packaging. From the early work of T.M. Herman et al. [1], some approaches have been carried out in the sense of using MR technologies in the basis of novel electrical isolators. TMR structures have been used for digital isolators [2], [3] and spin-valve structures for analog isolators [4]. In this work we study the possibility of using magnetic tunnel junctions (MTJ) based full bridges in order to design analog magnetically coupled isolators. MTJ display some advantages when compared to spin-valve, namely smaller devices and higher magnetoresistance levels (and then higher sensitivity devices).

2. Experiment

The sensing structure was deposited by ion beam sputtering (IBD) onto 3" Si/SiO₂ 1000 Å substrates. The final magnetic tunnel junction configuration was: Al(600Å)/Ta(90Å)/NiFe(70Å)/MnIr(250Å)/CoFe(50Å)/Al₂O₃(12Å)/CoFe(50Å)/NiFe(25Å)/Ta(60Å)/TiW(300Å). The wafer was 90° rotated after the oxidation step in order to ensure a crossed-axis linear configuration. The fabrication of the sensors required six lithographic steps. In the first one, the TMR stacks were patterned by direct laser writing on photoresist followed by soft sputter etching. In the second step, 2×15 μm² junction areas were defined by selective sputter etching. The contact leads [0.150μm Al98.6Si1.0Cu0.4/150Å TiW(N)] were then defined by lift off, for a full Wheatstone bridge configuration. A Al₂O₃ layer was used as isolation barrier. The driven current strips were then deposited and patterned. Pads were opened for external contacts by wet etching in the last lithographic step. Some fabricated sensors were cut into 8.2mm×8.2mm dies and then encapsulated into chip-carriers for testing purposes. The micrograph of the die, as well as the function explanation, is shown in Fig. 1.

3. Results and Discuss

Single resistance test structures were also included on the wafers to perform basic characterizations. A direct current was driven through the integrated current strips, running just above the single MTJ structures. A typical response is displayed in Fig. 1. As observed, the linearity of single MTJ structures is notable even when working alone. In order to characterize the linearity and the sensitivity of the devices, they were fed at a constant direct current of 10mA (through terminals A and B) and the output voltage taken from terminals C and D. A direct current was injected through terminals I_{in}-I_{out} with a hysteresis-detecting loop scheme. Results are shown in Fig. 2. To demonstrate the capability of these devices for acting as analog isolators, different electrical signals were applied through the input terminals, with the help of a signal generator. An illustrative result is shown in Fig. 3, for a triangular example.

Introduction of a Base-Model for Eddy Current Testing of Printed Circuit Boards.

H. Bayani, M. Nishino, S. Yamada, M. Iwahara

Division of Biological Measurement and Applications, Kanazawa University, Kanazawa, Japan

Introduction

Eddy current testing (ECT) is an effective non-destructive method for defect inspection of printed circuit boards[1,2], although two difficulties need to be solved. First, eddy-currents should be induced efficiently in thin and narrow printed circuits. For this purpose a Meander-type excitation coil is used as shown in Fig.1. Second, the pattern of the conductor on PCB is not uniform and is different from conventional ECT, so the output of the ECT probe includes many kind of signals originated from not only defects but also PCB pattern. Consequently, introducing a technique which selects only the defect signal is indispensable for this application. Base-Model method provides the required tools for getting the signals produced by a non-defected PCB directly from its pattern sheet.

Method

1. Disassembling the PCB pattern: It is possible to consider a PCB pattern geometry as an assembling of some basic parts as seen in Fig.2. In this way a complicated pattern could be separated into basic parts.

2. Probe details and physical quantity measurement: A long Meander-type coil is utilized as an excitation coil. To simulate the coil, we use four straight long conductive strips located parallel to each other and carrying equal currents which are in opposite direction in the adjacent strips as seen in Fig.3. The physical quantity which we calculate here is the magnetic flux density due to interaction between the Meander coil and a PCB basic part. Unfortunately there is no analytical solution to such a problem; hence, we use numerical method to solve the problem. Using FEMLAB package, we simulated a Meander coil above a basic part in a 3D mode while quadratic element was considered to obtain an acceptable smoothed result. Since the legs of the coil was supposed to be very long in y-direction and they had periodicity in x-direction, the magnetic field has only tangential component at infinity. Hence, the Dirichlet boundary condition was applied to the problem.

3. Simulation of scanning process and image processing: we put the part in a reference position and ran the package to obtain the magnetic flux density. Then we moved the position of the PCB part one step on the x-direction. Here we considered each step to be 25 μm as in the experiment. After running the program and getting result, the same procedure was repeated for a new position of the PCB part. We repeated the procedure 10 times. For simulating the y-direction scanning process we measure the magnetic flux density on each central line between the strips of the Meander coil which are shown by dashed lines in Fig.3. As the PCB part was moved 10 steps and we also had 3 central lines, we got 30 columns of data. These data were gathered in a matrix to be used for image processing step. To obtain an image of the PCB part, numerical gradient of the aforementioned matrix was taken as an edge detection process. A median filter was also applied to get a clearer image as in Fig.4. One of the most important points in the calculation is related to the width of the sensing area of magnetic sensor which we should take into account. The GMR sensor used in the experiment has a sensing area about 100 μm by 100 μm ; hence, we should consider the effective sensing area as a surface, not as a point, to obtain a more realistic result as close as possible to the experimental result. The wide-area sensing effect causes the final image to be a little blurred in comparison with the result of a point-sensor. On the other hand, calculated results obtained by the Base-Model shows that the resolution of the final image of the basic part is inversely proportional to the scanning step size.

Experimental Results and conclusion

The probe used in the experiment consists of a long Meander coil as an exciter and a SV-GMR sensor to measure the magnetic flux density. The sensor was mounted on the long Meander coil and its sensing axis was set to detect the magnetic flux density, only in the scanning direction. In this research, sinusoidal current of 200 mA at a frequency of 5 MHz was fed to the Meander coil. A lock-in amplifier was used as a data acquisition system for measuring the ECT signal from the sensor. By scanning a small part of a PCB in an experimental situation and applying image processing technique; we get the patterns which can be seen in Fig.3. Subtracting the signal obtained by the method from the signal by the experiment gives the defect signal on a clear background without the complicated PCB conductor pattern. The Base-Model method shows a considerable development in PCB inspection and could be extended to other areas of ECT inspection where the test piece is made of a complicated pattern as well.

Orthogonal Fluxgate with Tube Core Operated in Fundamental Mode.

E. Paperno, E. Wiess, A. Plotkin

Electrical and Computer Engineering, Ben-Gurion University of the Negev, Beer-Sheva, Israel

A new operating mode has been recently suggested for orthogonal fluxgates with amorphous wire core [1]-[4]. In this mode, a dc component is added to the fluxgate ac excitation and their output is detected at the fundamental rather than at the second harmonic. The fundamental-mode operation increases the sensitivity of the orthogonal fluxgates [1], reduces their offset [2], noise [3], and thermal drift [4], thus, making them competitive with state of the art parallel fluxgates [5].

In this work, we suggest applying the fundamental-mode operation to a different type of fluxgates; namely, to orthogonal fluxgates with tube core (see Fig. 1). Excitation current in these fluxgates flows through the toroidal coil wound around the tube core, whereas in the orthogonal fluxgates with amorphous wires, it flows directly through the wire core. Having no excitation current inside the core reduces its heating and, hence, decreases its thermal drift. Employing the toroidal coil also allows decreasing the excitation current, by simply increasing the number of coil turns, while keeping the same intensity of the excitation field.

Our experiments with a tube-core fluxgate (see Fig. 1) have shown a much higher efficiency of the new operating mode as compared with the second-harmonic mode.

To assemble the fluxgate core, we cut a 50x50-mm square from a 22- μ m thick Metglas 2705M amorphous ribbon and coiled it inside a nonconductive pipe, aligning the Metglas magnetic anisotropy circumferentially.

We have found that the excitation with a 6-mA rms ac and 40-mA dc currents provides the maximum signal to noise ratio (SNR) in the fundamental mode. The maximum SNR in the second-harmonic mode was obtained for the same 6-mA ac excitation.

Adding the dc component to the ac excitation has caused a dramatic noise reduction. This effect is especially pronounced at relatively low frequencies (see Fig. 2). One can see from Fig. 2 that the large enough dc bias suppresses the fluxgate noise down to the spectrum analyzer noise floor.

The fluxgate sensitivity increases with frequency in both modes. At a 32-kHz fundamental, it exceeds by a factor of 12.5 the sensitivity at the second-harmonic.

In the fundamental mode, the fluxgate resolution reaches 10 pT/sqrtHz at 1 Hz, which is by an order of magnitude better than in the second-harmonic mode.

The resolution obtained in the fundamental mode exceeds that of a fluxgate with amorphous wire core [3]. We have also observed an about two times lower thermal drift of the fluxgate output compared to [4]. This allows us to conclude that the orthogonal fluxgate with tube core, operated in the fundamental mode, outperforms its counterpart with amorphous wire core.

Fig. 1. Orthogonal fluxgate with tube core.

Fig. 2. Comparison between the output signal voltage spectra obtained for different dc bias currents at the same excitation frequency of 1 kHz. A 40 mA dc bias corresponds to a purely unipolar excitation of the fluxgate core (fundamental mode), and a zero dc bias corresponds to a purely bipolar excitation (second-harmonic mode).

Fig. 3. The fluxgate noise spectra. A 7 nT rms external magnetic field is applied to the fluxgate at a 1 Hz frequency. Note that the noise in the fundamental mode is by an order of magnitude lower than in the second-harmonic mode. (The spectrum line width is 12.5/400 Hz.)

Test of multiturn sensors by a system generating rotating electromagnetic fields with high rotational frequencies.

H. Koebe¹, D. Schmidt¹, M. Scherzinger², K. Bauer², R. M. Mattheis¹

1. Photonic Instrumentation, IPHT, Jena, Germany; 2. Novotechnik, Ostfildern, Germany

Magnetic domain wall based devices have high potential for magnetic storage like high-density memory as proposed by Parkin [1] and Cowburn [2]. For automotive application there is another prospective sensor system, a multiturn sensor [3], which is able to detect and storage the number of turns of a wheel or of other rotating parts of an automobile. Multiturn sensors are necessary for the realization of 'steer-by-wire' or 'drive-by-wire'-concepts. We developed such sensors at the IPHT in cooperation with the Novotechnik factory [4]. A multiturn sensor consists of a GMR-stack which is patterned in a long, narrow helical lane (thickness of 40 nm, width of 150 nm and length of 4 mm). At one end of the helix an enlarged area acting as a domain wall generator is placed, which is responsible for the injection of a domain wall every 180° of rotation whereas the other end of the helix ends in a tapered geometry to avoid domain wall injection from that side of the helix. There is a magnetic window for the functionality of the sensor: the rotating field must be large enough for the reliable injection and transportation of the domain wall and must not exceed the field which could be able to generate a domain wall outside the domain wall generator. The detailed functionality of this sensor was described in [5], see Fig. 1.

For the qualification of such a sensor type with respect to any possible failure, the sensor has to be tested to work correctly for at least 10 millions of revolutions. Every rotation has to be qualified with respect to the correct domain wall motion within the magnetic field window between 10 and 50 mT. We developed a measurement system to realize the qualification process in a short time. The core of this measurement device consists of two serial oscillating circuits containing a stator of an electric motor, a capacitor and a resistor (Fig. 2). There the rotating magnetic field is generated inside the stator of the motor. The capacitors compensate the inductance of the stator and the resistor limits the current and accommodates the impedance of the circuit to the amplifier. The operating and rotational frequency is determined by the resonance frequency of the oscillating circuit. We achieve rotational frequencies of 2 kHz. In addition to that, our system allows changing the rotation direction immediately, because one pair of coils of the motor is placed in an H-bridge consisting of 8 IGBTs (Fig. 2). This enables us to change the direction of the current flow within some microseconds. A microcontroller controls the whole system and is connected to a PC via USB, which collects the data provided by the uC. The voltage of the sensor is read by a high speed ADC. This allows us at least 10 voltage measurements within every half rotation.

In this way we can apply three different test regimes:

- Test of the domain transportation process through the spiral by rotating the magnetic field in the direction of the sense of the spiral and measuring the correct transport to the innermost point of the spiral (determination of the minimum magnetic field).
- Test of the stability of the sensor against high magnetic fields by rotating the field in the reverses sense with respect to the sense of the helix by checking the generation of any domain wall by testing the outer part of the spiral against domain wall movement.
- Full test of the sensor by complete filling and emptying the sensor at least 10 Mio times repeatedly.

The system will be presented and first results of the tests will be discussed with respect to the qualification of the new multiturn sensor for automotive application.

External and internal bias field effect on giant magneto impedance profile.

H. Kim, S. Park, D. Kim, W. Jeung

Division of Materials Science & Engineering, Korea Institute of Science and Technology, Seoul, South Korea

Conventionally, giant magneto impedance (GMI) effect shows symmetric behavior with respect to external magnetic field since its mechanism is based on alternating transverse permeability, whose magnitude is irrelevant to the sign of the external field. For the practical application of GMI devices, many efforts were devoted to induce asymmetric giant magneto impedance (AGMI) effect [1~3]. Representatively, J. G. S. Duque et al. [2] showed that exchange coupling between soft magnetic core and hard magnetic surface, which is formed during field annealing process, can break the symmetry and induce AGMI effect. In addition, N A Buznikov et al, based on the Maxwell and Landau-Lifschitz-Gilbert equation, proposed a theoretical model that can explain the mechanism of exchange biased AGMI effect [3].

However, all these works were based on amorphous soft magnetic wires and, to our best knowledge, no efforts were made to investigate AGMI in crystalline soft magnetic materials. In this work, we examined AGMI profile in electroplated CoFeNi crystalline wires, of which the asymmetry was induced by internal magneto static coupling between soft magnetic CoFeNi wire and mechanically attached AlNiCo hard magnet.

Experimentally, using photolithography process, device patterns having dimensions $150\text{ }\mu\text{m} \times 7500\text{ }\mu\text{m}$ (width \times length) were formed on SUS wafer. CoFeNi micro-wire was electroplated on the patterns with thickness $1\text{ }\mu\text{m}$. For the investigation of internal bias field effect, AlNiCo ($1\text{mm}^2 \times 20\text{ }\mu\text{m}$ (diameter \times thickness)) hard magnet mechanically attached on the CoFeNi micro-wire using epoxy. Distance of the two devices was $200\text{ }\mu\text{m}$ in this experiment. VSM was used for the measurement of magnetic properties of the devices. For the impedance measurement we used a function generator as a ac signal source while rms value of device ac voltage was converted to dc value using AD8361 rf detector chip and then amplified in order to increase signal to noise ratio.

Figure 1. shows the GMI profile of original CoFeNi device which clearly illustrates typical symmetric behavior. Total GMI ratio was measured to be 60 % and impedance maximum field was consistent with anisotropy field, which was confirmed with VSM measurement. When the hard magnet was attached, AlNiCo greatly influenced the GMI profile and induced AGMI effect. (Figure 2) We ascribe this effect to the magneto static coupling between soft magnetic CoFeNi wire and AlCoNi hard magnet. Since the coercive field of AlNiCo is larger than the operating external field range ($-80 \sim +80\text{ Oe}$), internal stray field from hard magnetic layer, which is antiferromagnetically coupled to the soft layer acts as a bias field. Accordingly, it helps the longitudinal magnetization of the device when the external magnetic field is parallel to the magnetization direction of the hard magnet while pins the magnetization of the soft magnetic device on the other. Therefore, the total effective anisotropy of the device becomes asymmetric with respect to the external magnetic field and it is represented as a different maximum value in Figure 2. Furthermore, not only the maximum impedance value but also external field point at maximum impedance is shifted due to asymmetric effective anisotropy. This characteristic of AGMI can be advantageous for the practical application of GMI devices.

Magnetic Gradiometer for Magnetic Moment Measurement using Two Cesium Magnetometer in Earth's Magnetic Field Background.

P. Park¹, Y. Kim¹, W. Kim¹, V. Y. Shifrin²

1. Electromagnetic Metrology Group, Korea Research Institute of Standards and Science(KRIS), Daejeon, South Korea; 2. D. I. Mendeleyev Institute for Metrology (VNIIM), St. Petersburg, Russian Federation

1. Introduction

The atom magnetic resonance (AMR) technique based on the optical pumping polarization of gaseous samples provides very high sensitivity which difficult to realize at application in a variable Earth magnetic field. Usually earth magnetic field variation is thousand times bigger than cesium magnetometer sensitivity.

Used in geophysics optical pumping method employing two or more sensors is a effective way of measuring local magnetic field sources parameters at Earth's magnetic field (EMF) background. It allows fully use the magnetometers sensitivity reducing the least measured field increment to (1 – 2) pT.

With optically pumped gradiometer (OPG), we can precisely measure also effect of the magnetized technical objects in motion that is important for some practical application.

EMF variations are quite uniform at the Earth surface and have the gradient level about 0.01-0.05 nT/km depending on the points of observation. It means the EMF magnetic field variations are the same at distance about 100 m within (1-5) pT difference. For instance, when measuring the magnetic field difference at two points using two ideal (free from the instrumentation noise) identical magnetometers having the base (distance) of 100 m between the sensors, we can get the stable output signal without any variations within 1-5 pT. This instrument is the magnetic gradiometer. When a magnetized object is within the range of the sensor, the balance of two sensors change and the difference is detected.

2. Experimental Apparatus

Fig.1 represents the block-diagram example of Cesium gradiometer application.

In this case Cesium gradiometer measured projection increments of a total magnetic flux density on the basis of 7 m is effected by two cars of different sizes.

Frequencies of the AMR signals from the magnetometers, which are proportional to the magnetic field, were compared at the phase detector. The frequency difference was converted to current and compensated the magnetic field difference inside the Cesium sensor 1 to maintain the equal phases (or frequencies) on the inputs of the phase detector. So the voltage across the standard resistor, which is located in the feedback coil circuit, represents the magnetic field difference between the two sensors.

The car, as an example of the magnetized object, was used for the determination of its space distribution of magnetic field projection on the EMF direction, effective magnetic moment, and the maximum distance for detection.

3. Calculation and Results

The magnetic field distribution of the dipole magnetization of an object is determined by formula 1:

where H-magnetic field strength(A/m), M-magnetic moment(A.m²), R- distance from the object to the point of the measurement(m), x, y - axial and perpendicular coordinates of the measuring point.

Fig.1 shows the result of these measurements. The distance of reliable detection the mini-car Tico and the ordinary size car Excel was 50 m and 68 m respectively.

In order to demonstrate the effectiveness of the scanning of an object, the Cesium AMR gradiometer was designed using the ordinary commercial AMR magnetometers.

Surface flaws detection using AC magnetic field sensing by a thin film inductive micro sensor.

K. Kim¹, Y. Cha¹, J. Kim², J. Sohn², Y. Yoo²

1. Physics, Yeungnam University, Gyeongsan, South Korea; 2. Institute of Nova Magnetics, Nova Magnetics, Incheon, South Korea

The role of electromagnetic-based non-contact and non-destructive evaluation (NDE) of metallic components in engineering industry is increasing [1, 2]. It has been mainly applied for inspection of metal constructions, pipes, parts of plains, and nuclear power plants, etc.. Especially, in order to detect the surface flaws on metallic nonmagnetic and magnetic specimens, the changes of alternative current (AC) magnetic fields detection using the inductive coil sensor with AC source driving to specimens is one of good technique [3]. Induction coil sensors are one of the oldest and most well-known types of magnetic sensors, which transfer function results from fundamental Faraday's law. Today, induction coils are still in common use for their important advantages: simplicity of operation and design, wide frequency bandwidth, shielding from external electromagnetic noise sources and large dynamics. Therefore, we have performed the nondestructive testing (NDT) to detect the metallic surface flaws using the inductive planar micro sensor with a single straight AC driving coil.

The thin film inductive micro sensor was fabricated on AlTiC substrate using photolithography process. The thin film micro sensor has a dimension of $288\ \mu\text{m} \times 360\ \mu\text{m}$ with the thickness of $23\ \mu\text{m}$. The Cu pick-up coil ($2.5\ \mu\text{m} \times 3.5\ \mu\text{m}$) with 40 turns and CoFeNi magnetic film as a magnetic core were deposited by electrolyte process. The size of a magnetic core is $120\ \mu\text{m} \times 145\ \mu\text{m} \times 5\ \mu\text{m}$ with the $0.6\ \mu\text{m}$ -spaced gap between top and bottom layer. Figure 1 shows a schematic draw and real photo images of the thin film sensor. To apply the AC magnetic fields to specimens, a single straight coil with the diameter of $120\ \mu\text{m}$ was used, which was placed in the edge side of the magnetic gap on thin film sensor. The driving Cu coil generates the AC magnetic fields with the frequency range of about 1.6 MHz, which magnetic fields were applied to the artificial cracks on specimen. In order to detect the flaws on surface of the specimens, the thin film sensor probe was moved on surface of specimens with $0.5\ \text{mm} \sim 1\ \text{mm}$ of flying height and $4\ \text{mm/s}$ of scan speed, which was controlled by x, y-axis scanner. The 5 mm-thick nonmagnetic Al and magnetic FeC specimens were prepared with the artificial slit typed flaws. The induced output signals were amplified and filtered by the amplifier. Fig. 2 shows the measuring results with the change of depth and width of slit typed flaws on Al and carbon steel. For an Al specimen, the intensity of the induced voltage was increased with the increment of slit width; on the contrary, the induced voltage was slightly decreased with the increment of slit depth. For a carbon steel specimen, the output signal was slightly decreased with the increase of slit width and depth, respectively. The obtained output signals were good coincidence with the positions of slit flaws. As results, the induced output signal is dominant on nonmagnetic specimen in comparison that on magnetic specimen. It could be related with the relatively different skin depth effects by means of the high permeable magnetic specimens. Fig. 3 shows the real photo images of the coins (Euro, cent) and the obtained image with the $0.1\ \text{mm}$ on one-axis of pixel resolution, which results from the scanning by thin film sensor. Unlike the optical method, the eddy current measurement gives information not only on the actual profile but also on the material. As results, the positions and shapes of surface crack on various metallic specimens were easily detected with high sensitivity. Also, the inductive thin film micro sensor makes it possible to apply in imaging metallic profiles.

Linear magnetoresistance of NiO-spin valve device.

S. Lee¹, Y. Park², D. Hwang³, J. Rhee⁴

1. Oriental Biomedical Engineering, Sangji University, Wonju, South Korea; 2. Oriental Western Biomedical Engineering, Sangji University, Wonju, South Korea; 3. Applied Physics and Electronics, Sangji University, Wonju, South Korea; 4. Physics, Sookmyung Women's University, Seoul, South Korea

The selective magnetic giant magnetoresistance-spin valve (GMR-SV) device includes bio-magnetic materials, such as magnetic beads coated with Streptavidin particles and bio-tin particles whose superior properties can be harnessed to make a sufficiently effective nano-bio device in the future [1]. Presently, the study of the detailed response and behavior of bio-molecules and cells attached to magnetic beads or nano-particles is a very important factor in the biological and medical sciences[2,3].

In this research, with a focus on the nano-magnetic sensitive GMR-SV device for biosensor, we investigated the Property of the linear MR of the fabricated device through experiments.

The sample structure of the GMR-SV device prepared on the substrate of Corning glass (#7059) was made of NiO (300 Å)/NiFe (20 Å)/CoFe (10 Å)/Cu (26 Å)/(CoFe (10 Å)/NiFe (40 Å) multilayers. The direction of the uniaxial anisotropy applied on the deposition of the GMR-SV multilayer was parallel or counter-parallel to the plane of the device with a length of 15 µm. The micro-patterning device with the real region of 2×5 µm² formed the two-probe Al (500 Å)/Cu (200 Å) electrode

The coercivity (H_c), exchange coupling field (H_{ex}), magnetoresistance ratio (MR(%)), and magnetic sensitivity (MS) of the above-mentioned sample and device were measured.

Fig. 1 shows the magnetoresistive (MR) curves for the NiO-SV device, which were measured by the two-probe method. As shown in Fig. 1(a) and 1(b), from the major loop of the MR curve measured in the easy axis. The values of H_{ex} , H_c , MR, and MS values were 120 Oe, 90 Oe, 4.2 %, and 0.3 %/Oe, respectively. Especially, Fig. 1(b) showed that the intensity of interlayer coupling of between the bottom-pinned NiFe/CoFe layer and the top free CoFe/NiFe layer was about 8.0 Oe. It seems like the effect by the difference between the initial direction of magnetization configuration and the direction of the measuring current was larger than that of the demagnetization (shape anisotropy) effect.

To change to the transversal direction corresponding to the width of the biosensor with the longitudinal direction property of the easy axis for the NiO-SV device, we performed vacuum thermal annealing at 200 °C for 1 hr under the permanent magnet of 300 Oe.

Fig. 2 shows the values of H_{ex} , H_c , and MR measured MR curves before and after the annealing process with about 120 Oe and 90 Oe, and 4%. The easy axis minor loop with the H_c of 20 Oe before annealing was changed to the minor loop with the H_c of 2 Oe without the intensity of interlayer coupling and hysteresis property after annealing. From these results, if the final MR curve is in linear proportion to a slightly external magnetic field on the neighboring region of 0 Oe after the annealing process, the enhanced minor MR loop will be used in the detection of magnetic nanoparticles by the biosensor.

Although the magnetic sensitivity was decreased, the reason to perform the linear magnetic property through the thermal annealing process was to obtain the optimum condition to minimize and respond to the coercivity of the GMR-SV device in the surrounding region of 0 Oe by a subtle external magnetic field with increase and decrease. When the GMR-SV device is used as a biosensor with the ultra-micro-magnetic field, the prepared important characteristics include sufficient

magnetic sensitivity and large output amplitudes. Therefore, the direction between the magnetization of pinned layer and the magnetization of free layer should be occurred to be orthogonal to each other. The MR property of the micro-patterned device should be had the linear sensitivity and GMR effect caused by the AMR effect and included the large amplitude.

Introduction

Magnetic rotation angle sensors have high reliability as a non-contact type, and magnetic sensors with AMR films are widely used. But, more sensitive and temperature stable sensors are required for precise angle detections even at elevated temperatures.

Spin-Valve GMR(SV-GMR) films have generally larger MR ratio and smaller temperature coefficient than those of AMR films, then magnetic sensors with SV-GMR films are one of the candidates replacing current magnetic sensors with AMR films.

D.Hammerschmidt et al. has already reported the SV-GMR sensors for automobile applications[1]. But their sensors uses an anti-ferromagnetic(AF) film for the pinned layer, then the temperature characteristics are restricted by the blocking temperature of the AF film. To achieve better temperature characteristics, SV-GMR films without any AF films are required.

The present paper investigated temperature characteristics of magnetic rotation angle sensors with SV-GMR films prepared using synthetic anti-ferromagnetic layer(SyAF) as the pinned layer without any AF films.

Experiment

SV-GMR films were deposited on Si wafer substrates by DC magnetron sputtering technique. The pinned layer structure is only CoFe/Ru/CoFe without any AF films. The typical composition of the SV-GMR films is Substrate/CoFe(2.1nm)/Ru(0.4nm)/CoFe(2.0nm)/Cu(2.2nm)/CoFe(1.0nm)/NiFe(2.0nm)/Capping layer. The pinned direction of these films is parallel to the direction of the magnetic field applied during sputtering the first CoFe layer. The rotation angle sensors with a pair of full-bridge were prepared by a conventional photolithograph process to detect angles from 0 to 360 degree. The directions of the pinned layers were set rectangular between full-bridges and set anti-parallel in the half bridges. This setting promises better temperature characteristics. The rotation angle measurements were carried out in the 2-axis Helmholtz coil with 24kA/m magnetic field, applying 5V DC in the bridges.

Results

The typical MR ratio of the SV-GMR films was 10% and the temperature dependence of MR ratio was flat up to 573K, much better than that of SV-GMR using PtMn AF film as the pinned layer.

The output voltage(peak to peak) of the sensors was around 450mV and the temperature coefficient of the output was $-0.25\%/K$ up to 453K. The temperature drift of the offset voltage of the full bridges was $0.01mV/K$. Measured angle errors at room temperature were less than ± 0.5 degree after compensating both offset voltages and output amplitudes. Up to 453K, the measured angle errors were kept within ± 0.5 degree after the compensation at each temperature. The results are plotted in Figures 1 and 2 including hysteresis angle errors.

Magnetic field intensity dependence upon the measured angle errors was also evaluated. The angle error at 4.8kA/m was ± 1.5 degree, but the error was reduced as the magnetic field intensities increase. The error was less than ± 0.5 degree at 16kA/m and more. The results are plotted in Fig.3.

Then we conclude that magnetic rotation angle sensors using SV-GMR film of SyAF pinned layer without any AF films possess both excellent temperature characteristics and high sensitivities.

Nitride based (AlGaIn/GaN) micro-Hall sensor.

Magnetization measurements in micro and nano sized materials can be performed using micro Hall sensors. A real improvement is to place a magnetic material on top of a semiconductor heterostructure where a two dimensional electron gas (2DEG) is generated at few nanometers from surface. GaAs-based systems have been extensively used in the past because of their long electron mean free path [1,2] and high RH constant. However, GaAs heterostructures are very sensitive to temperature and that produces stability problems during measurements, reducing their application range. Additionally there are concerns about its toxicity when used for biological applications.

In this work we present magnetization measurements in a micrometric size ferromagnetic thin film (Fig. 1) using a triple Hall sensor based on a 2DEG (Al,Ga)N/GaN heterostructure grown by plasma-assisted MBE. Figure 2 shows the charge distribution versus depth, in the AlGaIn/GaN heterostructure, calculated from capacity-voltage measurement, while the inset shows the temperature dependence of the charge density and carrier mobility obtained from Hall effect measurements. These results confirm the presence of a high mobility channel (2DEG) at the AlN/GaN interface. The main advantages of this nitride-based Hall sensor are its high temperature stability [3,4] and its truly compatibility with any biological application.

Using lift off procedures a 100 nm thick Permalloy (Ni80Fe20) bar was grown by Ar sputtering. The bar size was the adequate to produce a strong dispersion magnetic field in two of the sensors, in such a way that these sensors are sensitive to a magnetic field applied perpendicular to the sample and to the dispersion field produced by the magnetic material (positive in one sensor and negative in the other). The central Hall sensor is only sensitive to the magnetic field applied perpendicular to the sample. When a magnetic field is applied parallel to the sample plane, the Hall sensor signal is mainly due to the dispersion field that is directly related with the sample magnetization. Figure 4 shows an hysteresis loop measured with an in-plane magnetic field applied along the magnetic bar. This hysteresis loop shows an unexpected high coercive value and a shape similar to the one observed in thicker samples [5]. This effect is possibly due to an interaction between the heterostructure semiconductor surface and the magnetic material and it should be avoided to improve the sensor performance.

Enhancement of sensitivity in a magnetic sensor by combining planar Hall resistance and giant Magnetoresistance.

H. Tran Quang¹, S. Oh¹, D. Nguyen Huu², C. Kim¹

1. Department of Materials Science and Engineering, Chungnam National University, Daejeon, South Korea; 2. College of Technology, Vietnam National University, Hanoi, Viet Nam

Introduction:

Sensor designs to combine magnetoresistance and planar Hall resistance (PHR) by using bridge type and different contact arrangements were reported. However, the review of the literature reveals that there is no available report so far on the role of sensitivity of the magnetic sensor with a tilt angle of the cross junction bars. We report here a new kind of magnetic sensor by combining giant magnetoresistance (GMR) and PHR in order to enhance the sensitivity of magnetic sensor while taking into account the contribution of a tilt angle of cross junction using spin-valve structure. In order to understand the experimental data, a simple calculation based on Stoner-Wohlfarth model is introduced.

The first order approximation of Stoner-Wohlfarth energy of rotation process of magnetization in spin-valve structure was reported [1]. The energy term of the Stoner-Wohlfarth model can be rewritten as follow:

$$E = K_u t \sin^2 \theta - M_s t H \cos(\alpha - \theta) - J \cos(\beta - \theta) \quad (1)$$

here, the t , θ , K_u , M_s are the thickness, the angle between magnetization and easy axis direction, the effective anisotropy constant, and the saturation magnetization of the free layer, respectively. J is the interlayer coupling, α is the measurement angle between external magnetic field and easy axis, and the β is the angle between the exchange bias field direction and the easy axis of free layer.

The four terminal Hall bars with a tilt angle ζ is shown in Fig. 1. When M makes an angle θ with J , under transverse magnetic field, the total resistance of junction with the tilt angle ζ can be approximately described as:

$$R = R_{PHR} + R_d + \Delta R_{GMR} \quad (2)$$

where $R_{PHR} = (R_{\parallel} - R_{\perp}) \sin \theta \cos \theta$ is the planar Hall resistance component, $R_d = R_{\perp} \sin \zeta$ is the drift resistance [2], $\Delta R_{GMR} = R_0(1 - \cos \theta)$ is the GMR component.

The output voltage profiles with different values of tilt angles can be calculated theoretically by combining Eq. (1) and Eq. (2) under the condition that the energy E is minimal.

Experiments and results:

Spin-valve structures of Ta(5)/NiFe(6)/Cu(3)/NiFe(3)/IrMn(15)/Ta(5) (nm) were fabricated using a four-gun dc magnetron sputtering system and were patterned into four terminal Hall bars (Fig. 1). The variation of angle ζ is set to 0, 4, 8, 10, 30, 45 degrees. The exchange bias field direction and the current direction were aligned parallel to the long terminals a and b . Output voltages were measured from the short terminals c and d at room temperature under the application of external magnetic fields ranging from -45 Oe to 45 Oe along the direction of the film plane.

The voltage profiles of cross junctions with various tilt angles showing in Fig. 2 were measured by a Keithley 2182A Nanovoltmeter, whose sensitivity is 10 nV.

Discussion:

The result of separation PHR and GMR components of junction with $\zeta = 10^\circ$ is showed in Fig. 3. The increase of resistance in the positive magnetic direction is larger when compare with the decrease in negative magnetic field range. The increase and decrease in resistance are due to the contribution from GMR component and PHR component. This results in increase the sensitivity of magnetic sensor.

The sensitivity of various tilt angles of sensor elements is estimated and is given in table 1.

In conclusion, the magnetic sensors with various tilt angles utilize better sensitivity in compared with PHR or GMR sensor. A simple model is introduced to understand the role of contribution of GMR and PHR to the total output voltage.

The sensor for nano-scale magnetics has potential applications in fundamental study of biological interactions as well as utilities in bio-analysis and biomedical applications. Micro-magnetic sensors proposed thus far are based on magnetoresistive technologies such as GMR and TMR which suffer from nonlinear responses and saturation at low field. Another kind of sensor is Hall device which has difficulty in the integration of sensor array and requires a bulky system caused by using AC magnetic field. To overcome the drawbacks of these conventional devices, we have fabricated a magnetic sensor made of InAs 2DEG and its signal is detected by measuring longitudinal resistance.

The structure of our device is displayed in a scanning electron microscope image as shown in Fig. 1(a). An InAs 2DEG mesa, with a current channel from I+ to I- and two voltage probes denoted as B and C was patterned by electron beam lithography. The current channel is $2.8\ \mu\text{m}$ wide and the voltage probes are separated about $2.8\ \mu\text{m}$ from center to center. A single magnetic particle was manipulated on top of the InAs 2DEG mesa. The InAs 2DEG resides $35.5\ \text{nm}$ below the surface. The mobility and the carrier density of InAs 2DEG (2-dimensional electron gas) is $7.86\ \text{m}^2/\text{Vsec}$ and $2.0 \times 10^{16}\ \text{m}^{-2}$ respectively, at $T = 2\ \text{K}$ and $2.0\ \text{m}^2/\text{Vsec}$ and $2.1 \times 10^{16}\ \text{m}^{-2}$ at room temperature (RT). Since the mean free path at $2\ \text{K}$ is $1.85\ \mu\text{m}$, the transport mechanism at $2\ \text{K}$ can be treated as ballistic motion. Fig. 1(a) show in which the widths of the current channel and the voltage probe are $2.8\ \mu\text{m}$, and the size of magnetic particle is $2.8\ \mu\text{m}$.

In a conventional Hall sensor magnetic particles are located on the center of a cross-shaped Hall sensor. But our device can obtain a signal when the magnetic particle place in the middle of two neighboring voltage probes. Resistance was measured using a DC measurement and a standard lock-in technique with low-frequency ($98\ \text{Hz}$) ac of $10\ \mu\text{A}$. The signals were measured by passing a current through terminal [I+] and [I-] while the voltage was measured between a pair of probes [B] and [C]. When an external magnetic field (B_{ext}) is applied, a magnetic particle is located between voltage probes and the stray field generated by the magnetic particle leads to the variation of resistance (see RBC in Fig1.(b)).

Further miniaturization of our device to submicron dimensions will lead to a high performance biological sensor for detection of nanometer-size particles.

Fabrication and Characterization of Silicon Micro Hall Sensors for Scanning Hall Probe Microscopy (SHPM) Using Multiple Feedback Techniques.

R. Akram, M. Dede, A. Oral

Department of Physics, Bilkent University, 06800, Ankara, Turkey

In this report we present the fabrication and characterization of Silicon on Insulator (SOI) micro hall sensors for scanning hall probe microscopy (SHPM) using different feedback configurations. Compatibility of fabrication process with standard CMOS fabrication process and controllability on the characteristics parameters of Silicon makes them a more advantageous, for hall probe applications, over other compound semiconductors (AlGaAs/GaAs, InSb and AlGaN/GaN) which are mainly based on 2DEG heterostructures or thin films.

Silicon micro hall probes were produced using optical lithography and reactive ion etching of SOI wafers. The active area of the hall probes were $\sim 1 \times 1 \mu\text{m}^2$ with the thickness ranging from 250nm to 500nm, the picture of the Hall probe is shown in Figure 1. These probes have been characterized based on their electric (V_H vs. I_H), magnetic (R_H vs. I_H), noise and temperature characteristics. Figure 2 shows a dependency of Hall voltage, V_H , and Hall coefficient, R_H , on the Hall current. A typical value of Hall coefficient, carrier concentration and series resistance of the Hall sensors were $0.95 \text{ m}\Omega/\text{G}$, $2.2 \times 10^{19} \text{ cm}^{-2}$ and $22 \text{ k}\Omega$ at room temperature with Hall current of $500 \mu\text{A}$.

Application of Silicon Hall sensors in SHPM have been investigated using conventional scanning tunneling microscopy (STM) feedback and a novel Quartz Tuning Fork (QTF) in atomic force-guided scanning (AFM) Hall probe microscopy (SHPM). Simultaneous scans of magnetic and topographic data at various pressures (from atmospheric pressure to high vacuum) at temperatures ranging from 77K to 300K will also be presented for different samples to illustrate the capability of Silicon Hall sensors in variable temperature-SHPM.

Electrical (V_H vs. I_H) and Magnetic (R_H vs. I_H) Characteristics of Si $1 \mu\text{m} \times 1 \mu\text{m}$ Hall probe.

Magneto-impedance property in a micromachined magnetic LC-sensor device.

A. Le¹, S. Yu¹, H. Lee², V. Manuel³

1. BK 21 Physics Program and Department of Physics, Chungbuk National University, Cheongju 361-763, South Korea; 2. Department of Physics Education, Kongju National University, Kongju 314-701, South Korea; 3. De Instituto de Ciencia de Materiales de Madrid, CSIC, Campus de Cantoblanco, 28049 Madrid, Spain

In recent years, an increasing interest in the development of miniaturized smart structures and systems, particularly on micro and nano electromechanical systems (MEMS and NEMS) and integrated sensor systems have evolved a new page in the science and engineering field. In order to approach this, we have proposed and developed a novel micromagnetic LC-sensor device with soft ferromagnetic microwires as sensing element, giving an emphasis on the use of resonance effect from LC-components to improve the sensitivity of sensor. A micro LC-sensor device consists of a solenoidal microinductor with a bundle of soft magnetic microwires as a core and a capacitor connected in parallel to the microinductor. The solenoidal microinductors were fabricated with varying dimensions of 500 – 1000 μm in length, 200 μm in width, 75 μm in height, and with 10 – 20 turns by adapting the MEMS techniques including the spin coating of photoresist, ultraviolet lithography (UV-LIGA) process, and metal electroplating. To form a LC-electric circuit, the varying external capacitors from 1 - 100 pF were connected in parallel to the microinductors. Magneto-impedance (MI) measurements were conducted using an rf impedance analyzer (HP4191A) in a wide range of frequencies from 1 MHz – 1000 MHz and a varying dc magnetic field within 300 Oe. Because the permeability of soft magnetic microwires core varies rapidly as the external magnetic field changes causing a large variation in the inductance of microinductors and, therefore the impedance of the micro LC-sensor device. It is important to note that the impedance variation of a micro LC-sensor device can be significantly improved by working at resonant conditions in a LC-electric circuit. In our present case, the magnitude of impedance changes was extremely enhanced by adjusting the measuring frequencies at near the resonance point. This originates from both the strong change in permeability of the microwires caused by external magnetic field and the LC resonance effect of the sensing elements. In the present work, the largest MI ratio up to 500% with very sharp peak was obtained at a frequency of 263.4 MHz for a micro LC-device with an external capacitor value of 10 pF as shown in Fig. 1. The calculated maximum field sensitivity of the micro LC-device reached an extremely high value of 420 %/Oe. This value is of practical importance in the development of highly sensitive micromagnetic sensors that can operate at high-frequency region. It is also noteworthy that the resonant frequency and the field sensitivity of LC-sensor devices were considerably altered with change in external capacitor values. Our experimental results have been demonstrated that the resonance frequency of micro LC-sensor devices decreases from 569 MHz to 72 MHz when the external capacitor value increases from 1 pF to 100 pF as shown in Fig. 2. This indicates that by changing values of external capacitor, the operating frequency of the sensor device can be precisely tuned for desirable purposes. It is worth to noting that the field sensitivity of micro LC-sensor devices also alters as the external capacitors changes (see Fig. 2). Consequently, an appropriate selection of the external capacitor for making a LC-resonant circuit is necessary for the design and fabrication of practical micromagnetic sensors with desired sensitivity and operating frequency.

To clarify the influence of core material, we examined the effect of number of microwire cores on the sensing characteristics of device. Here, the dimensions of microinductor and the external capacitor were fixed, whereas the number of microwires (n) was varied from 1 - 5. The experimental

results showed that the sensitivity of device increased with increasing the number of microwire cores in the sensing element. As one can see clearly from inset of Fig. 1 the calculated field sensitivity increases from 40 %/Oe to 92 %/Oe as the number of sensing microwire cores increases from 1 to 5. In our present case, the increase in sensitivity is likely due to the dynamic magnetic interaction between the ferromagnetic microwire cores in the sensing element under the influence of high-frequency excitation current. Finally, it is interesting to mention that the feature of a LC-sensor circuit can be ideally used for developing highly sensitive microsensor devices or for improving the sensitivities of magnetic sensors. This also opens up a new opportunity to design smart microsensor structures containing short magnetic microwires for a variety of engineering and technological applications.

Half-metallic magnetic materials and hybrid spintronic Structures.

Y. Xu

Department of Electronics, The University of York, York, United Kingdom

The second generation spintronic devices, integrating magnetic materials with semiconductor devices, will not just improve the existing capabilities of electronic devices, but will have new functionalities enabling future computers to run faster, but consume less power, which is expected to have a impact comparable to the development of transistors 50 years ago. There are currently two classes of material systems exploited for use in the second generation spintronics a) Dilute magnetic semiconductors, b) Hybrid magnetic/semiconductor spintronic structures. The dilute magnetic semiconductors might offer opportunities of easy integration with conventional semiconductor devices, but the challenges are to increase their Curie temperatures and their magnetization apart from understanding the origin of the ferromagnetism in this system. The hybrid spintronic structures have the advantages of high Curie temperatures, well controlled magnetic properties, and easy integration with current magnetic technologies; in particular, by integrating half-metallic magnetic materials as high efficient spin sources [1]. In this invited presentation, we will report our studies of three types of promising hybrid spintronics materials and devices based ferromagnetic metals and half-metallic oxides and Heusler alloys.

The hybrid spintronic structures integrating half-metallic magnetic oxides and Heusler alloys are exciting for the second generation spintronics as a 100% spin polarisation is expected for high efficient spin injection. By using post-growth annealing, we have synthesized epitaxial magnetic oxide Fe₃O₄ on GaAs(100) and the unit cell of the Fe₃O₄ was found to be rotated by 45 degree to match of GaAs [2]. The formation of the ferrimagnetic Fe₃O₄ rather than Fe₂O₃ or other ion oxides has been further confirmed by XPS and XMCD measurements. The ultrathin films have a uniaxial anisotropy possibly related to the strain due to the lattice mismatch. The system has a moderate Schottky barrier of around 0.3-0.4eV, which is favorable for spin-injection [3]. Furthermore, the films were found to have a bulk like moment down to 3-4 nm indicating a sharp interface. We are currently developing high efficient spin-LED with this half metallic Fe₃O₄.

In the Heusler alloy systems, such as Co₂MnGa on GaAs, we found that the magnetic moment was reduced by more than 50% for the thickness down to 5nm. Using the elementary specific XMCD technique, we have further found that the reduced spin moments come from the Mn rather than the Co, but the orbital moments are not reduced [4]. Our studies suggested that more work is needed to improve the growth of Heusler alloy/semiconductor hybrid spintronics structures to have a clean interface in order to make use of this encouraging material system.

In the ferromagnetic metal based system, while our previous XMCD study demonstrated that the Fe atoms on GaAs (100) are ferromagnetic down to submonolayer at room temperatures [5], our studies of Co and Ni show that the Co atoms are similar to that of Fe with bulk-like spin moments down to submonolayer, but the Ni atoms lost their magnetic moments on the GaAs surface [6]. This demonstrated clearly that the magnetism of ferromagnetic metal/semiconductor interface depends strongly on the materials used.

We have fabricated a vertical hybrid ferromagnetic/III-V semiconductor/ferromagnetic spintronic devices namely, Co/GaAs (50nm, n-type)/Al_{0.3}Ga_{0.3}As (200nm, n-type)/ FeNi and studied their magneto transport properties [7]. The I-V characteristics revealed Schottky/tunneling type behavior and are dependent on external fields beyond a bias voltage of 5 V indicating that a high barrier related to interface oxide layer has been introduced in the device. The MR shows a strong dependence both on bias current and applied field. A 12% change in MR has been observed at room tem-

perature, which is far larger than that of conventional AMR effect indicating strong spin injection and detection occurred in this device. The device also exhibited interesting field dependent MR behaviour which could be compared to field effect transistor characteristics. We are currently working on full epitaxial Fe/GaAs/Fe vertical devices with magnetic interfaces, and this structure might offer an opportunity to have a large room temperature electric spin injection and detection essential for the operation of the second generation spintronic devices.

Searching for quaternary Heusler alloys with half-metallicity.

X. Dai, G. Liu, G. Fecher, C. Felser

Institut für Anorganische und Analytische Chemie, Johannes Gutenberg-Universität Mainz, Mainz, Germany

In this work, we will focus on the searching for the quaternary half-metallic Heusler alloys by the first-principle calculations. As an example, the Heusler-type CoFeMnSi with different superstructures have been investigated. A semi-experiential rule to develop quaternary half-metallic Heusler alloys will be also presented. As a Heusler-type compound with four different elements, there exist three non-equivalent highly-ordered alignments of atoms as shown in Fig 1.

We optimize the lattice constants for CoFeMnSi compounds with different superstructures and calculated their electronic structures with the optimized lattice constants. The calculated results were shown in Fig. 2. For the type I structure, the Fermi level verily lies in an energy gap of the spin-down states. For the type II structure, the electronic structure is similar to that of type I. However, the Fermi level lies in a deep valley in the spin-down states but not a real gap. As to type III arrangement, a spin-polarization behavior of the general ferromagnets was observed at the Fermi level. These results indicate that the CoFeMnSi compound with type I or type II structure is half-metallic ferromagnet while the type III anti-sites will destroy the half-metallicity. Fortunately, based on an experiential rule discussed in ref.1, we can predict that the CoFeMnSi composition will firstly favor the type I superstructure, secondly type II, which is also confirmed by our calculations of total energy.

As discussed in our previous works, the half-metallic band gap in Heusler alloys results from two mechanisms: covalent band gap and d-d band gap. The former roots in the covalent hybridization between the nearest atoms. The hybridization leads to the formation of bonding and antibonding bands, which further generates a band gap between the bonding and antibonding bands. The origin of d-d band gap has been elucidated in Ref.2. It was shown that the gap arises between the occupied t_{2g} and the unoccupied e_g states which are exclusively localized in space at the A and C sites since the d orbitals of the atoms at B sites do not transform with the u representations [2]. The final width of energy gap for a compound will be determined by the smaller one of the covalent band gap and the d-d band gap.

Based on the analysis of the electronic structures of the CoFeMnSi with different superstructures, one can see the high valence transition metal atom (like Co, Ni elements) is not proper one to occupy the B sites as the contributor of the covalent band gap. As in CoFeMnSi compound, when the Co atom is at the B site, its spin-down states have to strongly hybridize with that of Fe since they have many spin-down states distribute in the similar energy area, which makes the d electrons delocalize, so the bonding and antibonding states difficult to form. At the same time, the d-d band gap was also difficult to form due to the absence of the spin-down states with similar energies in Mn and Fe atoms. However, when the Mn atom is at B site, the Co and Fe atoms have quite many spin-down states at the similar energy area, which is easy to generate a t_{2g}-e_g band gap. As shown in Ref. [3], the covalent hybridization is easy to occur between the lower-energy d states of the high-valent transition metal Co atom and the higher-energy d states of the lower-valent transition metal Mn atoms, which lead to the formation of band gap between the bonding and antibonding bands. The bonding hybrids are localized mainly at the high-valent transition metal atom site, while the unoccupied antibonding states are localized mainly at the lower valent transition metal site.

In summary, a good field to develop new half-metallic materials is the quaternary Heusler alloys. The preferred route is to combine the compounds that have been already grown in the Heusler L21

lattice, which is advantageous to the realistic synthesis. In the quaternary compounds, the atomic positions must be considered as an important aspect.

The origin of the Anomalous Hall effect (AHE), present in magnetic materials, has been a controversial issue for decades, where theories based on intrinsic [1] or extrinsic contributions [2,3] tried to explain this effect. A recent theory [4] based on multi-band ferromagnetic metals with dilute impurities seems to have solved this complex scenario where three regimes can be distinguished as a function of the longitudinal conductivity. In the dirty regime ($\sigma_{xx} < 104 \Omega^{-1} \text{cm}^{-1}$), as it is the case of magnetite, a relationship $\sigma_H \propto \sigma_{xx}^{1.6}$ is predicted, caused by the damping of the intrinsic contribution.

We report a systematic study of the AHE in epitaxial Fe₃O₄ thin films grown on MgO (001) with in a wide range of thicknesses (5-150nm) and in the temperature range from 300K down to 60K. Fe₃O₄ thin films were grown on MgO (001) substrates by pulsed laser deposition. Structural and magnetic characterization indicate a 001-oriented epitaxial growth as well as a high cristallinity of the films. For electrical transport measurements a two-step lithography process was carried out. The typical electrode for the flow of the current was 300 μm wide and additional pads were patterned for the measurements of the voltage drop [5]. The values for the resistivity at room temperature increase monotonically for decreasing film thickness (from 5.46 m Ωcm for the 150 nm film to 121.4 m Ωcm for the 5 nm film) This result is mainly associated with the increase of anti-phase boundaries (APB) density [6].

We have measured the AHE for the different thickness in the temperature range from 300K down to 60K and with fields up to 11kOe (see Fig 1 and 2). In this range of magnetic fields, the contribution of the AHE dominates completely the Hall effect. The values for ρ_H increase in modulus monotonously when the temperature diminishes, presenting a huge enhancement as the temperature the Verwey transition is approached. This effect is related with changes in the electronic structure and the spin-orbit coupling that occurs at the transition [7]. In figure 3 we show the absolute value of the Hall conductivity at maximum field as a function of the longitudinal conductivity for all the samples measured. In spite of the different thicknesses and measurement temperature, the relationship $\sigma_H \propto \sigma_{xx}^{1.6}$ (dashed line) is followed in all cases, as it is expected in the dirty range of conductivities. Together with our results, other measurements found in the literature for the AHE in magnetite have also been plotted. These data approximately match with ours, revealing the same physical origin in all cases. All these facts support the belief that the relationship $\sigma_H \propto \sigma_{xx}^{1.6}$ is universal for this low-conductivity regime.

One of the most promising spintronic materials is the half-metallic oxides as they have high spin polarisation at the Fermi level making them useful in the application of magnetoresistive devices. Magnetite (Fe₃O₄) is a robust ferrimagnetic material with a Curie temperature of 858 K [1]. Theoretical band calculations predict a half-metallic character with only minority spin (spin down) electrons present at the Fermi level [2,3]. In order to introduce the half-metallic materials in the spintronic technologies, one needs to integrate them with the semiconductors of conventional electronics.

Recently, we succeeded in growing monocrystalline ultrathin films of Fe₃O₄ on GaAs substrate by molecular beam epitaxy (MBE) using post-growth annealing of the Fe film in a partial pressure of oxygen [4]. The results suggested that the film structures and properties might depend on the grow conditions. In the present work, we have carried out a detailed RHEED, XAS, XMCD, XPS and AGFM study of the effect of the O₂ pressure on the sample's structures and magnetic properties, and the optimised pressure was found to be around 4-8x10⁻⁴mbar.

Seven samples have been prepared using MBE growth facilities at the University of York. They consisted of a 6nm thin Fe films on GaAs substrates transformed to magnetite by in-situ exposure to a variety of O₂ pressure ranging from 1.25 x 10⁻⁵ mbar to 8 x 10⁻⁴ mbar at a fixed controlled temperature of 180oC for 10 minutes. The temperature used in this study is lower than that of 230 oC reported previously [4]. This is to reduce possible intermixing at the interface.

The in-situ RHEED patterns confirmed the growth of Fe₃O₄ of all seven samples. However, as RHEED is surface sensitive and cannot differentiate between Fe₃O₄ and maghemite γ -Fe₂O₃, we have further studied these samples using XPS technique. The XPS measurements showed widened and shake-up satellite free spectra confirming the growth of Fe₃O₄ rather than γ -Fe₂O₃. Interestingly, the samples oxidised at low Oxygen pressures have shown a small shoulder on the Fe 2p_{3/2} spectra at a binding energy of about 707 eV, which could be attributed to a certain percentage of unoxidised metallic Fe beneath the surface magnetite layer [5].

The XAS and XMCD measurement have been carried out at the station 1.1 on the SRS in Daresbury Labs. Figure 1 shows the XMCD spectra of the 6nm Fe₃O₄ prepared at different oxygen pressures and normalized to the FeOH₃⁺ Peak. The XAS and XMCD results have further confirmed that, with increasing the oxygen pressure up to 8x10⁻⁴ mbar, better quality magnetite samples with a reduced contribution from any other phases can be obtained. The contribution of metallic Fe has been subtracted and the spin and orbital magnetic moment have been calculated from the Sum rules. The detailed results will be presented at the conference.

The AGFM measurements showed a change on the coercive fields from couple of Oersted up to 75 Oersted for the different samples which could be used to tailor the magnetic properties of the prepared samples by using different oxygen pressure. Moreover the samples prepared at the lower O₂ pressure showed a double switching, which could be attributed to unoxidised metallic Fe saturate independently from the rest of the magnetite thin film.

Recently, ruthenates have been widely investigated for their peculiar properties, such as the unconventional superconductivity in Sr_2RuO_4 and the ferromagnetic (FM) metallic behavior in SrRuO_3 [1,2]. CaRuO_3 , similar to SrRuO_3 , has an orthorhombically distorted GdFeO_3 -type structure and shows a metallic conductivity. On the other hand, the magnetic properties are significantly different from those of SrRuO_3 [2]. The detailed magnetic structure of CaRuO_3 is still unclear. The main debate focuses on whether there exists antiferromagnetic and/or FM spin interaction in CaRuO_3 . The ground state of CaRuO_3 is sensitive to the impurity doping. The recent works exhibit that a disorder is doped into CaRuO_3 by the partial substitution with foreign elemental ions such as Cr^{3+} , Sn^{4+} , Mn^{4+} , Ti^{4+} and Fe^{3+} [2]. Thus, CaRuO_3 is believed to be a compound that is on the verge of magnetic ordering. Even though many transition-metal ions were introduced into CaRuO_3 up to now, few works have been devoted to the doping effect of Mo ions in CaRuO_3 . In this work, the magnetic and the transport properties of polycrystalline $\text{CaRu}_{1-x}\text{Mo}_x\text{O}_3$ have been studied. Polycrystalline $\text{CaRu}_{1-x}\text{Mo}_x\text{O}_3$ ($x = 0$ and 0.02) perovskite samples were synthesized by the conventional solid-state reaction. The XRD spectra show that both kinds of samples are in a single phase of the Pbnm orthorhombic structure (not shown here). The resistivity measurements were performed by the conventional four-probe method in a temperature regime between 10 and 300 K. The magnetic properties were measured by using a superconducting quantum interference device magnetometer.

Figure 1 presents the temperature dependence of magnetization $M(T)$ investigated in zero field cooling (ZFC) and field cooling (FC) modes with an applied field of 1000 Oe. As shown in Fig. 1, in the low temperature region, the magnetization of CaRuO_3 shows a remarkable increase with decreasing temperature, which indicates the formation of the FM order. The ZFC curve and the FC curves are divided below 12.7 K, which is a character of the spin-glass state. This implies the existence of the short-range antiferromagnetic spin interaction, which makes the spin order frozen at low temperatures. For the $\text{CaRu}_{0.98}\text{Mo}_{0.02}\text{O}_3$ sample, both ZFC and FC curves are nearly superposed on those of CaRuO_3 , respectively. It seems that the Mo ionic doping hardly changes the magnetic properties of this system. According to the $M(H)$ curves (Fig. 2), the FM interaction begins to take place above 15 K while the AFM one exists only below 12.7 K (seen in Fig. 1). The doping of Mo ions hardly affects the AFM interaction but enhances the FM one. The temperature-dependent resistivity, $\rho(T)$, curves of CaRuO_3 show a metallic conductivity in the high temperature region and an insulating state at low temperatures, but the value of resistivity is small in the whole temperature region (Fig. 3). $\text{CaRu}_{0.98}\text{Mo}_{0.02}\text{O}_3$ reveals an insulating behavior in the investigated temperature range. The doping of Mo ions enhances the insulating properties. According to variable-range hopping model, the electrons become more localized with the doping of Mo ions, which results in the larger resistivity of $\text{CaRu}_{0.98}\text{Mo}_{0.02}\text{O}_3$ with respect to CaRuO_3 .

Ferromagnetic/superconducting oxide interfaces have received a great deal of attention due to their intriguing physical properties [1-11], such as the giant magnetoresistance (GMR) found in $\text{YBa}_2\text{Cu}_3\text{O}_{7-x}/\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ (YBCO/LCMO) superlattices [7,10] and a strong interplay between ferromagnetism and superconductivity [3] which suggests of a long range proximity effect [4]. Since these systems have significant potential towards applications of spin injection from a ferromagnet into a superconducting electrode, such heterostructures where a high T_c superconductor (a cuprate) and a manganite exhibiting colossal magnetoresistance are combined have attracted significant attention in the past few years [1-11]. Reduced dimensionality, novel interactions and/or the aforementioned proximity effects across the interfaces can give rise to unexpected physical behaviors. The possibility of interface charge transfer drastically affecting the interface properties has been recently examined [9,11,12]. But harnessing these phenomena relies on a detailed understanding of the structure, chemistry and physical properties of these interfaces with atomic resolution, in real space.

For this aim, aberration corrected scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS) combined with first principles calculations have proven to be very effective to improve our understanding of such systems [13]. STEM-EELS is a most powerful tool to study the structure, chemistry and electronic properties of these oxides, with atomic resolution and in real space and sensitivity to single atoms [14]. EELS chemical imaging with atomic resolution has been achieved [15-17]. Furthermore, in perovskites the O 2p bands and the transition metal 3d bands are very close to the Fermi level so the electronic properties can be probed by studying the fine structure on the O K edge and the transition metal L edge.

Here, we study the interaction between a high T_c superconductor and a manganite with colossal magnetoresistance by these techniques. High quality superconducting/ferromagnetic YBCO/LCMO and superconducting/antiferromagnetic $\text{YBa}_2\text{Cu}_3\text{O}_{7-x}/\text{LaMnO}_3$ (YBCO/LMO) superlattices grown by high pressure oxygen sputtering [2-4] were studied in a scanning transmission electron microscope (STEM) equipped with a Nion aberration corrector and a Gatan Enfina Electron Energy Loss Spectrometer. Both superconductivity and ferromagnetism are strongly suppressed in each other's presence [2,3]. Atomic resolution Z-contrast images show that the interfaces are coherent and free of defects [18, 19]. Elemental profiles show the interface stacking sequence to be CuO_2 -BaO-MnO₂-La/CaO-MnO₂-... [18, 19]. The absence of interfacial CuO chains explains the lack of superconductivity in ultrathin YBCO layers (1 or 2 unit cells thick) sandwiched in between manganite layers.

EELS measurements in ferromagnetic/superconducting LCMO/YBCO superlattices suggest significant hole enrichment in the manganite together with electron localization in the superconducting side of the interface, while density-functional theory shows how the first manganite layer at the interface has a lower magnetic moment than expected according to the nominal doping. Interpretation of the energy loss fine structure in terms of charge transfer from the ferromagnet will be discussed. As a result, superconductivity is suppressed in the superconductor, and the magnetization in the ferromagnet interface layer is depressed [6]. Interestingly, in antiferromagnetic/ supercon-

ducting LMO/YBCO superlattices ferromagnetism is induced in the LMO when its thickness is above five unit cells. The onset of ferromagnetism is accompanied by a strong depression of the superconductivity, similar to that found in LCMO/YBCO superlattices. The possibility of charge transfer at the interfaces being involved in this phenomenon will also be examined. Since interface vacancies may also be present and condition the system properties their role will also be discussed. Introduction

To understand the unexpected ferromagnetism shown in the d^0 oxide film of HfO_2 [1], we have studied the d^0 oxide film of ZrO_2 with oxygen-vacant, which shows bistable resistive switching between high-resistance (HR) and low-resistance (LR) states by applying external voltage at room temperature. We find that the HR state is ferromagnetic and insulating and the LR state is non-magnetic and metallic. This suggests that the magnetic phase in our d^0 thin films is strongly coupled with the electric memory state induced by an external electric field. HR ferromagnetism of our ZrO_2 thin film achieved at room temperature can generate new functional spin devices, such as electric-field-controlled magnetic data storage and magnetically recorded ferroelectric memory devices, in which the electric field is used as an alternative means for controlling the magnetic configuration.

Experimental details

Our experiments were carried out with ZrO_2 thin films made by dc reactive sputtering. During deposition, the substrate temperature and the working pressure of the ($\text{Ar}+\text{O}_2$) gas were kept at 300 °C and 5 mTorr, respectively. The ratio of the O_2 partial pressure to the working pressure was lowered to 5% to make oxygen-vacant samples. For transport measurements, 100- μm -diameter Pt top electrodes were deposited at room temperature by dc sputtering with a shadow mask. Micro manipulated probe station was used for transport measurements. The magnetic properties were characterized with a superconducting quantum interference device magnetometer.

Results and discussion

Fig. 1 shows the typical current-voltage (I-V) characteristics of our ZrO_2 thin films. The application of a voltage induces reversible switching between the HR and the LR states with slightly capricious switching voltages. This bistable resistance switching is applicable to nonvolatile resistance random

access memory (RRAM) device. As seen in Fig. 2, the temperature dependence of the resistance of HR state plotted with $\ln R$ versus $1/T^{1/4}$, which is typical form of variable-range hopping model, is linear in the temperature regions of 150 K < T < 300 K and 50 K < T < 150 K. The best fit gives the values of $T_0 = 6.8$ eV and 28.4 meV in the high- and the low-temperature regions, respectively. On the other hand, the resistance decrease of the LR state on cooling is suggestive of a metallic nature. Fig. 3 shows the hysteresis loop of HR state at room temperature. The coercive field is about 50 Oe, and it saturates above 1.5 kOe. One of the simplest models to explain the high-resistance state

for slow-moving electrons in a dielectric crystal is a lattice polaron model, leading to a high-resistance state. In an analogous manner to the lattice polaron, if an electron tends to distort the magnetic polarization in a magnetic material, then it would induce a local ferromagnetic ordering, this is called a bound magnetic polaron model [2].

Conclusion

From the results in our d^0 ZrO_2 films, we can elucidate the fact that the magnetic phase can be controlled by an electric field. These ferromagnetic and insulating phases at HR state are intrinsic and can be understood in terms of bound magnetic polaron model.

Perovskite-oxide pseudo spin valve structure.

Y. Chan, W. Cheng, H. Lau, C. Leung

Department of Applied Physics, The Hong Kong Polytechnic University, Hong Kong, China

Giant magnetoresistive (GMR) effect has been extensively studied in both theoretical and practical aspects. While most of the investigations were focused on metallic multilayers, only a few studies have demonstrated GMR in all-oxide structures.

In this work, we fabricated all-perovskite oxide pseudo spin valve (PSV) structures. LaNiO_3 (LNO), a Pauli paramagnet with high electrical conductivity [1], was used as the spacer material. For ferromagnetic electrodes, $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ (LSMO) and $\text{La}_{0.67}\text{Sr}_{0.33}\text{Mn}_{0.95}\text{Ru}_{0.05}\text{O}_3$ (LSMRO) were chosen. Bulk LSMO is ferromagnetic at room temperature, has been predicted to be half metallic, and has a fairly good conductivity [2]. On the other hand, substitution of Mn by Ru in LSMO could lead to an enhanced coercivity compared with LSMO, while retaining the high Curie temperature and conductivity [3]. Since a sharp steplike magnetoresistance can be achieved in PSV only when there is a high contrast in coercivities between two ferromagnetic layers, LSMRO was a suitable candidate material for the ferromagnetic electrode layer. Crucially, the perovskite structures of all the three materials, with similar lattice parameters ($a_{\text{LNO}} = 3.84 \text{ \AA}$, $a_{\text{LSMO}} = 3.87 \text{ \AA}$, $a_{\text{LSMRO}} = 3.86 \text{ \AA}$), permitted epitaxial growth of the structure under suitable conditions.

LSMRO(100nm)/LNO(15nm)/LSMO(50nm) PSV structure was deposited on LaAlO_3 (LAO) (001) substrates by pulsed laser deposition. All the layers were deposited under an oxygen pressure of 150mTorr. The substrate temperature required for the deposition of LSMRO film (830°C [3]) was higher than that of LNO and LSMO (650°C); the combination of such a high substrate temperature and oxygen pressure avoided Ru deficiency in the final films due to its high volatility [3]. Therefore, LSMRO was deposited as the bottom layer to minimize interdiffusion effect among different materials.

Fig.1 depicts the X-ray diffraction profile of a trilayer film sample. The lattice parameters of LNO and LSMO were so close that they could not be separated from the scan. For the LSMRO, the 5%-Ru doping has caused an enlargement of the lattice parameter in the film, which was similar to the observation by Yamada et al [3]. Temperature-dependent resistance measurements of single-layer LSMO and LSMRO films on LAO (001), 50 and 100 nm in thickness, indicated Curie temperatures of 330°C for both layers.

Fig. 2 shows the hysteresis measurements of the PSV at various temperatures, down to 77 K. As the temperature was reduced below 200 K, a double-coercivity behaviour was observed in the sample. At 77 K, the coercivity of LSMRO was about 300 Oe, approximately five times the coercivity of the LSMO layer. This clearly indicated the coercivity enhancement effect by Ru doping in LSMO. Fig.3(a) shows the current-in-plane MR measurements of a PSV sample at 10 K, with current applied parallel and perpendicular to the external field. The corresponding measurements of LSMRO is illustrated in Fig. 3(b), which showed clear signs of anisotropic magnetoresistance (AMR) effect. On the other hand, no AMR effect was observed in LSMO single layer samples (data not shown). A direct comparison of Fig. 3(a) and (b) clearly indicated AMR contributions of the LSMRO layer to the transport behaviour of the PSV at high magnetic fields ($\sim 500 - 700 \text{ Oe}$). Yet at low fields values ($\sim 150 - 200 \text{ Oe}$), a pair of resistance peaks were observed for the measurements of PSV in orthogonal directions. These are signs for the occurrence of GMR in the PSV sample.

Grain-size effects on magnetic properties of sputtered Co₂MnSi films.

S. Ladak², A. Hirohata¹

1. Department of Electronics, University of York, York, United Kingdom; 2. Department of Physics, University of York, York, United Kingdom

In order to exploit 100% spin polarisation induced by spontaneous magnetisation, a half-metallic ferromagnet (HMF) has been intensively investigated [1]. The HMF possesses a bandgap δ at the Fermi level E_F only for its minority spins, achieving 100% spin polarisation at E_F , however, to date there has been no experimental report on the half-metallicity at room temperature (RT), which is crucial for future device applications. Among theoretically proposed HMFs, the Heusler alloys hold the greatest potential to realise the half-metallicity at RT due to their high Curie temperature (above RT), lattice constant matching with major substrates (such as III-V semiconductors and MgO), and large δ at E_F in general. Recently, a magnetic tunnel junction (MTJ) with an epitaxial L₂₁ Co₂MnSi film has been reported to show very large tunneling magnetoresistance (TMR) ratios of 70% at RT and 159% at 2 K [2]. These are the largest TMR ratio obtained in a MTJ with a Heusler alloy film and AlOx barrier. Even so, such rapid decrease in the TMR ratio with increasing temperature does not follow the temperature dependence of the magnetisation, suggesting that a small fraction of atomically disordered phases cannot be ignored in the spin-polarized electron transport at a finite temperature. The elimination of such disordered phases, especially near the barrier interface, improves the TMR ratios further and realizes the half-metallicity at RT. In this study, we fabricate polycrystalline Co₂MnSi films with controlled grain sizes by sputtering in order to investigate both magnetic and structural properties of both grain-boundary and bulk regions.

Samples were prepared using a controlled plasma HiTUS sputtering system [3], where the target bias was adjusted to deposit Co₂MnSi films with a series of grain sizes. MgO(001) substrates were cleaned with acetone and annealed at 573 K for 20 min. at a base pressure of 3×10^{-5} Pa. The plasma was generated by an RF field at 3×10^{-1} Pa Ar pressure and steered onto a target with a DC bias from -250 to -990 V, giving control of the deposition rate. This results in the change of grain size. The Co₂MnSi film thickness was maintained at 23 nm with a 2nm thick Ru capping layer. These films were annealed at 760 K for 3 hours. Magnetisation curves were measured with using a PMC AGFM. The grain size analysis was carried out by TEM, and the crystalline structures were characterised by X-ray diffraction (XRD).

Figure 1 shows the magnetisation curves of the films after annealing. The films provide almost no magnetic moment before annealing. It is well established that the grain size becomes larger with increasing bias [3]. The coercivity H_C decreases with increasing the target bias and hence increasing grain size. The film grown at -990 V shows H_C of 16 Oe, which is comparable with that for a highly ordered Co₂MnSi film [4]. Since the measured magnetic moment per formula unit is much larger than the theoretically calculated value from a generalised Slater-Pauling curve ($5 \mu_B/\text{f.u.}$) [5], the sample grown at -500 V with smaller grain sizes may contain segregated phases as well as the Co₂MnSi crystallites. These results suggest that the two regions in the films, grain boundary and bulk, evolve different magnetic properties after annealing: the films with smaller grains have their magnetic behaviour dominated by the grain boundaries, while those with larger grains exhibit bulk properties. Grain-size analysis by TEM structural characterisation by XRD further supports this finding.

Giant tunneling magnetoresistance (TMR) value has been achieved with half metallic Heusler alloys as the ferromagnetic electrodes [1]. One of the problems in achieving higher TMR values is the temperature dependence of the half metallicity of the Heusler alloys which is attributed to the presence of the Fermi level near conduction band. Another possible reason for the degradation of the half metallicity of the Heusler alloys is the magnon effect on the spin polarization, which was theoretically explained by Bratovsky et. al. [2], where one mode of magnons is thought to degrade the spin polarization, whereas phonons enhance it.

One of the possible ways of solving this problem is to dope a rare earth element to Heusler alloys to suppress the magnons. Doping of rare earth elements in soft magnetic alloys for enhancing the magnetic damping is a well known phenomenon [3], which is already implemented in the ultrafast magnetic recording heads and MRAMs. In the present study we have not studied the magnon suppression effect in Heusler alloys directly; rather, we are interested in the direct measurement of spin polarization and the effect of rare earth doping on it. Hence in the present study we have chosen Nd as a dopant in the Mn site of Co_2MnSi . The spin polarizations (P) were measured using the point contact Andreev reflection (PCAR) method.

The alloys were prepared by induction melting in a quartz tube and then wedge casted. These were annealed at 800°C for 48 h in a quartz tube. The phase characterization was carried out by using x-ray diffraction (XRD). The spin polarizations were measured with the PCAR technique at 4.2K. Thin Nb wire was electropolished and used as a superconducting tip for observing the Andreev reflection. The obtained conductance curves were then fitted with the modified BTK model to extract the spin polarization. The fitting parameters were, spin polarization (P), superconducting gap (Δ) and interfacial scattering parameter (Z) [4].

From Figure 1(a), in the XRD pattern the presence of the (111) and (200) superlattice peaks indicates that the annealed $\text{Co}_2\text{Nd}_{0.05}\text{Mn}_{0.95}\text{Si}$ alloy has the L_{21} ordered structure with some unidentified extra phase. However, Figure 1(b) is the XRD pattern of Co_2MnSi which was taken as a reference.

Figure 2(a), (b) and (c) shows the conductance curves obtained from the point contact measurements on a $\text{Co}_2\text{Nd}_{0.05}\text{Mn}_{0.95}\text{Si}$ alloy. Figure 2(d) shows a P vs Z curve, the intrinsic spin polarization was determined to be 0.58 by extrapolating the curve to $Z = 0.0$. From our previous results, the spin polarization obtained for Co_2MnSi was 0.56 using PCAR. Hence, we can conclude that the Nd addition has enhanced the spin polarization of Co_2MnSi . Within the point contact measurements regime, the values measured by several authors on thin films and single crystals of Co_2MnSi has shown only a spin polarization of 0.48~0.56 [5]. The values of spin polarizations obtained by the PCAR method are far from the ideal 100% spin polarization. The spin polarization reported by Sakuraba et al [1] is the only report which shows ideal half metallic nature measured from a tunneling magnetoresistance value of a magnetic tunneling junction. This is considered to be a tunneling spin polarization rather than the intrinsic spin polarization. But the PCAR method gives the intrinsic transport spin polarization of the conducting electrons, and the value of 0.58 for the Nd doped Co_2MnSi is a relatively higher value.

From our PCAR measurements we conclude that the spin polarization (P) value is enhanced with Nd doping in the Co_2MnSi alloy. Hence this alloy could be a potential material to enhance the TMR

values if incorporated into a magnetic tunneling junction. It would be interesting to see the effect of rare earth doping in Heusler alloys theoretically.

Half-metallic ferromagnets (HMF) are materials where one of the spin-channels is metallic and the second one is insulating at the Fermi Level. These materials show full spin polarization at the Fermi level and have triggered a lot of interest due to their potential use in spintronic applications. Several HMF have been predicted by means of electronic structure calculations, for instance, some Heusler alloys like Co_2MnGe . Co_2MnGe are considered as excellent candidates for such spintronic applications, since the Curie temperature is high (905 K) and there is a good lattice matching with the GaAs semiconductor family [1]. Despite the numerous works on such materials, few of them have been devoted to the magnetic properties. We have therefore studied the magnetic anisotropy and the dynamic properties of Co_2MnGe thin films with conventional ferromagnetic resonance (FMR) and microstrip line FMR spectroscopy (MS-FMR).

Co_2MnGe films of 30, 50, 75 and 100 nm in thickness were grown by RF-sputtering at an Ar pressure of 5×10^{-3} mbar on Al_2O_3 a-plane substrates at a growth temperature of 470°C. Before deposition of the Heusler film, a seed layer of V, 4 nm thick, was deposited in order to induce (110)-growth of the Heusler layer [2]. A final protective overlayer of gold, 4 nm thick, was grown on top of the film.

Magneto-optical Kerr effect (MOKE) was used at room temperature to obtain the hysteresis loops with the applied field parallel to the sample edges. For the dynamic measurements, our 22 GHz conventional FMR set-up is described in [4]. In the case of MS-FMR, the magnetic sample is mounted on a microstrip line used to excite its magnetization. This microstrip line is connected to microwaves generator (2-18.6 GHz) and to a Schottky detector used to measure the transmitted power. At each external applied field, the sample is swept through the resonance condition by varying the microwave frequency. When the magnetic sample undergoes a ferromagnetic resonance, the microwave losses are increased and the transmitted power changes slightly. In addition, the external magnetic field is modulated with amplitude of 4 Oe at a frequency of 170 Hz. This modulation allows lock-in detection to be used in order to increase the signal-to-noise ratio. The measured signal is proportional to the field derivative of the imaginary part of the rf susceptibility as function of the microwave frequency. The resonance frequencies and fields are obtained from the Lorentzian-derivative fit of the obtained results by MS-FMR and FMR, respectively. In contrast to the conventional FMR, MS-FMR allows dynamic measurements over a large frequency range and on low applied external fields not sufficient to hide the effect of the small magnetic anisotropies.

The study of spin wave frequencies in dependence of the in-plane sample orientation allows for the determination of anisotropy constants of thin magnetic films while the out-of-plane angular dependence gives the effective magnetization. These in-plane and out-of-plane angular dependencies of the different resonance frequencies (at 110 Oe) and fields for the 50 nm thick sample are represented on Fig.1a and Fig.1b, respectively. The sample exhibits a clear predominant four-fold magnetic anisotropy beside a uniaxial anisotropy along (110). This uniaxial anisotropy is most probably induced by the growth condition as far as the Co_2MnGe films are FCC. From the in-plane and the out-of-plane resonance field values (Fig. 1b), the effective magnetization ($4\pi M_{\text{eff}}$) and the g-factor are calculated ($g=2.17$) using the Kittel formula. These values are then used to fit both the in-plane angular- and the field-dependence of the resonance frequency (Fig. 1c) to determine the

uniaxial ($H_u=2K_u/M_s$) and the fourfold anisotropy fields ($H_2=4K_4/M_s$) using the theoretical model presented in [4]. The obtained values for the different samples shows that the fourfold anisotropy is predominant for all the samples. Within the experimental uncertainties the effective magnetization seems to be independent on the samples thickness suggesting a weak out-of-plane anisotropy. The in-plane anisotropies and the effective magnetization are maximal for the 50 nm thick film. This is maybe due to the fact that the 50 nm sample was sputtered two months before the other samples. From the field separation between the perpendicular standing spin-wave mode and uniform mode FMR resonance fields, the exchange stiffness was estimated to be 0.98×10^{-6} erg/cm. The magnetization at saturation and exchange constant of this material are very closed to those of permalloy. Finally, a room-temperature resistivity of 110 $\mu\Omega$ cm has also been determined.

Co-based full Heusler alloys represent nowadays a class of materials with a high potential for application in the growing field of spintronics. This is due to their high Curie temperatures and their theoretically predicted minority-spin gap, resulting in a high spin polarization at the Fermi level. For spintronics applications, the spin polarization must be high not only in the bulk, but also at the surface region. This is not straightforward, since extrinsic as well as intrinsic mechanisms can reduce the spin polarization in the surface region. In fact, the highest spin polarization value measured so far with a surface sensitive technique at room temperature was reported by Wang et al. [1] for a single crystalline Co_2MnSi film, showing a spin polarization of 12% at the Fermi level.

In a recent paper, the highest Heusler surface spin polarization value of 45% was measured at the surface of a $\text{Co}_2\text{Cr}_{0.6}\text{Fe}_{0.4}\text{Al}$ (CCFA) sample by spin resolved photoemission with the 4th harmonic (50 fs FWHM, 5.9 eV) of a pulsed laser oscillator system [2]. It has to be pointed out that these results were obtained at room temperature and in magnetic remanence. Though the preparation procedure leads to reproducible results, the systematic investigation of the morphology changes at the surface during annealing was still lacking.

In this contribution we present results of systematic LEED and Auger studies of the surface properties obtained after progressive annealing cycles. CCFA samples differing in substrate and/or buffer layer have been investigated. We conclude that no high spin polarization values can be measured unless the surface structure and relative composition of the alloy elements is stable and bulk-like. This can only be achieved above annealing temperatures of 400°C.

In this case, both LEED and X-ray diffraction show high geometric ordering in all samples. A typical LEED picture taken at $E=73$ eV after annealing up to 450°C is shown in figure 1. Also the chemical surface composition stabilizes at this temperature. Furthermore in samples with a Fe buffer layer, as used in [2], Auger spectra show that the iron content at the surface rises due to inter-diffusion from the buffer layer. This can also be seen in Total Electron Yield X-ray absorption measurements and has positive influence on the functionality of GMR devices [4].

In the surface spin resolved electron spectra (figure 2) a peak in the minority electron channel evolves at 0.5 eV binding energy, as predicted in calculations by Wurmehl et al. [3]. The spin polarization at the Fermi level remains positive as a consequence of the reduced density of states for the minority carriers due to the predicted minority gap, which can be seen clearly for all samples above the proposed minimum annealing temperature.

The Different Capping Layer Influence on the Magnetic, Electronic and Structural Properties of the Co₂MnGa/GaAs(100) Hybrid Structure.

S. Hassan¹, J. S. Claydon¹, W. Zhang¹, Y. Xu¹, C. D. Damsgaard², J. B. Hansen², C. S. Jacobsen², G. Van der Laan³

1. Electronics, University of York, York, United Kingdom; 2. Physics, Technical University of Denmark, Lyngby, Denmark; 3. Daresbury Laboratory, Warrington, United Kingdom

In order to design magnetic materials for specific applications, it is important to understand the effect of all the elements in the device. In this respect, it is essential to study the changes in the magnetic properties of the magnetic materials when capped with different types of materials. We report here the effect of the different capping layers, namely, Al and Au, on the magnetic, electronic and structural properties of Co₂MnGa/GaAs(100) hybrid structure. Co₂MnGa is a full Heusler alloy which is very promising for spintronic applications. It has an L21 structure, high Curie temperature and has been predicted to be half-metallic [1]. The combination of Co₂MnGa with GaAs, due to the fairly low lattice mismatch [2-4], is very significant to integrate magnetic materials with the current semiconductor technology.

Two sets of samples with different thicknesses (4.7, 6.6 and 8.5nm) have been grown using MBE on top of GaAs(100) substrates and capped with 2nm layer of either Al or Au. The XAS and XMCD measurement have been carried out on station 1.1 of the SRS at Daresbury Laboratory. From the XAS measurement, the Al-capped samples showed a pronounced shoulder after the Co L3 peak, which could be attributed to the photoelectron scattering from the ordered superlattice of the L21 structure[5]. However, this feature was absent in the Au-capped samples, which suggests that the Al-capped samples have more L21 ordered structure than the Au-capped samples. Also, the general shape of the Mn L_{2,3} edge of the Au-capped samples exhibited a fine structure, that could be explained by the localization of 3d electrons as a result of the strong hybridization between Mn and Au atoms at the interface. This hybridization has a tendency to localize the Mn electronic energy levels and leads to the observed structured absorption edges.

The XMCD measurements have been analysed using the Sum Rule and the total moment for Co and Mn have been calculated (as shown in table 1) and found to be generally very small compared with the experimental data of the bulk Co₂MnGa, which might be attributed to a local atomic disorder either by interchange of Co and Mn atoms or by partial occupancy of the Mn sites by Co atoms. Interestingly, the total moment for the Co atoms in the Au-capped samples has been enhanced in comparison with that of the Al-capped films. This effect could be associated with the hybridization of Co and Au atoms at the interface, which gives rise to an out of plane magnetic anisotropy.[6]

The magnetic properties have been measured using AGFM along in plane and out of plane directions as shown in figure 1. While a fast in plane saturation has been observed for the Au capped samples, the Al capped samples didn't show this effect, which confirm that a possible hybridization of Au and Co atoms at the interface have happened especially that it becomes less pronounced along the out of plane direction, which means that we have out of plane anisotropy. This is correlated with the enhancement of the total magnetic moment of the Co atoms in the Au-capped samples.

In addition, the out of plane hysteresis loops showed an interesting double switching for both kinds of capped samples, which could be attributed to the independent switching of a possible intermixed layer at the film interface with the substrate. For a similar reason, the quenching of the fast magnetic saturation along the out of plane direction could be explained by the hybridization between

Au and Co and Mn atoms could result in an interface layer saturated independently. This symmetry breaking could also be responsible for the less L21 structure observed by XAS in the Au capped samples compared to the Al capped samples.

Penetration depth of transverse spin current in ferromagnetic metals.

T. Tomohiro^{1,2}, Y. Satoshi³, I. Hiroshi¹, A. Yasuo³

1. Nanotechnology Research Institute, National Institute for Advanced Industrial Science and Technology, Tsukuba, Japan; 2. Institute of Applied Physics, University of Tsukuba, Tsukuba, Japan; 3. Department of Applied Physics, Graduate School of Engineering, Tohoku University, Sendai, Japan

The field of current-driven magnetization dynamics (CDMD) [1] has drawn enormous attention because of its potential applications to non-volatile magnetic random access memory and microwave devices. CDMD is also important from a scientific point of view since it provides much information about non-equilibrium dynamics of the magnetization and physics of spin transport and spin relaxation. In the last decade much effort has been devoted to studying the physics and applications of CDMD both theoretically and experimentally [2].

The penetration depth of the transverse spin current is one of the most important quantities in CDMD, over which the travelling electrons transfer their transverse (perpendicular to the magnetization) component of the spin angular momentum to the magnetization and exert a spin transfer torque on it. There is a controversial issue regarding the penetration depth of the transverse spin current. One argument is based on the ballistic theory of electron transport [3], and the penetration depth is on the order of a few angstroms. The other is based on the Boltzmann theory of electron transport [4], and the penetration depth is on the order of a few nanometers. There are few experiments that measured the penetration depth of the transverse spin current. Urazhdin et al. analyzed the CPP-GMR of noncollinear magnetic multilayers and concluded that the penetration depth of the transverse spin current in NiFe is 0.8 [nm] [5]. Chen et al. analyzed the critical current of the CDMD in the Co/Cu/Co trilayer system and concluded that the penetration depth of the transverse spin current in Co is 3.0 [nm] [6].

We study the penetration depth of the transverse spin current in ferromagnetic metals by using the spin pumping [7] in magnetic multilayers both theoretically and experimentally. We consider the Cu/F1/Cu/F2/Cu five-layer systems, where the F1 and F2 layers are made of different ferromagnetic metals and their magnetization vectors are aligned to be parallel each other. When we apply the oscillating magnetic field whose frequency is the same as the resonant frequency of the F1 layer, the magnetization of the F1 layer precesses and the spin current is pumped into the other layers. Since the magnetization vector of the pumped spin current is perpendicular to the magnetization vector of the F1 layer and the precession angle is very small (about 1 [deg]), the dominant component of the pumped spin current is perpendicular to the magnetization vector of the F2 layer. Therefore, it would be possible to determine the penetration depth of the transverse spin current in the F2 layer if we could analyze the dependence of the enhancement of the Gilbert damping constant on the thickness of the F2 layer. We measured the FMR spectrum line width of the F1 layer as a function of the thickness of the F2 layer, and observed the clear increase of the line width with increasing the thickness of the F2 layer as shown in Fig.1. To analyze the experimental results, we extend the conventional theory of spin pumping [7] by taking into account the finite penetration depth of the transverse spin current. In Fig.1 (a)-(c), the theoretical fits are shown by solid lines. The estimated values of the penetration depth of the transverse spin current in NiFe, CoFe and CoFeB are 3.7 [nm], 2.5[nm] and 12.0 [nm], respectively [8]. We will report the details of our study and analysis of the penetration depth of the transverse spin current in other ferromagnetic materials.

Effect of Spin Memory Loss at Interfaces of Ferromagnet/Normal Metal on Spin-Transfer Torque.

S. Lee, K. Lee

Korea University, Seoul, South Korea

The spins of conduction electrons are polarized when an electrical current passes through a ferromagnet (FM) because the conductivities of FM are spin-dependent. The spin-polarized current exerts a torque on the noncollinear magnetization of the neighboring second FM, i.e. spin-transfer torque (STT), resulting in a new class of magnetization dynamics [1, 2]. The STT attracts a considerable interest because of its rich physics and potential for possible applications using current-induced magnetization switching, high frequency precession, and domain wall motion. Both from the fundamental standpoint and, in view of application, it is important to *quantitatively* estimate the magnitude and angular dependence of STT for a spin valve structure.

The drift-diffusion theory [3-6] is one of the theoretical approaches to calculate spin torque term (in-plane torque, a) and field-like term (out-of-plane torque, b) of the modified Landau-Lifshitz-Gilbert equation. Although this theory provides an analytic result, which is a great merit, it has several demerits such as idealization of the Fermi surfaces, impossibility to distinguish electrons propagating in different directions, and ignoring the spin-flip scattering at interfaces. However, the drift-diffusion theory was found to be successful in at least *qualitatively* predicting the angular dependence of STT, verified in the recent experiment corresponding to the so-called “wavy STT” [7, 8].

In spite of the *qualitative* agreement between the experimental result and the present drift-diffusion theory, a *quantitative* estimate of STT is highly desired for the application of the current-induced magnetic excitation. To realize this, the demerits listed above should be resolved. In this work, we relaxed one of the demerits of the present drift-diffusion theory related to the spin-flip scattering at interfaces, i.e. spin memory loss. In our model, the spin memory loss is considered by replacing an interface as a virtual bulk layer with a finite spin-flip length. We verified our model by comparing with the model used for the “wavy STT” in Ref. [8] assuming no spin memory loss at the interfaces, and found perfect agreement when we also ignored the spin memory loss.

In this work, we investigated the effect of spin memory loss on the STT. We found the spin memory loss significantly affects the magnitude and angular dependence of STT. One striking result is that the STT is not perfectly diminished although the spin memory loss is 90%, i.e. most spins are flipped when passing through the interface. The STT at the parallel magnetic configuration (P) is smaller than that at the anti-parallel configuration (AP) when the spin memory loss is negligible, resulting in the well-known asymmetric switching current density J_C , i.e. $J_C^P > J_C^{AP}$. The STT^P increases or slightly decreases and STT^{AP} significantly decreases with increasing the spin memory loss because of a different role of the spin memory loss on the transverse component of the spin accumulation (Fig. 1). When the spin memory loss is high, STT^{AP} is smaller than STT^P , i.e. $J_C^P < J_C^{AP}$. We compared the J_C^P/J_C^{AP} obtained from our model with the experimental results using Cu/Co/Cu/Co [9] and Cu/Py/Cu/Py [10] spin valve structures at 4 K. Best fits were obtained at the spin memory loss of about 30% which is in good agreement with experimentally determined spin memory loss by using giant magnetoresistance (GMR) measurement [11]. Our results evidence the close relation between GMR and STT.

Magnetic and structural properties of fully epitaxial Fe₃O₄/MgO/GaAs(100) for spin injection.

P. Wong¹, W. Zhang¹, Y. Xu¹, S. M. Thompson²

1. Spintronics and Nanodevice Laboratory, Department of Electronics, University of York, York, United Kingdom; 2. Department of Physics, University of York, York, United Kingdom

We report on successful growth of epitaxial Fe₃O₄ on GaAs(100) with an epitaxial MgO tunnel barrier by a combined technique of molecular beam epitaxy (MBE) and post-growth annealing of epitaxial Fe in an oxygen atmosphere. The quality of the magnetite films fabricated by our approach has also been confirmed with XPS, XMCD, RHEED and MOKE[1]. From the in-situ RHEED pattern shown in Fig. 1(a), a sharp (1 × 1) reconstructed GaAs surface was identified. The MgO layer was then grown by e-beam evaporation at a rate of 2 Å/min, while the substrates were kept at 673 K. A 3 nm thick epitaxial magnetite film was then fabricated by post-annealing of Fe grown at RT. Fig. 1(b) shows that the RHEED images of the MgO layer epitaxially grown on the GaAs(100) were streaky with several elongated spots indicating the presence of some small crystalline islands on the smooth surface of the MgO film. This could be explained by the fact that there is a large lattice mismatch (25.5%) between GaAs and MgO with an epitaxial relationship of MgO(100)[001]//GaAs(100)[001]. This is consistent with the findings from other groups[2-4]. It also suggests a cube-on-cube orientation of MgO on GaAs. The RHEED patterns in Fig. 1(c) also indicate that the epitaxial Fe film rotated 45° respect to the MgO lattice giving a small mismatch of 3.8% and an epitaxial relationship, Fe(100)[011]//MgO(100)[001]. After annealing the Fe film in an oxygen partial pressure of 5 × 10⁻⁵ mbar at 500 K for 10 mins, identical RHEED patterns in Fig. 1(d) of Fe₃O₄ were obtained as in the case of Lu *et al*[1]. However, it is noteworthy that the magnetite cell in this experiment is rotated 45° relative to the MgO because it gives an extremely low lattice mismatch (~0.33%) with the MgO layer and thus the final epitaxial relationship, Fe₃O₄(100)[001]//MgO(100)[001]//GaAs(100)[001].

Figure 2 shows the magnetic hysteresis loops for samples with t_{MgO} of (a) 0 nm and (b) 2.0 nm by MOKE. The magnetic field was applied along the major axes of the GaAs(100), i.e. [011], [001], [0-11] and [010]. Both samples showed magnetic anisotropy. A uniaxial anisotropy with its easy axis along the [0-11] direction was clearly defined for $t_{\text{MgO}} = 0$ nm. Two distinctly different mechanisms associated with “unidirectional chemical bonding” and “magnetoelastic coupling” respectively have been put forward to explain the uniaxial magnetic anisotropy in hybrid magnetic metal/semiconductor system such as Fe/GaAs[5,6]. These two mechanisms might be responsible for the uniaxial magnetic anisotropy observed here as for the sample without the MgO interlayer. The 3 nm Fe₃O₄ with $t_{\text{MgO}} = 2.0$ nm also gave magnetic anisotropy which was different. In Figure 2, the MOKE observations show a predominant in-plane four-fold cubic magnetocrystalline anisotropy giving rise to global easy axes along <001> of the GaAs. Another interesting effect of inserting the MgO barrier is the increase of the cubic anisotropy. Such increase can be accounted by the nearly perfect lattice match between Fe₃O₄ and MgO (~0.33%) compared to that between Fe₃O₄ and GaAs (5%). To quantitatively compare and evaluate the change in the magnetic anisotropy in the samples, we are modeling the MOKE loops with a combined cubic anisotropy and uniaxial anisotropy, which will be presented in the full paper.

The effect of screening on extracted tunneling barrier parameters.

S. Bonetti, J. Persson, J. Åkerman
Microelectronics and Applied Physics, Royal Institute of Technology (KTH), Kista-Stockholm, Sweden

The electronic transport across a tunneling barrier is one of the most studied problems in modern physics. Among the various approaches, the possibility of extracting barrier parameters (thickness and potential heights) from a simple and non-destructive transport measurement is of particular interest and utility. For this purpose, different models have been introduced [1,2], based on the Wentzel-Kramers-Brillouin (WKB) approximation. In particular, the Brinkman-Dynes-Rowell (BDR) [1] model, which treats the case of generally asymmetric barriers has been cited widely in literature. Its usefulness comes from the proposed analytical quadratic expression, which in a straightforward way allows the extraction of the barrier parameters, instead of relying on numerical simulations.

In recent years, it has been possible to grow extremely thin (few atomic layers) barriers. In particular magnetic tunnel junctions have attracted attention, due to possible applications in spintronics. On these barriers, the quadratic BDR approximation fails to predict the correct barrier parameters when the fit with experimental data is obtained, and, with the same parameters, the full BDR simulation fails to follow the quadratic trend of the experimental data at high bias voltages.

It has been proposed that the roughness of the barrier can explain the discrepancies [3]. However, with this approach one can recover the correct functional shape of the conductance curve, but not its absolute value. Here we propose that field penetration into the electrodes can explain, at least in part, the discrepancies at high bias voltages, and produce barrier parameters that are closer to the correct ones. The effect of field penetration on tunneling conductance was already introduced by Simmons [4], but his treatment was not extended to asymmetric barriers, and not to atomically thin junctions at high bias voltages.

The starting point is the observation [5] that the capacitance of thin dielectric films has an extra contribution to the geometrical capacitance, which could be explained fairly well by assuming that the applied potential was partially screened due to the finite conductance of the electrodes [6]. In free electron approximation, for barriers thicknesses around 10 Å, and for Fermi energies between 2 and 10 eV (i.e. for most of metals), 20% - 30% of the applied potential drops in each of the electrodes.

In Fig. 1 it is possible to understand the effect of introducing field penetration into the electrodes in the model. If one plots the conductance as a function of the bias squared, the parabolic trend (which is a line with such axis) is preserved to higher bias the larger the screening. This is expected, since the effect of introducing screening is for the barrier to experience a smaller bias, where the standard BDR simulation is still in the region of quadratic trend.

One can now check which is the effect of screening on fitting experimental data, taken from Ref. [3]. To estimate the goodness of the fit, we used a combined figure of merit, the product of χ^2 times the value of the fourth derivative. Since odd powers are smaller compared to even ones, we expect the fourth order terms to be the dominant ones in determining the discrepancies from the quadratic trend. Free parameters are the two potential heights and the barrier thickness, fixed the screening ratio. By this criterion, setting a screening of 30% of the bias, we found that the best fitting (shown in inset) parameters are: $\phi_1 = 0.9$ eV, $\phi_2 = 1.1$ eV, $d = 10$ Å. The extracted barrier thickness is closer to the experimental one ($d = 13$ Å), compared to the value $d = 7.3$ Å in Ref. [3].

Recently, it has been proposed that the band structure of the insulator in the tunneling junction must be considered in the problem [7], and this is probably the fundamental factor that lies behind the failure of the BDR model. However, while band structure is a property of the barrier, screening is related to the electrodes, and we believe it is therefore a complementary part of the problem, and probably the full solution requires considering both effects. It is interesting to note that if the band structure is approximately introduced into the model by using an effective mass $m^* = 0.4 m_e$, where m_e is the free electron mass, we get a best fitting with $\phi_1 = 1.5$ eV, $\phi_2 = 1.9$ eV, $d = 13.1$ Å, when the screening is set to 20% of the applied bias, in an even better agreement compared to the previous case.

Rectification effect in the medium with noncoplanar magnetic structure.

O. G. Udalov, A. A. Fraerman

Institute for physics of microstructures RAS, Nizhny Novgorod, Russian Federation

The interplay between the spin and spatial degrees of freedom of electrons is of great interest from both a theoretical and a practical point of view [1]. Investigations into this interplay are based on two well-known effects: spin-orbit coupling and Zeeman splitting. When hamiltonian contains Zeeman term (for example, ferromagnetic metals in the frames of s-d approximation) the electron energy spectrum depends on a magnetic field (or magnetization) spatial distribution. Up to date, there are a lot of works dealing with systems with collinear and non-collinear but coplanar magnetization distribution. Systems with non-coplanar magnetization distribution are poorly investigated. However, the later has essential peculiarity: momentum-reversal symmetry is broken there. It is easily can be seen from Schrodinger equation with Pauli term included. Such an equation is not invariant with respect to complex conjugation if magnetization distribution is non-coplanar. Broken symmetry can lead to the peculiarities in transport properties of crystals.

One of the consequences of momentum reversal symmetry breaking was considered theoretically in works [2,3]. A mesoscopic metal ring with a magnetic texture was studied there. It was shown that, when the distribution of magnetization in the ring became non-coplanar, persistent electrical current occurred in the ring. The magnitude of this current is proportional to the degree of non-coplanarity of the magnetization distribution. The effect viewed in [2,3] is originated from the spectrum quantization in the ring. Therefore, it decreases to zero with the increase of the ring size (even in the absence of inelastic scattering).

This work is devoted to investigation of macroscopic effects arising due to momentum-reversal symmetry breaking in systems with non-coplanar magnetization distribution. In our work it is theoretically demonstrated that rectification (diode effect) should occur in the systems with non-coplanar magnetization distribution.

Phenomenological theory is built for rectifying effect occurring due to exchange interaction in the ferromagnetic medium. It is shown that third rank rectification tensor is non-zero only for the mediums with non-coplanar magnetization distribution.

Microscopic theory of rectifying effect is built for particular case of non-coplanar system - magnetic spiral. Formalism of Boltzman equation is used for calculations. It is shown that in the region of low frequency of external electric field there are two mechanism of diode effect. First is asymmetry of group velocity, which arises due to spectrum asymmetry. Second mechanism is scattering asymmetry. It arises due to non-trivial form of electron wave function in non-coplanar magnetic spiral. In the region of resonant frequencies, corresponding to energy gap between two spin subbands, one more mechanism of diode effect occurs. This mechanism connected with transitions of electrons from one spin subband to another spin subband under the impact of alternative external field. Note that these transitions are caused by electric field because of heterogeneity of magnetization distribution. Similar rectifying effect was considered in work [4], but for the system with spin-orbit interaction. Resonant mechanism is stronger than two mechanisms mentioned above, but it exists only in the narrow frequency range.

Results of microscopic theory are in agreement with phenomenological one's.

Physical and electrical study of Permalloy/Al₂O₃/Si diodes for spin injection into silicon.

N. Bruyant¹, R. Benabderrahmane¹, M. Kanoun¹, C. Baraduc¹, H. Achard², A. Bsiesy³
 1. SPINTEC, CEA CNRS, Grenoble, France; 2. LETI-Minatec, CEA, Grenoble, France; 3. SPINTEC, Université Joseph Fourier, Grenoble, France

The extension of spintronics into the field of semiconductor devices has generated much interest recently. Due to the absence of ferromagnetic semiconductors at room temperature, ferromagnetic metals have been used to inject spin polarised electrons into semiconductors. Several research groups have demonstrated the injection of efficient spin-polarized electrons from a ferromagnetic metal into a semiconductor by using either a reverse-biased Schottky ferromagnetic metal/semiconductor diode [1] or a ferromagnetic Metal/insulator/semiconductor (FMIS) diode [2]. In the last case, spin injection takes place by tunnelling across an interfacial insulating layer. This tunnel barrier avoids the so called conductivity mismatch between the ferromagnet and the semiconductor which was identified as a fundamental limit to spin injection [3]. The insulating layer may act both as an electrical barrier and as a barrier against ferromagnetic atoms diffusion and therefore avoid semiconductor contamination. A further promising step in this field is the use of silicon to build a spintronic device, due to the straightforward integration in the CMOS technology. The spin polarized current injected in the silicon channel via the tunnel barrier is then analysed by a second ferromagnetic electrode (collector). The resistance between these two ferromagnetic electrodes should depend on the relative orientation of their magnetization, parallel or anti-parallel. This effect would pave the way towards a spintronic memory on silicon.

Coherent spin propagation is a necessary condition to device functionality, however it can be highly sensitive to the electrical properties of the structures such as interfacial defects, current transport mechanisms and recombination centers. So, it is necessary to avoid recombination via defects that may be induced by Ni or/and Fe diffusion either at Insulator/Si interface, in the oxide or in the substrate bulk. The presence of such defects in the oxide could induce trap assisted tunnelling (TAT) that would eventually flip the spin by spin orbit coupling. Furthermore, at the collector, the polarised electrons can be trapped by the interface defects, and, if the capture time exceeds the spin lifetime, spin polarisation can be lost. For these reasons, we have focused our study on the electrical and physical properties of the Permalloy/Insulator/Si stack which could be used as a spin injector and collector.

Samples with either thermal silicon dioxide or ALD (Atomic Layer Deposition) alumina were fabricated. To determine the contamination of silicon with ferromagnetic atoms, Time of Flight Secondary Ions Mass Spectrometry (TOF-SIMS) was performed. Two samples NiFe/SiO₂ (4nm)/Si and NiFe/Al₂O₃ (2nm)/Si were studied. The contamination level by different ferromagnetic atoms (Ni60, Ni58, Fe56) reported in Fig. 1 (left) shows different behaviours for the two samples. The sample with alumina oxide shows a lower contamination level (1E18atm/cm³) than the silicon oxide sample. From these measurements, we can conclude that the alumina is a better diffusion barrier than the silicon oxide.

A detailed electrical study is necessary in order to verify if this structure is satisfying conditions of an injection collection and detection of spins. In order to investigate interfacial defect density (Dit), well known Capacitance-Voltage analyses at high and low frequency (CHF-LF-V) were performed. We compared the interfacial defect density between two samples NiFe/Al₂O₃ (2nm)/Si. In one of them, Al₂O₃ was exposed to a densification annealing at 700°C under O₂ during 15mn. The value of Dit extracted for Al₂O₃ with densification (2E12) is more than one orders of magnitude

smaller than the extracted value for Al₂O₃ without densification (5E13) and close to those reported in the literature.

In order to investigate the transport mechanism, current-voltage characteristics were performed for the sample NiFe/Al₂O₃ (with densification)/Si at temperature ranging from 80K to 300K. These characteristics show no temperature dependence which is consistent with tunnel transport. Another indication in favor of direct tunnelling is the good agreement between our experimental data and a direct tunnelling model on more than 4 orders of magnitude of current density (Fig. 1 right). In this work, we have demonstrated that alumina is a better diffusion barrier than silicon dioxide. TOF-SIMS analysis shows a lower contamination level in NiFe/ Al₂O₃/Si sample. This observation is consistent with the electrical characterisation of the alumina barrier which allows a defect free transport mechanism thanks to good diffusion barrier properties. We conclude that Al₂O₃ might be a good candidate for spin injection into silicon.

Efficient spin injection and spin filtering in semiconductors by utilizing the k^3 -Dresselhaus spin-orbit effect.

T. Fujita^{1,2}, M. Jalil¹, S. Tan²

1. Electrical and Computer Engineering Department, National University of Singapore, Singapore, Singapore; 2. Data Storage Institute, Singapore, Singapore

Semiconductor (SC) spintronics is an emerging technology which promises to deliver devices that are faster and consume less power than electronic devices. The production of spin-polarized current in SC materials is, however, non-trivial and is presently the subject of much research interest. Some proposed methods of achieving this include direct current injection from ferromagnetic contacts, and utilizing the spin-Hall effect. An alternative method is to induce spin-current via spin-dependent tunneling of electrons through SC barriers in the presence of spin-orbit coupling (SOC) [1,2]. Specifically, the SOC spontaneously breaks spin degeneracy into two spin-split eigenstates, which are transmitted across the barrier with different probabilities. As a result, the transmitted current has a finite spin polarization. However, this proposed method inherently operates at low electron energies relative to the barrier height. It therefore suffers from extremely low electron transmission probability, rendering it impractical for real device applications.

In this work, we propose a means of overcoming this problem by injecting electrons across bulk zinc-blende semiconductor barriers with k^3 -Dresselhaus SOC in the band structure [3], where the Fermi level exceeds the conduction band offset at the contact-SC interfaces (Fig. 1(a)). This regime is realizable through appropriate engineering of gate electrodes and SC doping concentrations. We theoretically analyze the spin polarization in two SC materials, GaSb and InSb, with the respective material parameters: effective mass $m^*/m_0=0.041$ and 0.013 (m_0 is the free electron mass) and Dresselhaus SOC strength $\beta=187$ and 220 eV \AA^3 . The electronic barrier height was fixed at $U=10$ meV. Figs. 1(b) and (c) respectively show the predicted spin polarization and electron transmission probabilities as a function of the injected electron energy E , for a barrier of width 85 nm. It can be seen that although an appreciable spin polarization is achieved in the low-energy tunneling regime (i.e. for $E < U$), the practicality of utilizing this result in an actual device is unlikely, given the extremely small tunneling current (Fig. 1(c)). For higher energies beyond the tunnel barrier height, one observes vastly different transmission characteristics, in particular: (1) a resonant behaviour with sharp peaks, (2) a high transmission ($> 20\%$ for GaSb and $> 5\%$ for InSb) across all energies, with peak values approaching 100%, and (3) an increasing divergence in the transmission of the two eigenstates with increasing energy. The last trend explains the increasing amplitude of the polarization curve with E in Fig. 1(a). For the range of energies considered, the polarization peaks at around 12% for GaSb and 5% for InSb. Unlike the tunneling scheme, however, there are certain energies for which the spin polarization vanishes. Thus, a careful tuning of the electron energy is required when using the structure as a source for spin-polarized current. Alternatively, the sharp modulations in the spin polarization indicate a potential use of the structure as a highly sensitive spin filter. For example, the height of the electrostatic barrier U may be modulated by a gate bias, causing a horizontal shift in the polarization spectrum as shown in Fig. 2 for GaSb. As a result, the polarization of the transmitted current can be changed significantly by inducing small variations in the barrier height. The inset of Fig. 2 shows the polarization as a function of barrier height U for a fixed electron energy of $E=55$ meV. Evidently, one can readily modulate the polarization between its maximum and minimum values, resulting in a highly tunable spin filter. The ability to flip the spins by application of a gate bias also enables the device to function as a spin transistor; in which case, a ferromagnetic contact should be used as the collector.

In summary, we have investigated a trilayer semiconductor structure with resonant polarization behaviour and high current transmission. Our analysis indicates a potential use of the structure as a source of spin current in an SC-based spintronic device, either as a sensitive spin filter, or a novel spin transistor.

Spin polarization shift illustrated for $U=10$ meV (dashed) and 15 meV (solid) cases for GaSb barrier of width 85nm. Small changes in U (e.g. via gate bias) result in a large modulation of polarization (see inset, for $E=55$ meV fixed).

Electric field effect on spin diffusion in a semiconductor channel.

J. Kwon¹, H. Koo¹, J. Eom^{2,1}, J. Chang¹, S. Han¹

1. Center for Spintronics Research, Korea Institute of Science and Technology, Seoul, South Korea; 2. Department of Physics, Sejong University, Seoul, South Korea

The spin transport characteristics at a ferromagnet-semiconductor interface are important factors that give rise to the critical issues in the development of spin-FETs. Previous works [1-3] have reported spin injection into a metal or a semiconductor channel for systems in which the transport mechanism can be described by the spin diffusion models. In the diffusive regime, the accumulated spins evenly diffuse out in every direction and the spin signal (ΔR) decays exponentially with increasing distance between the injector and detector, L . However, if we wish to take into account spin drift induced by an electrical field (E), the spin diffusion model should be modified.

To clarify the spin drift effect, we fabricated a lateral spin valve device on a micron-sized InAs quantum well channel. In this system, the InAs channel was inserted between $\text{In}_{0.52}\text{Al}_{0.48}\text{As}/\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ double cladding layers. Figure 1(a) shows a conventional non-local measurement geometry (Geometry A) in which the charge current does not flow between the voltage probes. This geometry provides a robust method for measuring spin injection and detection without spurious effects. Figure 1(b) shows a modified non-local geometry (Geometry B) in which the voltage probe detects part of the current path but the bias current does not directly flow into the ferromagnet-semiconductor junction of the detector. If we subtract the constant charge-current-induced voltage drop from the measured voltage, we obtain the spin dependent resistance change. As shown in Fig. 1 (a), in Geometry A the current flows from the injector (FM1) to the left end of the channel which is the opposite side of the channel from where the detector (FM2) is located. Therefore the spin distribution is biased toward the opposite side of the FM2 as described by the distribution of spin polarization, P . In Geometry B, however, the spin drift occurs towards FM2 and the spin distribution slowly decays on the side of FM2. From the experimental results, we found that ΔR of Geometry B is larger than that of Geometry A by 3.3 m Ω at $T = 60$ K.

Figure 2 shows the temperature (T) dependence of the drift effect on spin transport. At room temperature, the spin signals for Geometries A and B are clearly observable and their magnitudes are almost identical. As temperature is reduced below room temperature, the spin signals increase but the signal for Geometry B increases at a faster rate such that at $T = 20$ K, the difference between ΔR values for Geometries A and B is 5.6 m Ω . In the experiments performed to obtain the data in Fig. 2, a constant bias current of 1 mA was used. This behavior occurs because the spin diffusion effect is much stronger than the drift effect at high temperature. The diffusion constant (D) and electron mobility (μ_e) are functions of temperature and decide the critical electric field which is expressed as $E_C = D/\mu_e \lambda_0$ [4], where λ_0 is the spin diffusion length in the absence of the drift effect. Since the diffusion constant is only weakly dependent on the temperature for our InAs quantum well [1], E_C is mostly determined by μ_e and λ_0 . The magnitude of E_C is the required field at which the spin drift effect becomes the dominant factor in the spin transport; thus to determine the strength of the spin drift effect, we need to examine E/E_C . In our quantum well system E_C rapidly increases with temperature because μ_e and λ_0 decrease with increasing temperature. Therefore, E/E_C decreases with increasing temperature for a constant electric field (E).

In conclusion, we have shown experimentally the spin distribution asymmetry by measuring the spin signal of a lateral spin-valve structure in a semiconductor channel system. The magnitude of the spin signal difference due to the bias-current-induced drift effect diminishes from 5.6 m Ω at $T = 20$ K to close to zero at $T = 300$ K.

J. Inarrea¹, G. Platero

Recent transport experiments in double quantum dots show that Pauli exclusion principle plays an important role [1-5] in current rectification. Thus these devices could behave as externally controllable spin-Coulomb rectifiers with potential application in spintronics as spin memories or transistors.

We analyze the electronic transport through a double quantum dot in the regime where spin blockade occurs as a function of a DC magnetic field. We have developed a model where the Overhauser interaction between both electronic and nuclear spins and their interplay with the external magnetic field are proposed to lift spin blockade regime. Our results indicate that the current leakage experimentally observed in the spin blockade region [1], occurs mainly due to the latter spin-flip processes, affecting the electrical response and properties of the potential current rectifying device.

Triplet states, in the double quantum dot, are responsible for spin blockade. This blockade is lifted by a electron spin flip to a singlet state generating a leakage current. In our model we consider both, interdot (1,1) and intradot(0,2) singlet states, which hybridize due to singlet-triplet exchange interaction. In this scenario, two opposite flip-flop processes can occur, one gives rise to a nuclear magnetic field which supports the external one, meanwhile the other counteracts the external magnetic field. Thus the leakage current obtained strongly depends on the external magnetic field and also on the Coulomb interaction, the interdot tunneling and the level detuning between the two dots. Transport experiments at the spin blockade region show strongly non linear behavior of the leakage current as a function of the applied magnetic field including instabilities and hysteretic behavior [2-5].

Our model consists on rate equations for the charge occupations and nuclei spin polarizations in the quantum dots in the presence of Hyperfine interaction assisted by phonons, which are self-consistently solved. We analyze the current through a double quantum dot in a static magnetic field at different level detunings. The external field produces singlet-triplet crossings which increase abruptly the current due to electron-nucleus spin flip flop, giving rise to abrupt steps in the current, as experimentally observed [2,4]. The calculated current as a function of magnetic field, presents hysteresis (see Figure) which is explained in terms of the induced dynamical nuclear polarization by Hyperfine interaction.

Spin Current Characteristics in a Quantum Dot- Ferromagnetic Contacts Sandwich Structure.

W. Chen¹, M. Jalil¹, S. Tan²

1. Electrical & Computer Engineering, National University of Singapore, Singapore, Singapore;

2. Data Storage Institute, Singapore, Singapore

The injection and detection of spin-polarized current in a ferromagnetic-semiconductor-ferromagnetic (FM-SC-FM) trilayer structure has been studied intensively in recent years [1,2]. The current flowing through the system is spin-polarized due to the spin degenerate density of states (DOS) in the FM region, providing spin dependent scattering. The electrochemical potential μ becomes spin-split because of spin accumulation. For macroscopic analysis, spin current can be adequately modeled by the spin-drift-diffusion (SDD) model, a semiclassical approach based on the Boltzmann equations. Meanwhile, spintronics in the mesoscopic regime, eg. the quantum dot (QD) devices is also being actively studied. To account for the electron correlation in the central dot region and the dot-leads coupling, only the Green's function approach based on the equation of motions has been widely used [3].

Here we present an accurate theoretical treatment of spin current transport in a FM-QD-FM system, which integrates macroscopic spin transport in the FM leads with the microscopic effects of the QD in a self-consistent manner. Our model consists of a QD sandwiched between two FM bulk contacts. The spin current components J_\uparrow and J_\downarrow in the contacts are modeled by the spin-drift-diffusion equations. When electrical bias is applied, the electrochemical potential μ_σ in the FM contacts was assumed an exponential profile (Fig. 1), which splits within the spin-diffusion length of the dot-contacts interfaces and converges at the semi-infinite ends of the contacts. The QD is coupled to the FM contacts through the double tunneling barriers. The spin-polarized current flowing through the QD is calculated with the Keldysh nonequilibrium Green's function approach. We consider a single level QD with coulomb interaction energy U in the dot, so there are two conducting channels at ϵ_d and $\epsilon_d + U$. When the electrochemical potential splits at the FM-dot interface, there is a discontinuity in μ_σ at the left and right interfaces due to the QD's resistance. We assume the spin currents at the interface are continuous, i.e. no spin flipping at the interface, therefore spin current in the QD and the contacts needs to be calculated self-consistently. We showed in Fig. 2 the total charge current over the two conducting channels of the FM-QD-FM device.

The current magnitude is sensitive to the dot-contact coupling energy Γ . An increase in Γ will result in the suppression of the interfacial resistance, allowing more electrons to tunnel through the dot over a wider energy range, thereby increasing the current magnitude. The increased admixture of contact and QD states with larger Γ will also result in the broadening of the resonant current peaks, as shown in Fig. 2(a). In the self-consistent calculations, it was found that the spin asymmetry arising from the intrinsic polarization of the leads itself is insufficient to generate an appreciable spin polarization of current. This is due to the inherently large resistance of the QD. An appreciable spin polarization requires a spin asymmetric Γ , which will lead to an imbalance in the tunneling rate for spin-up and spin-down electrons. Fig. 2(b) shows a steady increase of the spin-polarization of current with the contacts polarization p , which in turn enhances spin asymmetry of the coupling strength Γ_σ . In conclusion, our self-consistent integration of the FM-QD-FM device makes it realistic for high efficient spin filters or low power spin valves in spintronic applications.

Transport of carbon nanotubes coupled to ferromagnetic electrodes.

S. Sun

Department of Applied Physics, National university of Kaohsiung, Taiwan, Kaohsiung, Taiwan

In this work, same types of magnetic electrodes are connected to both sides of carbon nanotube (CN) with zigzag heads [1], as displayed in Fig. 1. The difference between the currents in parallel and anti-parallel alignments of magnetic polarization for the electrodes in various ratios of density of states between different spins is calculated. The Hamiltonian of the system in tight-binding model through the Fourier transformation in periodic circular-direction exhibits the form,

$$H = \sum_{k, \sigma, \alpha \in L, R} \epsilon_{k, \sigma, \alpha} c_{k, \sigma, \alpha}^\dagger c_{k, \sigma, \alpha} + \sum_i e_p d_i^\dagger d_i + \sum_i \sum_{kx} t(kx) (d_i^\dagger d_{i+1} + h.c.) + \sum_{k, \sigma, \alpha \in L, R} \sum_{kx} V_\alpha c_{k, \sigma, \alpha}^\dagger d_{i+1} + h.c. \quad (1)$$

where N is the number of atomic sides in length and $N=12$ in this study; L and R index the left and right electrodes and σ is the spin index; the first term describes the kinetic energy of both magnetic electrodes indexed by L and R for the left and right sides, respectively; the second term means the orbital energy levels, e_p , for every atomic sides; the third term represents the kinetic energy of a CN by means of the hopping energy $t(kx)$, and two hopping values $t \cos(kx a/2)$ and t are alternative in hopping sites; the final term describes the coupling interaction between the magnetic electrodes and the CNs by means of the coupling constant, V_α . The discrete kx is quantized in $kx=2\pi/a$ (n/m), $n=0, 1, 2, \dots, m-1$, where m is the chiral number, $C_h=(m, 0)$ and in this study $m=10$. By means of non-equilibrium Keldysh Green's function theory, the formula of the tunneling formula has the form [2],

$$I = -2e/h \int d\epsilon \sum_{kx} [f_L(\epsilon) - f_R(\epsilon)] \sum_{\sigma} \{ [T_r(\Gamma_\sigma^L(\epsilon)) \Gamma_\sigma^R(\epsilon) / (\Gamma_\sigma^L(\epsilon) + \Gamma_\sigma^R(\epsilon)) \text{Im} G_{\sigma\sigma}^r(kx, \epsilon)] \} \quad (2)$$

The spin-dependent spectral function is $\Gamma_\sigma^{\alpha}(\epsilon) = V_\alpha^2 D_\sigma^{\alpha}(\epsilon)$ and the spin-dependent density of states in linear band approximation, $D_\sigma^{\alpha}(\epsilon) = 1/W (1 \pm \sigma r)$, for majority and minority spins are chosen $+$ and $-$, respectively, where W is the bandwidth of the electrode and the polarization ration, r , has the form, $r = (D_\uparrow - D_\downarrow) / (D_\uparrow + D_\downarrow)$; $f_\alpha(\epsilon)$ is the Fermi-Dirac function for left and right electrodes; and $G_{\sigma\sigma}^r(kx, \epsilon)$ is the retarded Green's function for an individual spin of CN.

Based on the concept of Spintronics, we calculate the magnetoresistance (MR) in various at room temperature, $T=300K$, where MR is defined as $MR = (I_p - I_A) / (I_p + I_A)$, and I_p, I_A are currents between both electrodes with parallel and anti-parallel magnetic polarization, respectively [3-5]. Our result shows the MR is remarkable at large r . In other words, electrode with small r has no application in Spintronics of CN, as shown in fig. 2. Particularly, the MR increases rapidly at initial bias then reach its saturation at a little higher bias, as shown in fig. 3. This rapid bias response for MR exhibits potential application in Spintronics.

The Effects of Cotunneling and Spin Flip on The Spin Polarized Transport in A Ferromagnetic Single Electron Tunneling Transistor.

M. Ma, M. Jalil

Department of Electrical and Computer Engineering, Information Storage Materials Laboratory, Singapore, Singapore

We study the spin-dependent transport in a ferromagnetic single electron tunneling(FM-SET) transistor consisting of an island weakly coupled to two ferromagnetic leads, and a gate electrode. We consider the contribution to the spin transport from sequential tunneling as well as higher-order cotunneling process, the latter of which has been of interest in recent experimental and theoretical research[1,2]. The cotunneling contribution becomes significant in the Coulomb blockade(CB) region, where the source-drain bias falls below a certain threshold value. In the CB region, the charging energy of one electron in the island exceeds the Fermi energy in the lead, and the resulting energy barrier renders it energetically unfavorable for sequential tunneling to occur; however, cotunneling transport is still possible since the electron exists as a virtual state in the island while tunneling from one lead to the other. Thus, in the CB region, cotunneling constitutes a major source of leakage current in a SET transistor and needs to be minimized. Luo *et al.* and Ohkura *et al.* have reported the suppression of cotunneling by using a granulated metal film island and multiple island electrodes, respectively[1].

In this work, we study the spin dependent transport through a FM-SET, specifically on the interplay between the inelastic cotunneling and spin flip processes. We consider the collinear configuration of the two symmetrical FM leads, i.e., the lead magnetizations are either parallel or antiparallel, and $p_1=p_2=p$, $R_{01}=R_{02}=R_0$, where p (R_0) is the polarization (tunnel resistance) of the lead, $R_0=(R^\uparrow+R^\downarrow)/2$, $R^\uparrow=R_0(1-p)$, $R^\downarrow=R_0(1+p)$, $\uparrow(\downarrow)$ stands for up(down) spin. The sequential tunneling current is calculated based on the orthodox theory and the master equation method, while the cotunneling contribution is obtained by applying the well-established approximation of Jensen *et al.*[2], which eliminates the unphysical divergence in cotunneling current at the threshold voltage. The calculated sequential tunneling and cotunneling currents are plotted as a function of source-drain bias (I-V) and gate voltage (I- V_g) in Figs. 1(a) to (d), for both parallel (I^P) and antiparallel (I^A) cases. For both cases, there are small but significant cotunneling contributions, especially near the threshold voltage for sequential tunneling. For the antiparallel case, both sequential tunneling and cotunneling currents are suppressed, reflecting the higher overall tunneling resistance compared to that in parallel case. However, the decrease is proportionately greater for cotunneling, so that the relative contribution of cotunneling current is smaller in antiparallel case.

We then focus on the effects of spin-related phenomena on the tunneling current in the SET transistor, namely the intrinsic spin polarization p of the leads, and the extent of spin flip (represented by spin flip rate Γ) in the island. We study the antiparallel case, which has the desired property of having a lower cotunneling contribution. We find that both sequential tunneling and cotunneling currents decrease monotonically with increasing p , as shown in Figs.2(a) to (c). The decrease of cotunneling current is more pronounced, i.e., when p changes from 0 to 0.8, the cotunneling current is reduced by about 90%, compared to a corresponding reduction of only 43% for sequential tunneling current.

Finally, we investigate whether the suppression of the relative cotunneling contribution at high lead polarization p still holds in the presence of spin flip process [see Fig.2(d)]. We find sequential tunneling is much more sensitive to spin flip in the island, while the cotunneling current hardly varies with Γ . Thus, we can utilize the spin mixing due to spin flip process to enhance the sequential tun-

neling current, while avoiding a similar increase in the undesired cotunneling current. By optimizing the spin-related properties of a FM-SET transistor, i.e., by choosing leads with high spin polarization, and by inducing high spin flip probability within the island, one can achieve a suppression of the cotunneling current relative to sequential tunneling in the FM-SET transistor. The utilization of these spin phenomena holds a distinct advantage over existing means of suppressing cotunneling by means of a multi-junction structure. The latter suffers from a lack of control and reproducibility inherent in the fabrication of multiple nanoscale junctions, as well as an excessively high resistance in the 'ON' state.

Among the challenges in spintronics, electrical injection of spin polarized current in semiconductor nanostructures is important because such nanostructures may find potential applications as spin-based devices. Different spin injectors have been proposed, including ferromagnetic or semimagnetic semiconductor contacts. The efficiency of ferromagnetic/semiconductor junctions has shown to be very small due to the large conductivity mismatch between the metal and the semiconductor.

Diluted magnetic semiconductors (DMS) are much more efficient as spin injectors, as it has been shown for contacts based in Mn. Compared to conventional semiconductor nanostructures, DMS's present an additional degree of freedom: the spin, which plays an important role in electron dynamics. In particular, in II-VI based semiconductor SLs doped with Mn carrier-ion exchange spin effects dominate the magneto-transport, producing spin polarized transport and large magneto-resistance. Exchange interaction between the spin carrier and Mn ions results in large spin splittings. Nonlinear transport through DMS SLs has been recently investigated [1]. In fact, the interplay between the non-linearity of the current as a function of the DC voltage and the exchange interaction produces interesting spin dependent feature: multi-stability of steady states with different polarization in the magnetic wells, time-dependent periodic oscillations of the spin-polarized current and induced spin polarization in non magnetic wells by their magnetic neighbors, among others.

In this work we analyze nonlinear electron spin dynamics of a n-doped dc voltage biased semiconductor II-VI multi-quantum well (MQW) having one or more of its wells doped with Mn. Even if normal contacts have been attached to this nanostructure, we show that spin polarized current can be obtained provided one well has been doped with magnetic impurities [2]. We have analyzed under which conditions the system exhibits static electric field domains and stationary current or moving domains and time-dependent oscillatory current. For our sample configuration, there are self-sustained current oscillations for nanostructures with three or more QWs. Moreover, current self-oscillations may appear or not depending on the spin splitting induced by both, the exchange interaction and the external magnetic field. We calculate the critical spin splitting needed to have self-oscillations. From our results we propose how to design a device which can behave as spin-polarized current oscillator.

Modeling of Spin-Transfer Torque in Magnetic Multilayers with Noncollinear Magnetizations.

H. Morise, S. Nakamura
Corp. R&D Ctr., Toshiba Corp., Kawasaki, Japan

The spin-transfer torque in magnetic multilayers[1, 2] can lead the magnetizations of nanomagnets to various types of dynamics such as excitaiton of spin waves[3], switching[4], and precessional motion[5]. These phenomena are expected to play key roles for realizing nanoscale spintronic devices such as MRAMs and microwave generators. The spin-transfer torque, whose origin is the interaction between the spin angular momentum of the conduction electrons and the local magnetic moments, can be estimated by the amount of the absorption of the transverse spin current in the magnetic layer. The transport of the transverse spin current across the interfaces[6] and that in the bulks[7, 8] have been investigated so far. However, the spin transport in the systems with many layers should be treated by taking both effects into consideration.

In the present work, we develop a theoretical modeling method to estimate the magnitude of the spin-transfer torque in a noncollinear magnetic multilayer based on such motivation. For the purpose, we employ a transfer-matrix technique which makes it easy to calculate the spin current in the system with many layers. We incorporate the chemical potential, the spin accumulation, the charge current, and the spin current into a location-dependent vector and relate the adjacent two vectors with the transfer matrix. With this method, we obtain the one-dimensional distribution of the spin accumulation and the spin current and as a result the magnetoresistance and the spin-transfer torque.

We calculate the spin-transfer torque in three kinds of multilayer structures by use of the above method. First, we consider the normal structure typified by Co/Cu/Co, which consists of a fixed layer and a free layer separated by a nonmagnetic spacer. Our special interest is on the roles of parameters characteristic to the noncollinear transport. Fig. 1 shows the critical switching current, which is inversely proportional to the spin-transfer torque, as a function of the transverse spin relaxation length l_j and those as functions of the normalized mixing conductances η^i and η^b . The result that the dependence on the mixing conductances is larger than that on the transverse spin relaxation length implies that the ballistic transport is ascendant over the diffusive transport in the system.

Second, we consider the synthetic antiferromagnet (SAF) structure, where the pinned layer consists of two magnetic sublayers antiferromagnetically coupled via a normal metal layer. A typical example of SAF is a multilayer composed of Co/Ru/Co. In this structure, the spin-transfer torque is reduced compared with that in the normal structure. However, the mechanism of the reduction has not been understood well yet. We consider two candidates for the mechanism, that is, the scattering of majority-spin electrons at the interface Co/Ru and the spin diffusion in the Ru layer. Fig. 2 shows the spin-transfer torque as a function of the relative angle between the magnetization of the pinned layer and that of the free layer. We find that short spin diffusion length of Ru layer is necessary to explain the P→AP switching. In other words, the diffusive effect is important for the spin transfer in this structure.

Third, we consider several types of the dual pinned layers (DPL) structure which includes an additional pinned layer in the opposite side of the first pinned layer from the free layer. Ref.[9] reported that some type of DPL structure produces much larger spin-transfer torque than that by the normal structure while another type of DPL structure does not. Our calculation on the enhancement factor agrees with this experimental result.

The dependence of the critical switching current divided by the thickness of the free layer on the transverse spin relaxation length and the normalized mixing conductances.

The spin torques for the SAF structure as functions of the relative angle between the magnetization of the pinned layer and that of the free layer. The spin asymmetry at the interface Co/Ru γ and the spin diffusion length of Ru layer l_{Ru} are changed.

FMR studies of single permalloy layers sandwiched by Al.

H. J. Hurdequint¹, N. Sergeeva¹, J. Ben Youssef²

1. Laboratoire de Physique des Solides, CNRS-Universite Paris-Sud, Orsay, France; 2.

Laboratoire de Magnetisme de Bretagne, CNRS-Universite de Bretagne-Ouest, Brest, France

Systematic investigations [1,2,3] of the spin resonance in magnetic films corresponding to purely metallic systems that we performed previously had revealed various remarkable phenomena that we associated to the specific nature of the interfacial coupling [2] between a ferromagnetic and a normal metal, which implies the *diffusion* of the microwave magnetization of the **conduction electrons** from one metal to the other. We have recently reported results of FMR studies of single permalloy (**Py**) layers sandwiched by **Ag**[4] and by **Au**[5]. The FMR results have been systematically compared to the ones obtained on 'control' Py layers sandwiched by Al₂O₃[6]. We report here the main results we have obtained in a detailed FMR investigation of three (**Py/Al**) films deposited by sputtering. We study (at X-band) the angular variation of the resonance spectrum (angle θ_H of the dc field with the film normal). The detected signal [5] is characterized by an A/B ratio which is a unique function of the signal 'phase'[1]. We highlight the most **remarkable** phenomena observed in the angular variation of the resonance spectrum.

SampleA: thick Py(40nm), sub/Al40/Py40/Al10). The linewidth ΔH presents (around $\theta = 10^\circ$) a very *pronounced* peak ($\Delta H_{\max} = 1.15$ kOe), much larger in amplitude than the maximum (0.15 kOe) observed and well understood [6] of a Py(43nm) control film.

SampleB: thin Py(12nm), sub/Al6/Py12/Al18). As displayed in Fig.1, the linewidth presents a peak at a specific orientation ($\theta_{\max} = 9.7^\circ$) around which a concomitant modification of the lineshape occurs. It is characterized by a rapid variation of A/B and hence of the signal *phase*.

SampleC: thin Py(3.5nm), sub/Al6/Py3.5/Al18). Continuously with the orientation θ the resonance spectrum is here composed of **two** lines. The main intense line corresponds to the **FMR** line of the Py layer. A second partially resolved peak is observed: in higher field in parallel geometry and in lower field in the perpendicular one. We identify this second peak to the **CESR** line of the conduction electron spin accumulation of the metallic film[5]. As displayed in Fig.2, a large variation of A/B is observed around the *crossing* orientation (27 deg), corresponding to a large (132 deg) variation of the signal phase when going from the parallel to the perpendicular geometry. This observation corresponds to the **first evidence** of the spin accumulation CESR signal in a single magnetic layer metallic film.

The ensemble of observed phenomena may be well understood and analyzed in terms of the theory of the signal (sketched briefly in ref[5]) we have developed to describe analytically the resonance spectrum observable in a **bimetallic** film (ferro/normal). Taking appropriate boundary conditions[7] at the metallic interface, the essential result obtained is that the resonance spectrum corresponds to the superposition of **two** sources of signal, associated respectively to the two eigenmodes (the 'current' and 'spin-diffusion' modes[8]) of propagation of the microwave magnetization in a metal. The crucial point is that these two sources of signal resonate at two distinct frequencies, the FMR frequency of the magnetic layer and the CESR frequency of the conduction electrons of the bimetallic film, respectively. Quite generally in a bimetallic film the two distinct H_{res} curves [H_{FMR} and H_{CESR}] will cross, the effect of the demagnetizing field being much weaker on the normal metal spin accumulation.

Spin filtering effect has been studied in ferromagnetic material (FM) / semiconductor (SC) hybrid structures and is recognised as a fundamental building block of spintronic devices. In such a simple structure, understanding both the transport characteristics and the scattering mechanisms of the spin-polarised carriers is prerequisite for developing more useful structures. In order to solve the conductivity mismatch problem [1], which occurs at the FM/SC interface, it has been referred that the tunnel contact between them could be appropriate for efficient spin injection/detection [2].

Here we present the results of the electron spin filtering effects across the tunnel barrier using the optical excitation of spin-polarised electrons in n- and p-doped GaAs. Al/NiFe(5nm)/AlOx(1.6nm)/GaAs structures were deposited by DC/RF sputtering in ultrahigh vacuum. As seen in regular TMR devices, the plasma oxidation method allows the formation of well defined alumina tunnel contacts with relatively high resistance, as evidenced by conventional IV characteristics. After film deposition, the active mesa was defined by conventional photolithography and electrically isolated from the adjoining region by subsequently depositing a 25 nm TaOx films. Conventional current-voltage measurements reveal that the devices show clear Schottky diode characteristics, and thus tunnelling transport is expected to be the dominant process for the filtering of spin-polarised electrons [3]. As Pierce and Meier had performed in 1976, the circularly polarised photons are possible to make spin-polarised carriers inside the GaAs, which will move to the interface adjacent to the FM detector via applied bias. The measured helicity-dependent photocurrent (HDPC) reveals that the degree of spin filtering depends on the magnetic alignment of the FM layer while the initial injection efficiency into the FM layer is determined by the alignment of the magnetic layer with respect to the photon helicity. Furthermore, the HDPC, corrected for MCD, shows the expected behaviour for a single FM/barrier structure. Since the external magnetic field was applied along the perpendicular to the plane, a polar geometry, one can observe the maximum spin filtering currents are varied and proportional to the degree of the magnetisation of the FM layer. In case of p-GaAs, the HDPC is purely dependent on the property of the tunnel barrier since the band bending at the interface is totally different with the one of n-doped SC. We discuss these results by considering spin dependent transmission across the interface, supported by the results of local electrical measurement.

Injection of spin polarized currents from thin ferromagnetic films into semiconductor light emitting diode (LED) structures has been used to study both the injection and transport of spin polarized electrons as part of a drive towards spintronic devices. In this study we look at LEDs with Fe films using both the Faraday and the oblique Hanle geometries. The magnetic injector films were 5 nm Fe, deposited by MBE on AlGaAs, which displayed the characteristic uniaxial anisotropies for this system [1]. Optical polarization spectra were detected in both geometries. These show a rich spectrum of peaks due to phonon-assisted recombination of light and heavy hole excitons (figure 1). The phonon replica peaks can be identified by their energy as LO, TA and LA phonon mediated showing that transport occurs in the X and L band minima in the semiconductor. The high electric field experienced by the electrons as they are injected through the Schottky barrier promotes electrons to these higher energy band minima. Transport in the X and L minima leads to rapid spin dephasing as shown by the theoretical work of Saikin et al [2]. This shows that optimisation of the semiconductor emitter for practical devices calls for in-depth understanding of the precise mechanisms of both transport and recombination in the entire structure. For example, in the case of the spectrum shown in figure 2, we observed a significantly larger optical polarization of the LO-phonon replica peak compared to that of the heavy hole exciton. This unexpected result shows that optimisation only for the exciton recombination wavelength does not lead in all structures to the highest polarization.

Furthermore, we have observed stronger phonon-assisted recombination and polarization in devices grown under continuous vacuum, than in samples transferred under an arsenic cap in air. This indicates that the clean interface may promote tunnelling to the X and L states, leading to a reduction of the net spin polarization of the injected current, therefore setting an upper limit for the efficiency of spin-injection through the Fe/GaAs interface separate to the models of Schmidt [3] and Rashba [4].

Introduction:

Organic spintronics is an exciting new research area, as it combines electron polarised spin transport with organic semiconductors. The long spin coherence length due to the weak spin orbit interaction in organic materials makes them potential candidates for spintronic devices. An organic spin-valve is a layered structure of two ferromagnetic electrodes with different coercive fields separated by a organic spacer layer^{1,2}. This research focuses on the further development of organic semiconductor spintronic devices consisting of magnetic/organic spacer/magnetic trilayers. The hole transporting polymers regio-regular^{3,4} and regio-random poly (3-hexylthiophene) were used as the spacer material; the choice was motivated by several factors, which included the highest occupied molecular orbital (HOMO) energy of P3HT (5.1eV) being close to the work function of the electrode material. Efficient carrier injection was therefore expected. Also P3HT has two different structures, with RR-P3HT being more conductive than RRa-P3HT. This is useful for the study of spin transport, as the spacer layer has the same chemical formula, but different electronic structure.

Experiment:

The organic spin-valves were $\text{Fe}_{50}\text{Co}_{50}/\text{RRa}(\text{RR})\text{-P3HT}/\text{Ni}_{81}\text{Fe}_{19}$ on glass substrates. The bottom electrode $\text{Fe}_{50}\text{Co}_{50}$ was dc sputtered at 25 kW/m^2 target power density at an Ar pressure of $7\mu\text{bar}$, to a thickness of 40 nm . The P3HT films were spin coated on top of $\text{Fe}_{50}\text{Co}_{50}$ electrode at around 1250 rpm , and then heated at 50°C for 10 min. The thickness, d , was varied by varying the toluene solution and ranged from 50 nm to 300 nm . Finally the top electrode $\text{Ni}_{81}\text{Fe}_{19}$, was thermally evaporated at a base pressure of $1 \times 10^{-7}\text{ mbar}$, to a thickness of 20 nm . Magnetoresistance (MR) measurements were carried out by applying a current perpendicular to the film plane with the field parallel to the film plane, at room temperature.

Results and Discussion:

The $\text{Fe}_{50}\text{Co}_{50}$ which has harder magnetic properties was chosen as the bottom electrode and the top electrode was $\text{Ni}_{81}\text{Fe}_{19}$ which has very soft magnetic properties. The magnetization loops of the FeCo and NiFe layers were measured using magneto-optic Kerr effect (MOKE) magnetometer (Fig. 1). Thus there is a large difference in the switching fields of the two electrodes. For the RRa-P3HT devices, we observe both anisotropic magnetoresistance (AMR) and spin MR for 50 nm (Fig. 2). We observed only the spin MR at room temperature in the RR-P3HT devices³, with spacer thicknesses less than 100 nm . Above 150 nm RR-P3HT thickness, the superposition of AMR with spin MR was observed. For the RRa-P3HT devices, a negative spin MR was measured, while a positive spin MR was measured in RR-P3HT devices. This will be discussed further in relation to the response of the polymer.

Spin electronics, or spintronics, is currently a very active field of research. Spin effects in devices and systems are dependent on the splitting of the electron current into spin sub-bands, or the spin polarization of the device. Devices improve in performance as spin polarization tends toward 100% or complete conduction through one spin sub-band. As such it is important to be able to accurately characterise the spin polarization accurately in materials. Ferromagnetic materials are of particular interest as these find wide applications in magnetoelectronic devices.

Previous research into the electron transport and magnetic properties of rare earth – transition metal Laves phase compound superlattices, in particular DyFe₂ and ErFe₂ layered with YFe₂, has demonstrated the formation of an exchange spring configuration [1,2]. Further studies resulted in the discovery of giant magnetoresistance (GMR) in these superlattices [3]. Laves phase rare earth – transition metal materials are excellent model systems in which to explore magnetic structures, switching and stability of exchange spring media.

Following on from these investigations, this digest focuses on the determination of the spin polarization of these Laves phase materials through point contact Andreev reflection (PCAR). It is hoped that characterisation of the spin polarization will lead to increased understanding of GMR in these Laves phase materials and superlattices.

Andreev reflection is a well studied effect discovered by A. Andreev [4]. At a metal-superconductor interface, conversion of normal current (single isolated electrons) to supercurrent (Cooper pairs) requires by conservation laws the creation of a hole travelling antiparallel to the electron current. Thus a second current channel is created and the conductance of the junction is doubled.

In ferromagnetic materials with a spin polarization this effect is suppressed, dependent on the degree to which the material is spin polarized. Research has been undertaken to determine the contact spin polarization P_c by PCAR in Ni, Fe, Co and alloys, including CrO₂ [5], FePt films [6] and the potential half-metal LaSrMnO_{3.5} [5,7].

A mechanical point contact technique was used as described elsewhere [8]. Differential conductance ($dI/dV = G(V)$) of the junction was detected using standard ac lock-in techniques at 2kHz frequency [9]. A point contact spectra for a 4000Å Laves phase DyFe₂ grown by molecular beam epitaxy is presented in figure 1. This spectra shows a clear peak in conductance below the superconducting gap of niobium at $\Delta = 1.5\text{meV}$.

Following the methodology of R J Soulen et al.[5] it is possible to extract a value for the contact spin polarization PC. Their method is based on a modification of the Blonder-Tinkham-Klapwijk (BTK) model of metallic-superconductor microconstrictions. The spin polarization may be extracted by decomposing the current through the point contact into two parts: a non-polarized part that obeys standard BTK theory and a polarized part that carries all the contact spin polarization PC. From this it follows that

$$G(V)/G_n = 2(1 - P_c)$$

Using this expression a value of $PC = 36.5 \pm 5\%$ is obtained for Laves phase DyFe₂.

It may also be noted that, by fitting the data to the modified BTK model, the value of Z , the interfacial scattering parameter, is low [10]. This may be seen from the absence of a dip at zero bias,

which increases in magnitude as Z increases. Low Z implies a good quality point contact and a small contact radius.

Conclusions

Through use of point contact Andreev reflection a value of $PC = 36.5 \pm 5\%$ has been determined. This value is close to that of iron, and closely resembles that of iron compounds such as NiFe published elsewhere⁵. It may be concluded that the spin polarization of these compounds is dominated by that of the Fe atoms, with the Dy atoms having a small modifying effect on the spin transport properties of the material.

Vapor phase synthesis of L1₀ FePt nanopowders and their magnetic properties.

J. Yu¹, D. Lee¹, B. Kim¹, T. Jang²

1. Department of Powder Materials Research, Korea Institute of Materials Science, Changwon, South Korea; 2. Dept. of Electronic Materials Engineering, Sunmoon University, Asan, South Korea

FePt nanoparticles are promising in magnetic materials for high density magnetic data storage media, since the FePt has a very high magnetocrystalline anisotropy, a high coercivity, and a high chemical stability [1].

In a bulk FePt, it needs to anneal at 1273 K to obtain the ordered tetragonal L1₀ structure from the disordered FCC structure through the order-disorder transformation. However, such annealing frequently leads to crystal growth and thereby concurring agglomeration of the separated nanoparticles. In order to avoid such agglomerations, we employed a new technique that allows preparation and annealing of FePt nanoparticles at the same time in the gaseous state prior to condensation. In this paper, therefore, we fabricated the L1₀-ordered FePt nanoparticles by the chemical vapor condensation (CVC) process and then investigated the microstructural characteristics and magnetic properties of the FePt nanoparticles.

The basic setup for CVC process is similar to that described in literature elsewhere [2]. To produce FePt nanoparticles, Ar carrier gas was fed through a heated evaporator (~230 °C) containing a solid precursor mixture of iron acetylacetonate and platinum acetylacetonate. The carrier gas entrained precursor vapor and passed through the heated furnace in which the precursor pyrolyzed and condensed into particles. The tubular furnace was uniformly heated at a temperature between 800 °C and 1000 °C and the FePt particles were attempted to synthesize at various mixing ratio of the precursors. Finally, the synthesized particles were collected from the chamber. And the characteristics of synthesized FePt nanopowders were analyzed by using TEM, XRD, XRD and VSM.

Chemical compositions of the FePt nanopowder synthesized at various mixing ratio of Fe and Pt precursors are summarized in Table 1. The Fe content in the synthesized powder increases monotonically with the increase of the amount of Fe precursor. Fe₅₀Pt₅₀ compound nanopowder is obtained only when the mixing ratio of Fe(acac.) and Pt(acac.) precursors is 2.5:1. This is simply due to more volatile property of Pt(acac.) than Fe(acac.).

Fig. 1 shows X-ray diffraction patterns of the FePt nanoparticles synthesized at various mixing ratio of the precursors. For the conditions of higher Pt contents (Fig. 1(a,b)), the peaks of PtO₂ are observed with typical cubic phase of FePt alloy. This is due to the excess amount of Pt metal vapor decomposed from Pt(acac.), which is left over after the formation of FePt and then oxidized. On the other hand, as shown in Fig. 1(c), the diffraction pattern of ordered L1₀ FePt phase is obtained at a higher Fe precursor mixing condition. It shows the (001) and (110) superlattice lines, indicating that a significant degree of L1₀ ordering phase, without any post annealing process. This result is confirmed by the selected area diffraction (SAD) result.

Fig. 2 shows TEM micrographs of the FePt nanoparticles synthesized at different reaction temperatures. The particles have spherical shapes and slightly agglomerate each other, yielding the average particle size of ~ 5 nm at 800 °C, ~ 7 nm at 900 °C, and ~ 10 nm at 1000 °C, respectively. It indicates that the particle size increases with the increase of reaction temperature, mainly due to the accelerated sintering effect at higher temperature. The collision of condensed nanoparticles occurs more actively at higher temperature, leading to easy growth and agglomeration of the nanoparticles as can be seen in Fig. 2(c).

A room temperature magnetization curves not exhibit superparamagnetism, unlike the particles of Sun et al. [1]. However, the coercivity of the powder in an isotropic state has quite lower value (~ 570 Oe). The details of magnetic properties will be discussed with the morphological and microstructural aspects of synthesized FePt nanopowders.

Two easy axes effect on nanosized spherical particles for advanced tape storage.

Y. Wang, J. Zhu

Electrical and Computer Engineering, Carnegie Mellon University, Pittsburgh, PA

INTRODUCTION

For advanced tape media, nanosized composite advanced particles (NanoCAP) [1], developed with spherical shape and high coercivity, have produced potential for spherical particles to replace their acicular counterparts in high density tape recording due to smaller size, higher packing fraction and stronger anisotropy. It was also demonstrated [2] that spherical particles should yield superior recording performance with an appropriate writer. The measurement of the hysteresis loop indicates that the particles have uniaxial crystalline anisotropy. However, it is extremely difficult to produce perfectly spherical particles, which introduces significant parasitic shape anisotropy. The combined effect of the two anisotropies is studied by micromagnetic modeling. Possible improvements are also discussed.

MODELING AND PARAMETERS

A micromagnetic model is developed to simulate spherical particles with a core-shell structure. Landau-Lifshitz-Gilbert equation is employed to fully study 3D micromagnetic behavior. The particle locations are random and the packing fraction can be up to 45%.

The two easy axes of the particle are illustrated in Fig 1. The diameter of the particle and its inner magnetic core is 17nm and 10nm, respectively. The particle aspect ratio is set to 1.5 estimated from the TEM picture in [1]. Damping constant is assumed to be 0.1 in the simulation. Packing fraction of the tape is usually around 40%. Other parameters will be discussed later.

RESULTS AND DISCUSSIONS

Coexisting with uniaxial crystalline anisotropy, the parasitic shape anisotropy degrades the hysteresis loop show in Fig 2(a). In the simulation, the easy axes of both crystalline and shape anisotropies are totally random in 3D space. It is important to note that the random angle θ between the two easy axes causes the more incoherent switching behavior among particles.

Fitting with experimental data is performed in Fig 2(b). Excellent agreement with experimental data is observed. Magnetization is obtained at 2500emu/cc and crystalline anisotropy constant 10^7 erg/cc. It indicates that the material exhibits high saturation magnetization and anisotropy, which is coherent with [1]. For the rest of the results presented here, these parameters are used for all calculations.

Recording simulations are also performed shown in Fig 3. Two transitions are written at the linear density of 150 KFCI. With the increase of aspect ratio from 1.0 to 1.5, the recording transition profile continues to suffer from the parasitic shape anisotropy. A deep gap field of 7000 Oe and gap width 200 nm is assumed in the simulation. The direction of effective easy axes of the two anisotropies is set to have a standard deviation of 15 degrees with respect to the downtrack direction. Transition noise is boosted as well which will be included in full paper.

Further improvements are also feasible. One possible improvement is to align the particle long axes to the vicinity of downtrack direction. This may help the effective easy axes to align closer to the desired direction. The other option is to reduce the saturation magnetization of the particle. Since the strength of shape anisotropy is proportional to the square of magnetization, the negative influence will be greatly reduced. And high packing fraction of spherical particles ensures sufficient strength of the readback signal. More details will be presented in full paper.

Synthesis and self-assembly of phase-, size- and shape-controlled $L1_0$ -FePt nanorods by a modified polyol process.

L. C. Varanda¹, M. Jafelicci Jr.²

1. *Físico-Química, Instituto de Química de São Carlos - USP, São Carlos, Brazil*; 2. *Físico-Química, Instituto de Química de Araraquara - UNESP, Araraquara, Brazil*

FePt nanoparticles with controlled size, shape, chemical composition and magnetic alignment has become an important goal in developing nanocrystal arrays for applications in information storage, high performance permanent-magnets, biomedicine and catalysis.^{1,2} These alloys are chemically stable and their magnetic properties tuned by controlling the Fe/Pt atomic ratio and by nanocrystal size. Most of previous work has focused on the synthesis of spherical FePt nanocrystals, mainly based in the polyol (volatile and toxic $\text{Fe}(\text{CO})_5$ uses)³ or polyol-derivate (using $\text{Fe}(\text{acac})_3$)^{1,4,5} processes. Despite these synthetic progresses, aligning these spherical nanoparticles magnetically has constantly been a problem for practical applications, and the magnetic easy axes of the assembled nanocrystals are randomly oriented in 3D.^{1,2} This controlled alignment is essential for the fabrication of single-particle recording media with ultrahigh density, magnetic nanocomposites with maximum energy product, and magnetotransport devices². Thus, 1D FePt nanorods (NRs) or nanowires are more interesting because they are expected to have magnetic and structural anisotropy with unique magnetic properties. To this end, few efforts were recently made on the synthesis of Pt-based (NRs) and generally using the problematic $\text{Fe}(\text{CO})_5$ compound.^{6,7} Previous reported procedure³ was modified in this work and the synthesis and self-assembly of FePt (NRs) with controlled shape, size and composition in the chemically ordered fct phase using a modified polyol process were reported. Typical synthesis of $L1_0$ - $\text{Fe}_{55}\text{Pt}_{45}$ NRs following: in a three-necked round-bottom flask under gentle nitrogen flow and stirring, $\text{Pt}(\text{acac})_2$ (0.5 mmol), oleylamine (OAm) and octadecene (OD) -OAm/OD of 2:1 (v/v)- and total volume of 20 mL were mixed and heated at 60 °C. 1,2-hexadecanediol (1.5 mmol) and $\text{Fe}(\text{acac})_3$ (0.61 mmol) were added into the solution and the temperature slowly increased at 120°C, which was kept for 30 min. The temperature was then slowly raised to 180°C. After 3 hours, the suspension was cooled down to room temperature and the resulting NRs were separated by adding hexane and ethanol and centrifuging. NRs were self-assembled by droplet a dispersion of the particle in a 50:50 mixture of hexane/octane and slowly evaporated at room temperature. Length and composition of the NRs can be realized by tuning the volume ratio of OAm/OD and the Fe/Pt molar ratio, respectively. TEM results (Fig 1a-b) indicate that synthesized NRs are a monodisperse system with 60 ± 5 nm in length and diameter of 2-3 nm and the controlled evaporation of the 60-nm $\text{Fe}_{55}\text{Pt}_{45}$ NRs in hexane/octane dispersion led to an $\text{Fe}_{55}\text{Pt}_{45}$ NR array with the NRs parallel to each other (Fig. 1b). According to the HRTEM image (Fig 1c) the NRs present a single nanocrystals structure and the lattice fringes are oriented $\sim 90^\circ$ from the rod-growth direction with interplanar distance found to be 0.284 nm, closed to the lattice spacing of the (110) planes (0.276 nm) in the fct ($L1_0$) FePt structure. This result suggest that the [001] direction is parallel to the rod-growth direction and that the fct phase was directly obtained during the synthesis, in contrast with the previews reported synthesis of the FePt NRs where the as-synthesized particles present the fcc phase.^{2,6,7} The presence of the fct phase was confirmed by the XRD patterns (Fig 1d) and agrees with the direct fct structure related for spherical FePt nanoparticles⁵ when the reaction kinetic was enhanced by using the slow heating rate, low temperature and the gentle stirring. The fast reaction kinetic favor the size decrease, but also favor the unstable fcc phase, in contrast with the condition used in this work, which the reaction rate is slow and the most stable phase (fct) was realized. Therefore, the XRD pattern of the assembly

shows a stronger (001) peak relating to the (111) peak, indicating a partial structural alignment with the (001) planes parallel to the substrate. In-plane magnetic hysteresis loop of the assembly shows the better squareness with the coercivity reaching 10 kOe (Fig 1e).

Introduction

Sputtered tape media is a promising candidate for advanced storage tape with over 10 TB capacity per cartridge. By facing targets sputtering (FTS)[1], a nanometer-sized granular CoPtCr-SiO₂ film for longitudinal recording can be formed on a thin plastic substrate at room temperature with no damage[2]. In this paper, preparation of CoPtCr-SiO₂ film by FTS on a moving substrate is demonstrated, and moving speed effect on playback performance and microstructure is investigated.

Experimental

CoPtCr-SiO₂ granular magnetic film for longitudinal recording was formed by a multi-gun FTS system with a moving substrate apparatus at room temperature without cooling. Cross-sectional structure of sputtered media is C(5 nm)/CoPtCr-SiO₂ (20nm)/Ru (20nm)/Aramid substrate(4.5 μ m). Argon pressure for sputtering for magnetic layer was 0.8 Pa. Microstructure was observed by 200 kV transmission electron microscopy (TEM). Playback performance was evaluated by a drum tester with anisotropic magnetoresistive (AMR) reader (track width=5.5 μ m, shield-to-shield length=170nm)/writer (track width=12 μ m, gap length=170nm) heads at tape speed of 3 m/s. Medium noise was measured in a range of 0 to 20 MHz.

Results and discussion

Two samples at different moving speed of substrate were named as sample L (slow moving speed, 5.8 cm/min) and sample H (high moving speed, 100 cm/min). In-plane coercivity and squareness were measured as 308.8 kA/m and 0.74 for sample L, 318.3 kA/m and 0.69 for sample H, by a vibrating sample magnetometer. XRD measurements showed epitaxial growth of *hcp*-CoPt-Cr(100)/*hcp*-Ru(100) planes. Figure 1 shows in-plane TEM images of sample L and H, which have similar microstructure of clear boundary and grains with uniform sizes. Vertical direction in Fig. 1 corresponds to moving direction of substrate during sputtering. Grain shapes and sizes of sample L and H are independent on the moving direction and speed. Average grain sizes were estimated at 8.0 nm for sample L and 7.8 nm for sample H. Segregations of Cr and Si to boundary regions of both samples were confirmed by point energy dispersive X-ray spectroscopy (EDS).

Cross-sectional TEM image of sample H are shown in Fig. 2, which indicates that straight columnar grains were grown and unaffected by the moving direction. So, it is concluded that moving speed of substrate does not affect the microstructure of the media by FTS.

Figure 3 shows the signal-to-noise ratio (SNR) dependence on linear recording density for both samples, measured by a drum tester. In Fig. 3, MP indicates commercial particulate tape media as a reference with coercivity of 214 kA/m and 0.5 Gb/in² areal density. SNR values for sample L and H are almost same in all densities, and over 8 dB higher from that of MP as well. PW50s, a pulse width of an isolated signal, for MP, sample L, and H were measured 361, 236, and 235 nm, respectively. Shorter PW50s than that of MP by 125 nm indicate resolution of sputtered tape by FTS on moving base film is better than that of particulate media. From these comparisons on playback performance and microstructure of sputtered tape media by FTS on moving substrate at slow and high

moving speed, it is suggested that FTS process is suitable for efficient mass production of granular media.

In addition, we have successfully achieved deposition even on moving PEN and PET film, which are less thermally-resistant than Aramid, thanks to damage-free sputtering by FTS.

Conclusion

Moving speed of plastic substrate didn't affect on microstructure and playback performance of nanometer-sized granular media made by FTS. These results show that FTS process has great capability for mass-production of sputtered tape media with high throughput.

Abstract

The possibility of realizing the linear magnetic recording system over 15Gbit/in² recording density has shown in our test with our newly developed MP (metal particulate) tape using 35 nm size fine metal particles and GMR head for HDD (hard disk drive).

Introduction

In order to obtain a high recording density, advanced magnetic recording media for tape systems using GMR head have been investigated. 1) 2) 3) It is necessary to use very low noise media to realize high recording density. For the particulate magnetic recording media, very fine particles, uniform dispersion of the particles and an extremely thin and smooth magnetic layer are required. We have reported a recording density of 3 Gbit/inch² with MP tape using 45 nm size fine metal particles and GMR head. This paper reports the experimental results of the developed particulate tape using 35 nm size fine metal particles, which shows the capability of more than 15 Gbits/inch² recording density with a narrow track GMR head.

Measurement & results

An MP tape sample using 35 nm size fine metal particles with the smooth surface and the thin magnetic layer was prepared. Table1 shows the tape structure and the characteristics of this sample. Abrasivity and electronic resistance of this tape were optimized for GMR head application. In order to prevent ESD, we adjusted the electronic resistance of this sample to a few mega ohm/sq. The electromagnetic property of this sample was measured by a drum tester with a MIG write head and a narrow track GMR read head (track width: 0.14 μ m) for HDD. Table 2 shows the measurement condition and the head property of this test. Under this condition with optimum write current, DSNR (Digital Signal to Noise Ratio) of this MP sample was calculated using eye diagram of the output signal of the pseudo-random pattern at 30MHz data clock.(minimum recording wave length 1T: 0.23 μ m). The DSNR of this MP sample was 18.7 dB when we used PR4 channel. Fig.1 shows the eye diagram of the test result. No ESD of GMR head were occurred during this test.

According to the test results with the assumption that 18 dB of DSNR meets the system requirement, this MP sample has enough SNR at this test recording density, which is 39.5G physical bit per inch² (218 kfc_i and 181 ktp_i). Considering that the read track width is narrower (about half) than the track pitch for linear tape systems and the coding efficiency, this test conditions correspond to more than 15 Gbit/inch² recording density for linear tape systems.

Our newly developed MP tape sample with 35 nm size fine metal particles has the capability for realizing the linear tape system of more than 15 Gbit/inch² recording density with a narrow track GMR head.

Investigation of thermal de-magnetization effects in data recorded on barium ferrite recording media.

M. L. Watson, T. W. Feebeck, R. A. Beard, S. M. Kientz
Storage Group, Sun Microsystems, Louisville, CO

It is very evident that, to remain competitive with alternative storage technologies, future tape based storage systems must have very significantly increased data rates and cartridge capacities. To achieve single cartridge capacities of many terabytes the volume of the recorded bits must be reduced to less than $10 \times 10^6 \text{ nm}^3$. Realizing viable recording channel signal to noise ratios (SNR) with these bit sizes requires that the number of magnetic particles per bit will have to be at least maintained compared with today's media. This will require particles with dimensions as small as 10 nm – 20 nm (with corresponding particle volumes of 1000 – 3000 nm^3 respectively).

Recording media fabricated using barium ferrite particles has been investigated for a number of years. Very recently advanced media of this composition has been demonstrated to have excellent recording performance with ultra-narrow read widths and at high linear densities [1]. The barium ferrite particles have a diameter of ~ 21 nm and a hexagonal platelet shape and can be manufactured to have a relatively high intrinsic magnetic coercivity due to their high crystalline magnetic anisotropy. However the reduction in particle size could, potentially, affect the archival storage capability of this type of media due to thermal demagnetization [2]. This paper reports the results of experimental studies undertaken to determine if such effects are present in this type of media.

To determine the thermal stability of the media time dependent coercivity measurements were performed, using a standard vibrating sample magnetometer (vsm), and a previously well described technique [3]. Several different media samples were investigated and, due to the inherently low moment of these samples, the vsm measurements were made using a 6.27-mm diameter disk laminated from ten sections of each media sample. Up to 12 different applied fields were used for each measurement and in each case the data could be fitted extremely well using a logarithmic trend-line. The estimated time to reduce the magnetic moment to zero and the applied field (H_{cr}) for each data set was then used as an input to the equation [4]

$$H_{cr} = H_0 \{ 1 - [(K_u V / k_b T) \ln(f_0 t / \ln(2))]^n \}$$

and the values of $K_u V / k_b T$ and H_0 were obtained using a Matlab non-linear optimization routine to fit this equation to the data. A typical data set, and the fit to the data, is shown in Fig. 1. From these measurements a value of $K_u V / k_b T \approx 100$ is obtained, indicating acceptable archival thermal stability for this media.

To determine if data recorded in this media is thermally stable, tapes were pre-written with random encoded data at various linear densities. The tapes were then baked alternately at 37 C, 49 C and 59 C for times up to 10^6 seconds and read back after each bake cycle using a nominally 1.0 μm read width GMR read head. The data was captured and processed using a sophisticated recording channel model which performs read equalization, timing recovery and Viterbi channel detection. The model has been found to very effectively replicate actual channels and recording systems and outputs several critical recording channel performance parameters, including the SNR of the sampled and equalized signal at the channel detector (D-SNR). Fig. 2 shows the D-SNR of tracks written at several linear densities immediately after writing and after baking multiple times. As can be seen there is no statistical difference between the two data sets, indicating that this media does indeed have good archival thermal stability. As can also be seen from Fig. 2, the D-SNR is very acceptable indeed (> 17 dB) at linear densities up to at least 360 kbp, enabling very practicable bit error rates using advanced decoder and ECC systems.

The authors very gratefully acknowledge FUJIFILM Corporation for providing the media samples used in this investigation.

Influence of the capping molecule on the magnetic behavior of thiol capped gold nanoparticles.

P. Crespo¹, E. Guerrero², M. Muñoz-Márquez², A. Hernando¹, A. Fernández²

1. Instituto de Magnetismo Aplicado, Universidad Complutense de Madrid, P.O. Box 28230 Las Rozas, Madrid, Spain; 2. Instituto de Ciencia de Materiales de Sevilla, CSIC-US, Av. Américo Vespucio 49, 41092-Sevilla, Spain

Metallic nanoparticles (NPs) have been extensively studied, since they exhibit novel electronic, optical and magnetic properties. In particular, the experimental observation of ferromagnetism in gold NPs (with sizes below 2.5 nm) up to room temperature after appropriate functionalization of the surface is promoting a huge number of studies focused on the mechanisms that could account for ferromagnetic-like behavior. Alkanethiol-capped gold NPs [1] have shown a permanent magnetism which is currently not understood. Recently, Hernando et al. [2] proposed spin-orbit coupling as the origin of orbital ferromagnetism in these systems.

From the experimental results obtained up to date, it is clear that the apparition of the magnetic behavior, in spite of the diamagnetism exhibited by bulk gold, is closely related with the interaction between the surface of the gold NPs and the protective molecule. In this work, gold nanoparticles (NPs) have been stabilized with a variety of thiol-containing molecules in order to change their chemical and physical properties. It is shown that NPs capped with alkanethiol chains have a marked ferromagnetic behavior which might be also dependent on the chain length. Moreover, the structural and magnetic characterization performed on the polymer-like Au(I) phase, which is formed as a precursor during the synthesis of the thiol-capped gold NPs, clearly indicates that the appearance of a ferromagnetic-like behavior is not only associated with the charge transfer that takes place upon Au-thiol group bonding but also with the formation of a metallic nanostructure, being necessary the simultaneous coexistence of Au-Au and Au-S bonds[3].

Moreover, as will be shown in this work, the geometry of the molecule also plays an important role on the magnetic behavior. Besides using alkane chains with different lengths as capping agents, gold nanoparticles stabilized with a thiol-containing biomolecule (tiopronin) have been also synthesized. While alkane chains are linear molecules and have a high tendency for self assembly, tiopronin molecules exhibit non-linear geometry. In both cases, the organic molecules are linked to the sulphur atom that bonds to the nanoparticle surface. X-ray absorption spectra (XAS) studies, magnetic characterization and surface plasmon resonance studies have been carried out for these two types of thiol-capped gold nanoparticles (NPs) which have similar size. In addition, Au NPs capped with tetraoctyl ammonium bromide have also been included in the investigation since such capping molecules weakly interact with the gold surface: this system will be used as a model for standalone-Au NP.

Regarding the magnetization, dodecanethiol-capped NPs have a ferromagnetic-like behavior, while the NPs capped with tiopronin exhibit a paramagnetic behavior and tetraalkylammonium-protected NPs are diamagnetic (as correspond to bulk gold) across the studied temperature, see figure 1. These differences indicate that the modification of the surface electronic structure of the Au NPs depends on the geometry and the self-assembling capabilities of the capping molecules. Moreover, the lack of self assembling capabilities could avoid the appearance of orbital momenta in the conduction electrons of the nanoparticle, this mechanism has been proposed, along with high values of spin-orbit at gold surfaces, as to be responsible for the high local anisotropy field that blocks the magnetic moment.

In addition to the magnetic behaviour, regarding the plasmon resonance, it can be said that it is non-existent for tiopronin-capped NPs, whereas a trace of such a feature is observed for NPs covered with dodecanethiol molecules and, a bulk-like feature is measured for NPs capped with tetraalkylammonium salts. These results are additional data which indicate that optical, electrical and magnetic properties of gold nanoparticles are related to several factors including charge transfer, geometry of the capping molecule and, in general, size and surface structure effects.

XMCD study of thiol capped Au nanoparticles.

V. Bouzas¹, M. Garcia¹, P. Andrea⁴, D. Haskel², G. Ruggeri⁴, C. de Julian Fernandez³

It is well known that the physical properties of the materials are modified when the size is reduced to the nanoscale. An example of this nanoscale induced magnetism is the appearance of ferromagnetic-like behaviour in thiol capped Au nanoparticles (NPs) [1]. The bond between the sulphur atoms at the end of the thiol chain and the Au atoms at the NPs surface induces a charge transfer (as measured by XANES) from the Au to the S atom [2]. This transfer creates an open 5d electronic configuration in the surface of Au NPs needed for magnetism. While the effect has been reproduced in different samples and by different groups independently, the origin of this magnetism is still under discussion. XMCD can be a key tool to elucidate the origin of this magnetism due to its unique features as element sensitivity, the possibility to determine the orbital holding the magnetic moment and to separate orbital and spin contribution to the magnetization. The aim of this work is to study the origin of the magnetic ordering in thiol capped Au NPs by XMCD measurements.

Dodecanethiol-capped Au NPs were prepared as described in the literature following the bottom-up approach [3]. Briefly, polymeric Au nanocomposites were prepared by casting a solution of 4 wt. % of Au NPs and ultra high molecular weight polyethylene (UHMWPE) in p-xylene at 125 °C, and recovering the film after solvent evaporation at room temperature.

Bright-field transmission electron microscopy (TEM) shows mostly spherical shaped particles with a mean size of about 3-4 nm (Figure 1). Au NPs are well dispersed inside the polymer matrix thanks to the dodecanethiol protecting layer that prevented particle aggregation during film preparation at high temperature.

SQUID measurements previously reported [4] showed that the sample exhibit a diamagnetic behavior with a ferromagnetic-like contribution. This ferromagnetic-like contribution is thermally independent in the 5-300 K range, and has a saturation value of 0.05 emu/g(Au), being saturated for a 0.5 T field.

XANES and XMCD measurements were performed at the L3 edge of Au. Figure 2 presents the results after 66 scans (33 with field $H=+4$ T and other 33 with $H=-4$ T, measured reversing the field each 3 spectra). Since field-reversal is equivalent to helicity switching measurements with opposite field direction can be combined to remove any spurious signal of non-magnetic origin. No XMCD signal was found in the sample, with resolution of 5×10^{-5} . Therefore if the XMCD signal exists, its value is below this limit.

Previous XMCD experiments on Co/Au multilayers [5] and Au NPs protected with polyallil amine hydrochloride [6] shown a ratio $0.23 \text{ XMCD}/(\text{emu/gAu})$ between the SQUID and XMCD signals. In our samples the MS value (0.06 emu/gAu) correspond to $2.11 \times 10^{-3} \mu_B/\text{atom Au}$. Based on the ratios from the previously mentioned works, if this magnetization were localized in the 5d orbital of the Au atoms, the XMCD signal should be 4.7×10^{-4} , about one order of magnitude larger than the sensitivity of our experiment. Therefore, our results demonstrate that the magnetization of thiol capped Au NPs is not fully localized in the 5d orbital of Au atoms.

The present work reports the formation of Ni nanostructures, their growth and saturation to form oxides by using ion implantation and subsequent thermal treatment in air at 600°C. Quartz (SiO₂) matrix was implanted with 100 keV Ni⁺ ion beams to doses in the range 5×10^{15} – 2×10^{17} ions/cm². The formation of Ni nanoclusters were observed by high resolution X-ray diffraction (HRXRD), UV-visible optical spectroscopy, dc magnetization, AFM/MFM and X-ray absorption spectroscopy (XAS). The cluster size distribution is narrow with an average size of $\sim 25 \pm 0.5$ nm for the implanted sample at a dose of 1×10^{16} ions/cm², but increases with implantation dose. Optical absorption spectra also show a clear signature of a surface plasmon resonance (SPR) peak at around 388 nm in accordance with the theoretical Mie's spectra. Temperature dependent zero-field cooled and field-cooled magnetization measurements clearly indicate a superparamagnetic behavior, which is properly analyzed considering the size distribution of the magnetic nanostructures. The results show that the magnetic properties of the nanoparticles can be controlled by the implantation dose. A detailed investigation of the local structure using Ni K-edge XANES/EXAFS suggests that the size of the Ni nanostructures is altered with implantation dose, reaching saturation in the form of oxides/silicates of Ni at a dose of 2×10^{17} ions/cm².

In the ZFC curves for 1×10^{16} ions/cm² (Fig.1), a characteristic superparamagnetic (SPM) peak confirms the nanoscale nature of Ni clusters. Also, the separation of ZFC and FC curves at a certain irreversibility T_{IRR} temperature is one of the characteristic features of superparamagnetism (SPM). We have seen that there is a sharp maximum in ZFC magnetization curve at about 18 K, which indicates the mean blocking temperature of the nanoclusters of Ni. However, with further increase in the fluence value the ZFC curves becomes broader. The broadening in the ZFC magnetization peak may be due to various reasons such as (i) broad particle size distribution, (ii) magnetic dipole-dipole interaction and (iii) some oxide formation. However, the reason (iii) can be ruled out as there is no formation of Ni oxide at a dose of 5×10^{16} ions/cm² in agreement with the XRD results. We have found that the magnitude of the magnetization also did not vary linearly with the increase of Ni ions in the system, which is less than the calculated value, may be due to the dipole-dipole interaction or some oxide formation (only at dose greater than 5×10^{16} ions/cm²).

In order to understand the local structure of Ni nanostructures, we have performed the near edge X-ray absorption fine structure at O K-edge and Ni L_{3,2}-edge of all samples along with NiO nanoparticles. Figure 2 shows the normalized spectra of O K-edge all the samples along with SiO₂ and NiO nanoparticles. NiO nanoparticles show two major structures at 531.58 eV and 537.36 eV with broad hump at higher energy range. These two structures may be due to the O 2p weight in states of predominantly Ni 3d character¹⁻². In the case of SiO₂, one structure at 535.42 eV and broad hump at higher energy are observed. In the implanted samples up to the dose value 1×10^{17} ions/cm²

the O K-edge NEXAFS show spectra that are almost similar to the ones of SiO₂, which indicates that is no oxidation of Ni nanostructure taking place, but at the dose of 2×10^{17} ions/cm² the spectrum is well matched with the spectra of NiO nanoparticles. Such results also support our above mentioned results. The results of Ni K-edge suggested that the size of the Ni nanoparticles changes with the dose, reaching saturation in the form of NiO nanoscopic structure at a dose of 2×10^{17} ions/cm².

Nowadays, fine magnetic particles [1] are routinely used in many technological applications, such as magnetic recording and non-linear optics, and they are considered promising materials for various biomedical applications. Consequently, the study of their magnetic properties have attracted many efforts along the last decades, in particular because considerable deviations from bulk behavior have been widely reported for particle sizes below about 100 nanometers [3]. In particular, magnetic properties at the particle surface are governed by the breaking of the lattice symmetry associated with several chemical and physical effects leading to a site-specific surface energy, usually taken as a local uniaxial magnetic anisotropy normal to the surface. In the nanometer range of sizes, the contribution of the surface anisotropy to the total effective anisotropy of the particle may be larger than that of the core, which highly increases the characteristic switching time of the particle magnetization as a result of the increase of the effective energy barrier. Here, we study the magnetic anisotropy barrier distribution in a magnetite Fe_3O_4 nanoparticles in a colloidal suspension, in the framework of the $T\ln(t/\tau_0)$ scaling method of the time-dependent thermo-remnant magnetization data. The particles are synthesized by the high-temperature decomposition of an organic Fe precursor in the presence of a surfactant (oleic acid molecules covalently bonded to the NP surface) [2]. Transmission electron microscope images reveal a narrow size distribution with mean diameter $\langle d \rangle = 5$ nm. The Zero Field Cooling–Field Cooling (ZFC–FC) curves at 50 Oe show superparamagnetic behaviour down to ca. 50 K and a maximum in the ZFC curve at 15 K, while the irreversibility between the ZFC and FC curves confirms that our sample is a colloid of non-interacting particles. These two facts make the system suitable for a study on individual particle properties. Thermo-remnance experiments and $T\ln(t/\tau_0)$ scaling enable to obtain the effective distribution of anisotropy energy barriers [4]. We have developed an analytical model to account for the surface contribution to that effective energy barrier distribution. Furthermore, assuming a bulk anisotropy constant for the volume of the particle, $K_v = 1.3 \times 10^5$ erg/cm³, we obtain analytically the surface anisotropy constant, $K_s = 2.9 \times 10^{-2}$ erg/cm². Besides, the K_s value obtained applying a Néé-type relaxation mode to both the in-phase and out-of-phase components of the ac susceptibility gives is in excellent agreement with the value obtained from the scaling. Summarizing, thermo-remnant magnetization data and the $T\ln(t/\tau_0)$ scaling method enable to analytically account for the surface anisotropy contribution of an ensemble of nanoparticles in a colloidal suspension in absence of interparticle interactions.

Nanotechnology has spurred researcher efforts to design and produce nanoscale materials for incorporation into devices. Magnetic nanocomposites are an important class of functional materials, possessing unique magnetic properties associated to their reduced size (below 100 nm) with potential for use in devices with reduced dimensions. In special, due to high saturation magnetization, high magnetic susceptibility and low toxicity, ferrimagnetic iron oxide nanoparticles are promising candidates for applications as contrast agents in magnetic resonance imaging [1], material platform for DNA extraction [2] and gene and drug delivery [3]. On the other hand, as far as the size and size-dispersity control are concerned, the tendency of isolated magnetic nanostructures to aggregate (which is driven by particle-particle interaction and/or reduction in energy associated to the high surface-to-volume ratio) into bigger clusters during the synthesis process, has represented a critical obstacle. A general approach to overcome this obstacle and tailor particle surface properties for technological applications can be achieved by surface-coating or encapsulation [4]. Magnetic polymer-based spheres (micron-sized and nanosized) have been considered as an important material in the biotechnology industry [5]. In particular, mesoporous polymeric templates could be produced as micron-sized spheres allowing in-situ chemical synthesis of nanosized ferrite particles with adjustable magnetic properties and mass density [6]. The fine-tuning of physical parameters such as the net magnetic moment and composite density can be realized using chemical methods.

In this study, stable and size-controllable magnetite (Fe_3O_4) nanoparticles were prepared using mesoporous sulfonated styrene-divinylbenzene (Sty-DVB) copolymer as the hosting template. Several cycles (N) of chemical synthesis were used in order to increase the amount of encapsulated iron oxide and in order to tune the magnetic nanoparticle size [7]. The nanoparticle size distribution of the hosted magnetic phase was determined by Transmission (TEM) and Scanning (SEM) Electron Microscopies. Figure 1 shows a typical SEM of micron-sized magnetic nanocomposite hosting magnetite nanoparticles. X-ray diffraction (XRD) was used to determine the magnetite phase (see Fig. 2) and also to estimate the particle size.

The magnetic characterization of the samples was carried out using DC and AC magnetic measurements in a broad range of temperatures (4-300K). The estimated effective anisotropy constant (K_{eff}) is slightly above the values reported for bulk magnetite which suggests that the effect of other kind of anisotropy (surface or exchange) has less influence in the magnetic behavior of our magnetite nanoparticles. From DC magnetic isotherms, obtained by applying external magnetic fields up to 5T, it was observed higher coercive fields values for samples obtained with minimal chemical cycles (N). The hyperfine properties of the nanoparticles were investigated by Mössbauer Spectroscopy (MS). 77K and room temperature MS data reveal hyperfine parameters with a strong dependence on the number of chemical cycles (N).

Magnetite Nanoparticles With No Surface Spin Canting.

A. Roca¹, D. Niznansky², M. González-Fernández¹, M. Morales¹, C. Serna¹

1. Instituto de Ciencia de Materiales de Madrid (CSIC), Madrid, Spain; 2. Department of Inorganic Chemistry, Charles University, Prague, Czech Republic

When magnetic nanoparticles sizes cross the multidomain-monodomain limit, surface and finite size effects become more important and cause the appearance of many interesting physical properties [1]. In particular, spin canting at the surface have been observed to take place and to be the responsible for the reduction in saturation magnetisation and the increase in anisotropy and therefore in coercivity of the nanoparticles at low temperature[2].

New methods have been developed recently for the preparation of high quality nanoparticles in terms of size and shape monodispersity and high crystal order. That is the thermal decomposition of iron organic precursors in organic media and in the presence of oleic acid. This method have been used in this work for the preparation of magnetite nanoparticles of 6 nm in diameter and the surface spin canting effect has been analysed by different techniques, including magnetic measurements and Mössbauer spectroscopy at low temperature and in the presence of a magnetic field. Mössbauer is a powerful tool for studying structural, physical and magnetic properties and the best for iron oxide nanoparticles [3]. Magnetite nanoparticles of similar size prepared by coprecipitation and subsequently coated with a thin silica layer to reduce dipolar interactions and prevent from aggregation, have been used for comparison.

TEM images show that iron oxide nanoparticles synthesized by thermal decomposition are more uniform than those prepared from coprecipitation[4]. Magnetic measurements show superparamagnetic behaviour for the three samples at room temperature and higher saturation magnetization for the nanoparticles synthesized by thermal decomposition. Also, it has been shown that these nanoparticles saturate its magnetization at lower applied magnetic field than the coprecipitation ones. At low temperatures, the three samples show ferromagnetic behaviour with the lowest coercivity value for nanoparticles coated by oleic acid. Mössbauer measurements with and without field also reflects that the crystallinity degree is higher for nanoparticles synthesized by thermal decomposition and coated by oleic acid. Moreover, surface spin canting is neglected for these particles probably as a consequence of the oleic acid molecule covalently bond to the surface. The coprecipitation nanoparticles are less crystalline and spin canting exists in both the particles as prepared and those coated with silica.

Introduction

Traditionally, surface-based transducers are employed as biosensors for biomedical diagnostics. However, issues like limited diffusion and steric hindrance at flat surfaces complicate analyte molecule binding for those sensor designs. In contrast, binding process of analyte molecules to nanoparticles (NPs) immersed within the bulk sample solution are far more effective, but the possibilities to remotely sense those binding events are still quite limited. In order to enable remote sensing, a measurable property of the NPs has to change on the adhesion of analyte molecules. In the case of immunological detection, the two main methods of this kind include relaxation detection of magnetic NPs and sensing of the plasmon resonance peak shift of noble metal NPs. However, both of these methods require detection of rather small signals and are, therefore, limited in sensitivity.

A promising approach to overcome these limitations could be offered by optically detect relaxation processes of NPs. A suitable NP type for this purpose would consist, for example, of an elongated magnetic core and a noble metal shell. Here, the magnetic core allows alignment of the nanoparticle by an external magnetic field, while the spectral separation of the longitudinal and transverse plasmon mode of the noble metal shell allows the optical detection of the orientation of its long axis by measuring the adsorption at those two characteristic plasmon excitation wavelengths in linearly polarized light. Here, we present our progress in fabricating and characterizing such elongated core-shell NPs.

Methods

Monodisperse spindle-shaped iron-oxide NPs are fabricated by forced hydrolysis of ferric chloride solutions. The method consists of precipitating ferric hydroxide from a ferric chloride solution with subsequent addition of hydrochloric acid and phosphate ions and aging at 100°C [1]. The NPs are centrifuged and washed several times with distilled water and ethanol. The surface of the spindle-shaped NPs is functionalized with organosilane molecules (APTMS or MPTMS) by incubation in ethanol solution to generate an amine or sulfide moiety coated surface.

Citrate-capped gold NPs (diameter around 4 nm) are prepared by the reduction of chloroauric acid with sodium borohydride. For adhesion to the iron-oxide spindles, the gold NPs are also modified with MHDA or MPTMS by incubation in ethanol solution.

Finally, the Au-NPs are coupled to the functionalized iron-oxide spindles by the gold-amine or the gold-sulfide interaction by incubation in ethanol solution [2].

Results

The shape of the iron-oxide spindles is characterized by atomic force microscopy (AFM) after spreading the NPs from solution onto a flat mica substrate. They are about 50-70 nm in diameter, while the length varies from 350 to 400 nm (see Fig. 1).

Adsorption spectra of pure and Au-NP coupled iron-oxide spindles are shown in Fig. 2. Here, the Au-NPs are modified by an MPTMS layer in order to enable coupling to the iron-oxide spindles, which causes an increase of the plasmon resonance adsorption maximum to about 560 nm due to the larger refractive index of the MPTMS layer as compared to the pure ethanol solvent. The presence of Au-NPs for the coupled sample can be deduced by the increased absorbance around the plasmon resonance frequency of the Au-NPs. As unbound Au-NPs are easily separated from the

spindles by centrifugation, the absorbance spectrum is indicative for successful chemical coupling of the two nanoparticle types.

Magnetic Properties of $\gamma\text{-Fe}_2\text{O}_3$ Nanoparticles Precipitated in Alginate Hydrogels.

L. E. Wenger¹, G. M. Tsoi¹, P. P. Vaishnav², R. Naik³, U. Senaratne³, E. C. Buc³, V. M. Naik⁴

1. Physics, University of Alabama at Birmingham, Birmingham, AL; 2. Physics, Kettering University, Flint, MI; 3. Physics & Astronomy, Wayne State University, Detroit, MI; 4. Natural Sciences, University of Michigan-Dearborn, Dearborn, MI

A study of the magnetic properties of $\gamma\text{-Fe}_2\text{O}_3$ nanoparticles precipitated inside alginate hydrogels has been undertaken. Alginate hydrogels are polysaccharides composed of α -L-guluronic and β -D-mannuronic acid subunits arranged in homopolymorphic and alternating blocks. When divalent cations such as Ca^{2+} and even trivalent cations are added to an alginate solution, the ions become bound between the guluronic acid subunits of the adjacent alginate chains, and thereby produce the so-called egg box structure and ionic interchain bridges. These bridges then result in the gelation of the aqueous alginate solution. Moreover, since alginate gels are highly biocompatible and hydrophilic, an alginate-based system with bound magnetic ions that are subsequently oxidized to form magnetic nanoparticles may be very suitable for biomedical applications such as drug delivery where an external magnetic field can be used for control and manipulation. Correspondingly magnetic nanoparticles were synthesized by cross-linking sodium alginate with Fe(II) or Fe(III) chloride salts in a methanol-water solution and then were oxidized at room temperature under alkaline conditions during which the Fe ions form $\gamma\text{-Fe}_2\text{O}_3$. The iron oxide alginate gels were subsequently recycled through multiple loadings of the salts followed by the oxidation process to determine the effect on the size and concentration of iron oxide nanoparticles. (See table below.) The average particle size D_{XRD} as determined from powder X-ray diffraction spectra was found to range from 2.3-to-3.3 nm with the larger particles resulting from the Fe(II) starting chloride salts and from the greater number of loadings. As expected the weight percentage of iron oxide also increased with the number of loadings and oxidation processes. Moreover, Mössbauer spectroscopy confirmed that the Fe in the resulting nanoparticles existed only as Fe(III) ions and that $\gamma\text{-Fe}_2\text{O}_3$ was the only phase present regardless of the initial Fe valence state of the chloride salt. The ^{57}Fe Mössbauer spectra at room temperature displayed simple quadruple doublets with isomer shifts of 0.141(4) mm/s and quadruple splittings of 0.690(8) mm/s, values typically associated with the presence of superparamagnetic $\gamma\text{-Fe}_2\text{O}_3$. The values of the saturation magnetization M_{sat} at 5 K were also found to be dependent upon the initial Fe valence state and to a lesser degree on the number of loadings as M_{sat} values of 129-142 emu/cm³ of Fe_2O_3 were measured for the Fe(II) starting materials and 79 emu/cm³ of Fe_2O_3 for the Fe(III) materials. In any case, these saturation magnetizations are significantly smaller than the bulk value (408 emu/cm³) for $\gamma\text{-Fe}_2\text{O}_3$. As expected, the nanoparticles exhibited superparamagnetic behavior with the magnetic moments becoming frozen with decreasing temperature as evidenced by the appearance of a bifurcation in the zero-field-cooled (ZFC) and field-cooled (FC) magnetizations and an opening in the M_V -vs.- H hysteresis curves below 40 K. The values of magnetic anisotropy constant ($1.0\text{-}3.5 \times 10^6$ ergs/cm³) determined from the differences between the ZFC and FC magnetizations were found to be significantly higher than the bulk value (1.1×10^5 ergs/cm³) for $\gamma\text{-Fe}_2\text{O}_3$, and are probably due to surface effects. Likewise, the nanoparticle size distributions as deduced from the blocking temperature distribution function $f(T_B)$ based on fits to the differences between the ZFC and FC magnetization curves as well as from fits of the M_V -vs.- H curves in the superparamagnetic regime with a Langevin function indicate fairly broad distributions of particle sizes with the corresponding particle sizes D_{TB} and D_{mag} being comparable to those deduced from XRD measurements as shown in the accompanying table. Not surprisingly the broadness of the distributions also increased with the number of loadings. The

smaller saturated magnetization values found for these $\gamma\text{-Fe}_2\text{O}_3$ nanoparticle alginate composites as compared to the bulk saturated magnetization of $\gamma\text{-Fe}_2\text{O}_3$ combined with the non-zero slope of the high-field magnetization M_V -vs.- H data suggest that these magnetic nanoparticles have a non-negligible surface layer of non-collinear spins of a few tenths of nanometers surrounding a ferrimagnetically ordered $\gamma\text{-Fe}_2\text{O}_3$ core.

Sample	Wt.% Fe	XRD D_{XRD} (nm)	ZFC & FC M_V -vs.- T		M_V -vs.- H

Intermatrix synthesis of magnetic nanocrystals by frontal polymerization and subsequent pyrolysis on iron containing monomer.

E. D. Maciejewska¹, M. Leonowicz¹, A. Pomogailo², G. Dzhardimalieva²

1. Faculty of Material Science and Engineering, Warsaw University of Technology, Warsaw, Poland; 2. Institute of Chemical Physics RAS, Chernogolovka, Russian Federation

Magnetic nanocrystals stabilized in a matrix attract substantial scientific and technological interest. Individual nanocrystals exhibit unique physical properties resulting from size effects and highly developed surface. Such materials can exhibit either superparamagnetic or ferromagnetic properties. The former can find medical applications in targeted drug delivery therapy and as contrast in NMR body screening, whereas the latter is aimed at high density magnetic recording systems. A significant problem arising in the preparation and application of the nanocrystals is their stabilization. Among the methods ensuring stabilization and conservation of the physicochemical properties is synthesis in a polymer matrix, using frontal polymerisation, which enables conversion of monomer to polymer in localized reaction zone 1970s [1,2].

In the current study the nanocomposites containing either Fe or Fe₃C nanocrystals were prepared by frontal polymerisation of iron containing acrylamide (FeAAM) monomer and subsequent pyrolysis of the polymer. The starting monomer, as well as the product of frontal polymerisation had amorphous structure without any trace of iron crystallites. The pyrolysis was carried out at higher temperatures: 643, 773 and 873 K.

All the pyrolysis products were in a form of coarse, irregular powder particles exhibiting broad size distribution, ranging from 50 to 500 µm. The magnetic nanocrystals were distributed within the volume of the powder particles.

The nanocomposites obtained at different pyrolysis temperatures exhibited different structure and microstructure. The product processed at 643 K was amorphous, which means that the pyrolysis temperatures, necessary for fabrication of nanocrystals, have to substantially exceed those recorded in a DSC during dynamic heating. The materials pyrolysed at 773 K and higher temperatures contained nanocrystals. However, composition of the crystallites depended on the pyrolysis temperature (Fig.1). Pyrolysis at 773 K resulted in formation of elementary iron, whereas higher temperatures produced iron carbide (Fe₃C). Moreover, the crystallite morphology was substantially different. The crystallites were embedded in a carbon matrix. Each crystallite is protected by a shell of several graphite layers.

Mossbauer spectroscopy gave more detailed information on the phase constitution. Analysis of the acrylamide complex as well as the polymer after frontal polymerisation revealed the existence of two paramagnetic phases. The polymerisation changes only the amount of these phases, remaining the other parameters unchanged. After pyrolysis the spectra change dramatically showing the existence of ferromagnetic phases. For the material pyrolysed at 773 K the spectra showed coexistence of α-Fe (86.87%) and the remaining paramagnetic phase (31.19%), which correlates with the XRD data. The analysis of the spectra for the material pyrolysed at 873 K proved a coexistence of Fe₃C (86.87%) and some amount of α-Fe (3.17%). The remaining paramagnetic phases amount to 10.96%.

The polymeric material is paramagnetic. The magnetic properties appear after pyrolysis. The phase constitution of the obtained nanocomposites affects their magnetic properties (Fig. 2). For the nanocomposites containing iron room temperature saturation magnetization and coercivity were 100 emu/g and 15.3 kA/m, respectively. The rather high coercivity, about twice the value measured for Armco iron, suggest that some amount of carbon went into solution with Fe. For the iron car-

bide containing material the magnetization and coercivity values were 40 emu/g and 48 kA/m, respectively. The loops were closed and symmetrical, and their shape was characteristic of ferromagnetic material. Low temperature magnetic studies confirmed that the materials did not show superparamagnetic behaviour.

Concluding, iron or iron carbide nanocrystals can be processed by frontal polymerisation of acrylamide iron nitrate complex, followed by pyrolysis. Application of this procedure forms nanocrystals, stabilizes the nanostructure and enables processing of nanocrystals within a narrow window of sizes.

Composition of the nanocrystals, their size, morphology and magnetic properties can be tailored by pyrolysis temperature.

In this study iron (10 nm) and iron carbide (10-80 nm) nanocrystals were produced. The material exhibits ferromagnetic properties.

Synthesis of L10 (FePt)1-xAu Nanoparticle Monolayer on Polyimide Substrate.

J. Kim, R. Kim, N. Oh, H. An, C. Yoon, Y. Kim, C. Kim
Materials Science and Engineering, Hanyang University, Seoul, South Korea

L10 FePt nanoparticles are often considered for future high density magnetic recording medium because of the large coercivity resulting from the high magnetocrystalline anisotropy [1]. In fabricating the FePt nanoparticles, wet chemical methods, in general, produce superior quality nanoparticles in terms of size distribution and composition. Chemical methods, however, typically involve organic surfactants to drive the self-assembly of prefabricated nanoparticles so that monolayer configuration cannot be easily achieved on a large scale. In present study, we demonstrate that monolayer of ordered L10 FePt nanoparticles can be produced on a polyimide (PI) film for possible applications in flexible magnetic data storage. In addition, we show that the size distribution of the nanoparticles can be further improved by alloying the nanoparticles with Au.

In order to synthesize (FePt)1-xAu nanoparticles on a PI film, the PI precursor (p-phenylene biphenyltetracarboximide type polyamic acid) dissolved in N-methyl-2-pyrrolidinone was spin-coated on a Si substrate. The PI precursor was imidized at 400 °C for 1 hour under vacuum to produce 40-nm-thick PI film. A thin layer (0.2 – 0.8 nm thick) of Au was deposited by thermal evaporator on the PI film. On top of the Au layer, 3.2-nm-thick Fe-Pt layer was deposited using dc magnetron sputtering. To form the L10 structure, the deposited film stack was annealed in vacuum (10⁻³ Pa) at 800 °C for 1 hour. Initial and post-annealed compositions were verified using energy-dispersive x-ray spectroscopy.

Transmission electron microscopy (TEM) image of the Fe₅₂Pt₄₈ nanoparticles without Au is shown in Fig. 1(a). In order to obtain nearly equi-atomic ratio of Fe and Pt, the initial composition of the Fe-Pt film was deliberately enriched in Fe to compensate for the preferential etching of Fe by the PI film during annealing. Discussion on the nanoparticle formation mechanism was detailed elsewhere [2]. The average particles size for the Fe₅₂Pt₄₈ nanoparticles was 5.1 ± 1.8 nm. Introduction of the Au into the FePt particles as seen in Fig. 1(b) drastically changed the particle morphology as well as the particle density. While the average particle size for (FePt)₉₁Au₉ decreased to 3.8 ± 1.1 nm, the size distribution became considerably tighter. The size distribution curves in Fig. 1(c) clearly illustrate improved particle size distribution incurred by alloying the FePt particles with Au. Moreover, the particle number density increased from 4 × 10⁹ particles/mm² to 1 × 10¹⁰ particles/mm² with Au. The inset in Fig. 1(b) verifies that the particles were formed in a monolayer. It was previously shown that Au deposited on the PI film formed finely dispersed nanoparticles due to the minimal wettability of Au on the polymer film [3]. It is conjectured that the Fe-Pt film tended to heterogeneously nucleate and grow on the preexisting Au nanoparticles, resulting in improved particle size distribution.

Electron diffraction patterns in Fig. 2 demonstrate that both Fe₅₂Pt₄₈ and (FePt)₉₁Au₉ nanoparticles were converted from the as-deposited fcc structure to the ordered face-centered tetragonal structure by annealing at 800°C. Lattice parameters estimated from the diffraction patterns were a = 0.39 nm and c = 0.38 nm, closely matching the literature values. Figure 2(b) also indicates that the (FePt)₉₁Au₉ nanoparticles formed single-phased solid-solution. Au at 27 at. %, however, led to additional peaks corresponding to metallic Au. The result agrees with the report by Hono and co-worker who estimated the solubility limit of Au in FePt to be around 20 at. % [4].

We demonstrated that monolayer of well-dispersed FePt nanoparticles, potential candidate for high-density magnetic data storage medium, can be formed on a polymer film by physical deposition. It

was also shown that particle density and size distribution can be substantially improved by alloying the magnetic nanoparticles with Au.

The technique of gas phase aggregation [1] has been used to prepare partially oxidized Co nanoparticles by allowing a controlled flow of oxygen gas into the aggregation zone. This method is clearly different from the oxidation in a secondary chamber of a beam of preformed particles [2]. The sputtering gas (Ar) pressure was 0.1 mbar. The nanoparticles were deposited on glass substrates positioned perpendicular to the beam in a secondary chamber. Preliminary transmission electron microscopy characterization shows that the mean size of the particles is about 5 nm. Two series of samples (thin films), corresponding to two different high-purity Co cathodes, were prepared as a function of oxygen pressure (P_{ox}) in the aggregation chamber. Figure 1 shows the saturation magnetization of the two series (black and red data points) normalized by the amount of deposited material. It exhibits the expected decreasing trend with increasing oxygen pressure. In fact, this synthesis technique may be used to prepare pure fcc CoO nanoparticles by employing adequately selected oxygen pressures, as it points out the absence of any other crystallographic phases in the x-ray diffraction pattern of the sample prepared with $P_{\text{ox}} = 3.3 \times 10^{-3}$ mbar (series B).

The magnetic behaviour of the samples was characterized measuring hysteresis loops and the thermal dependence of the magnetization (at 100 Oe) after conventional field (FC) and zero-field cooling (ZFC) protocols. For samples prepared under a sufficiently high oxygen pressure, the room temperature magnetic response showed neglectable coercivity and high saturation fields, suggesting superparamagnetism. (Note that the reference sample grown without oxygen did not show such behaviour, i.e., the strong direct exchange and dipolar interactions between the touching particles stabilizes them in the case of essentially pure Co nanoparticles [3]). As an example, Fig. 2 shows the FC and ZFC magnetization curves measured in the sample marked with a blue arrow in Fig. 1 ($P_{\text{ox}} = 10^{-3}$ mbar). The curves show that the sample is certainly superparamagnetic at room temperature, with a blocking temperature of about 240 K. The room temperature instability of our partially oxidized particles can be explained by two factors: (i) the reduction of the magnetic moment (or ferromagnetic particle size), and, probably more importantly, (ii) the inhibition of direct exchange coupling between oxide-surrounded ferromagnetic regions. The question of whether the morphology of the partially oxidized particles is core-shell-like or a more disordered one remains to be investigated.

There is also another characteristic temperature, signalled with the symbol T_0 , in the ZFC curve shown in Fig. 2. The magnetization is constant up to this temperature, but increases rapidly above it. This feature is interpreted as stemming from the disappearance of an anisotropic exchange coupling between the Co and CoO phases, which would pin the moment of the Co regions in their originally frozen directions [4], i.e., T_0 is the exchange-bias onset temperature. In fact, a large shift was observed in the hysteresis loop measured at 80 K after cooling in a field of 10 kOe. An account of the exchange-bias properties of the samples will be given elsewhere.

In short, a method to synthesize metal-oxide composite films with properties controlled at the nanoscopic level is proposed: reactive gas phase aggregation. It may also prove to be useful in the synthesis of pure CoO nanoparticles.

 2. Faculty of Science, DIC, Charles University Prague, Prague 2, Czech Republic

A metastable ϵ -Fe₂O₃ phase attracts much attention owing to enormous room-temperature coercivity, H_c (up to 2 T in some reports)[1]. In spite of investigations by in-field Mössbauer spectroscopy [2] and neutron diffraction [3], the real microscopic mechanism leading to the huge coercivity observed is still unclear. So far, effects of the shape of nanoparticles or their possible core-shell structure yielding additional magnetic exchange interactions in the interface were not much considered [4]. In order to inspect the effect of substitutions on the ϵ -phase stability, and modifications of the magnetic properties, a series of samples doped by Al and Ga was prepared. Magnetic properties of the obtained materials were studied by magnetization measurements in the temperature range 2–1000 K and magnetic in fields up to 14 T.

The ϵ -X_{1/2}Fe_{3/2}O₃, X = Al or Ga samples were fabricated using a technique based on the solid-state synthesis developed by Hutlova [5] (for details, please see [6,7]). In the first step, we obtained a composite of the X_{1/2}Fe_{3/2}O₃ nanoparticles embedded in an amorphous SiO₂ matrix. The composite powders were annealed at 1000°C for 9, 10 and 15 hours, respectively, in order to study the effect of the heat treatment time on the particle size and phase composition. The silica matrix was subsequently removed by a leaching procedure [3]. Final products (both the composites and the isolated nanoparticles) were characterized using powder X-ray diffraction (XRD), Mössbauer spectroscopy, and high-resolution transmission electron microscopy (HRTEM).

The characterization procedure confirmed single-phase materials (no sign of presence of hematite or maghemite phases). The Al and Ga atoms, respectively, substitute the Fe atoms preferably as revealed by Mössbauer spectra analysis and XRD pattern refinements. Magnetic properties of the substituted materials differ significantly from the binary ϵ -Fe₂O₃ phase. The low-field temperature dependence of zero-field cooled (ZFC) and field-cooled (FC) magnetization, respectively, measured in the temperature range 2–350 K show a furcation at the highest-reached temperature (350 K) for the Al- and Ga- substituted samples, in contrast to the pure ϵ -Fe₂O₃ (as demonstrated for the Al sample in the Figure 1, left panel). The series of order-to-order magnetic phase transitions exhibited by the pure ϵ -Fe₂O₃ in the 80–150 K range lacks; only a broad decay below ~100 K may be attributed to the relics of the ϵ -Fe₂O₃ magnetism. The high-temperature magnetization measurements revealed a shift of the para-to-ferrimagnetic magnetic phase transition in the pure ϵ -phase (480 K) to lower temperatures for the Al- and Ga- substituted samples (Figure 1, right panel). The evolution of the coercivity with temperature deviates significantly from the trend observed for the ϵ -phase; the transition from the large coercivity state to the magnetically soft state below 100 K was not observed. In contrast both the Al and Ga substituted samples show continuous decrease of the coercive field with increasing temperature. The observed decrease of the absolute value of the coercivity at room temperature (typical hysteresis loops of two composites are shown in Figure 2) can not be directly attributed to the substitution effects [4], however, we may conclude, that the Al and Ga insertion on the Fe sites causes a dramatic change of magnetic properties keeping the same crystal structure.

Synthesis of materials with controlled particle size in nanometer regime is an active area in the field of materials research. With the control over particle size the electronic and magnetic properties of material can be tuned. To study the effect of nanometer dimensions on the properties of Heusler alloys, a first example of Co₂FeGa Nano-Heusler is presented. So far only few publications have appeared [1,2] and some alternative strategies are in preparation [3,4]. Since Heusler compounds have a similar potential as Perovskite, this achievement becomes even more sparkling. We have manufactured the targeted monodisperse nanoparticles of Co₂FeGa with size between 5 and 20 nm. Adjusting accurate stoichiometry is important for the properties of these compounds, which in case of Co₂FeGa nanoparticles was determined with EDX and EXAFS and the exact structure was determined by appropriate superstructure reflexes. Beside the HRTEM investigations, XRD (for cobalt and iron k-edges), NMR, Moessbauer spectroscopy, XMCD investigations were accomplished. The 111 and 200 superstructure reflexes of the L21 structure refers to a high order of the nanoparticles of 16-20 nm. Figure 1 shows the HRTEM images of a Co₂FeGa Heusler nanoparticle. The nanoparticles of 20 nm show the moment expected from the Slater Pauling and a high curie temperature. The moment of 5 μ B per formula unit corresponds also to the bulk moment and permits the conclusion that the particles are half metallic ferromagnetic. Moessbauer investigations of 5nm large particles show, in accord with magnetic measurements, superparamagnetism, while larger nanoparticles (20 nm) show ferromagnetism up to high temperatures. The superparamagnetic nanoparticles are of great importance for the biotechnology, since they do not show agglomerate formation below the blocking temperature, if they are separated by appropriate spacer ligands. First attempts with Co₂FeGa show that these can not only be coated with carbon layer as a protection against corrosion but can also be functionalised. Heusler nanoparticles permit therefore most varied applications, far beyond the well-known applications of CoFe and FePt. Somewhat larger nanoparticles are suitable because of their magnetic characteristics for the data storage and as halfmetallic ferromagnets their employment in spin electronics is of great importance.

In summary, we have synthesized and characterized Co₂FeGa Heusler nanoparticles of different sizes. The synthesized Co₂FeGa Heusler nanoparticles were characterized by HRTEM, XRD and Mossbauer. All peaks of XRD patterns can be attributed to a L21 Heusler structure with the lattice constant $a_0=0.537$ Å. The size of the particles, as determined by transmission electron microscopy, is between 5-20 nm. Ferromagnetic behaviour of the particles as determined by the SQUID is presented and compared with the bulk Co₂FeGa Heusler alloy.

Introduction

Smart nanoparticles (NPs) of multiple components offer thrilling opportunities in fundamental studies and multidisciplinary-interweaved nanotechnology that has rapidly grown with tremendous success in many areas including medicine, life science, materials science, environment, electronics, and energy [1]. Since metallic alloy NPs have been extensively investigated for various purposes, particularly the integration of magnetic and optical elements in one single entity promises multifunctionality for potential applications, we have prepared magnetic-optical AuFe alloy NPs via a one-pot polyol process [2]. In this work, we report the giant diamagnetism observed in the zero-field cooled (ZFC) curve of the Au_{0.5}Fe_{0.5} NPs, as great interest is stimulated with shrinking dimension that giant diamagnetism ensues in such nanosystems, which is an omnipresent property of matter screening an external magnetic field by the electrons in the matter [3].

Experiment

The monosized AuFe NPs were synthesized by a polyol process from mixed precursors, gold acetate and iron (III) acetylacetonate. A typical synthesis was carried out in a flask, mixing Au(OOCCH₃)₃ and Fe(acac)₃ in 1:1 in octyl ether with 1,2-hexadecanediol and a surfactant [2]. The reaction mixture was first heated and refluxed at a lower temperature and then rapidly raised to a high temperature to complete the reaction. Ethanol was added to the reacted mixture to precipitate the nanoparticles. The synthesized AuFe NPs were characterized by various tools, including XRD, TEM, UV-Vis, XPS, VSM and SQUID.

Results and Discussion

From the characterization, the fusion of the two elements into one nanostructure entity retains the optical and magnetic properties of the individual components. The XRD and TEM analysis confirms the formation of the alloy nanostructure with a narrow distribution of particle sizes and provides the detailed structural arrangements. Fig. 1(a) shows that the nanoparticles are spherical in shape and indicates that single NPs comprise several distinct sectors, as corroborated by high resolution imaging in Fig. 1(b) that reveals high crystallinity and some disorder. The UV-Vis measurements display an absorption band at ~560 nm and the AuFe nanoparticles can be rendered water soluble after thiolation. The magnetic investigation shows the superparamagnetic behavior of the nanoparticles at room temperature. Fig. 2(a, b) is the M~T curves of the AuFe NPs in the FC and ZFC modes under two different applied fields. Under the field of 100 Oe (Fig. 2(a)), the curves reflect typical behavior of a nanoparticles system. However, magnetic anomaly occurs when the field is 5 Oe. According to Fig. 2(b), the susceptibility in the ZFC curve initially, with decreasing temperature, increases to a maximum at ~175 K, and then reduces to become negative at ~100 K. Below the temperature, the susceptibility continues to progress to a large negative value of -1.5×10^{-2} emu/gOe, though the FC curve remains positive over the whole temperature range. Fig. 2(c) sums up the ZFC curves under the fields upwards from 5, 20, 50, 100, 500 to 1000 Oe, respectively. The finding of the giant diamagnetic susceptibility on the order of -10^{-2} emu/gOe is fascinating, as a giant negative magnetic susceptibility is associated with superconductors where the

paired electrons expel all the external magnetic flux to achieve perfect screening. The mechanism leading to the giant diamagnetism in the AuFe NPs may incorporate the response of spin glass in AuFe systems, mediation by the coexistence of order-disorder in the individual NPs, induced large diamagnetism in nanostructured Au and/or possible superconducting state [3].

The nanoparticles (NPS) are the subject of intense research activities in the last decade [1]. Progress in chemistry made it possible to synthesize nanoparticles in the wide range of sizes down to several nanometers [2,3], but at the same time NPS exhibit large varieties of structural and, therefore, of electronic and magnetic properties. So, the further experimental investigations aimed at establishment of a correlation between structure and properties of NPS are highly desirable.

Here, we concentrate our attention at core-shell bimetallic FeRh_{1-x} nanoparticles ($x = 50, 80$) that could be considered as a good target to explore the relation between the chemical distribution and an order inside NPS and their magnetic properties [4]. FeRh_{1-x} nanoparticles were synthesized by simultaneous decomposition of stoichiometric quantities of Fe[N(Si(CH₃)₃)₂]₂ and Rh(C₃H₅)₃ in mild conditions of temperature and hydrogen pressure.

Magnetic properties of FeRh_{1-x} nanoparticles have been studied with X-ray absorption spectroscopy and X-Ray Magnetic Circular Dichroism (XMCD) near the K edge of Fe and the L_{2,3} edges of Rh. Whereas the former technique is sensitive to the local electronic structure and charge at the absorbing atom, the latter provides unique information about magnetic moments carried by the absorbing atom.

The XMCD measurements reveal different values of the spin and orbital magnetic moments at Rh atoms depending on Fe concentrations and on the way of NPS have been prepared. On the other hand, the magnetic moment at Fe atoms monitored via multielectron excitations and magnetization of the 4p states is found to be nearly the same for all samples. The influence of NPS structure on orbital and spin contributions of magnetic moment at Rh atoms are discussed.

Surface-induced magnetic anisotropy of impurities.

A. Szilva¹, L. Szunyogh¹, G. Zarand¹, C. Muñoz²

Investigaciones Científicas, Madrid, Spain

In order to explain the thickness dependence of the amplitude of the Kondo resistivity in thin films of dilute magnetic alloys [1], the role of the spin-orbit (SO) coupling has been outlined theoretically that in the presence of a surface gives rise to a level splitting of an impurity spin, decreasing thus the freedom for spin-flips needed to obtain a sizable Kondo effect [2]. By using a suitable fit to the measured amplitude of the Kondo resistance, in the case of thin films formed by a dilute $Au(Fe)$ alloy Újsághy *et al.* estimated a spin-blocking depth of about 180 Å, where the level splitting should be higher than, or at least comparable to, the energy-scale fixed by the Kondo temperature, $T_K = 0.3 \text{ K} \sim 0.03 \text{ meV}$.

In this contribution we present detailed numerical studies of the magnetic anisotropy energy of an atomic-like impurity near the surface of a metallic host (Au and Cu), the valence band of which is described in terms of a realistic tight-binding surface Green's function technique. Two models are discussed and compared, namely, (i) when spin-orbit coupling is taken into account for the d -band of the host [2] (HSO model) and (ii) when the impurity's d -level experiences strong spin-orbit splitting due to Hund's rule coupling [3] (LSO model). The level-splitting of the impurity's spin-states is calculated within Abrikosov's pseudofermion representation using Green's function perturbation technique in leading order of the exchange interaction between the impurity and the host atoms. For large distances, d , from the surface an asymptotic analysis implies that in both cases the magnetic anisotropy constant is an oscillating function of d with a period determined by the extremal vectors of the host's Fermi Surface and with an amplitude decaying proportional with $1/d^2$.

In figure 1 the magnetic anisotropy constant, K , as calculated within the HSO model is shown for the case of a (001) surface of Au metal. As seen, despite of the large spin-orbit coupling in the host's d -band ($\sim 0.7 \text{ eV}$) the range of the magnitude of K is well below $0.1 \mu\text{eV}$. In figure 2 the level splitting of a d^1 impurity with large on-site spin-orbit coupling, described thus in terms of a $J_{3/2}$ multiplet, is displayed for the case of (001) surfaces of Au and Cu. Noticeably, the magnitude of K is of order of $0.1\text{--}0.01 \text{ meV}$ even for quite large distances. Since in this case the anisotropy is due by the orbital structure of the spin-states that couples to the tetragonal crystal field induced by the surface, it is not surprising that K is larger for a Cu metal host than for Au.

Our numerical results, thus clearly suggest that in the asymptotic regime the host-induced magnetic anisotropy energy is by several order of magnitude smaller than that raised by the strong local spin-orbit coupling. In the latter case it is even large enough to explain the thickness dependence of the Kondo resistance observed experimentally [3]. We also explore, in particular, the LSO model to study the magnetic anisotropy distribution of impurities in metallic clusters.

The interest in bi-magnetic core-shell nanoparticles is steadily increasing due to the possibility to obtain enhanced magnetic properties. Particularly, since the report on the use of exchange bias to overcome the superparamagnetic limit [1], the amount of experimental and theoretical work on passivated ferromagnetic (FM) nanoparticles coated with the corresponding antiferromagnetic (AFM) oxide layer has increased in the recent years [2]. Here we present the study of inverted AFM-core|FiM-shell systems, as opposed to the typical FM-core|AFM-shell obtained from oxidation of transition metal nanoparticles. The inverse core|shell particles have been prepared by thermolysis of metal salts in organic solvents to produce the monooxide cores (MnO and FeO) with their subsequent passivation under air yielding the shell (Mn_3O_4 and Fe_3O_4). Such preparation allows us to study for the first time the dependence of the magnetic properties as a function of the antiferromagnetic core size, as opposed to the archetypical ferromagnetic metal-core|AFM metal oxide-shell configuration in which the dependence of magnetic properties on the size of the ferromagnet is studied. The first presented system is composed of narrowly sized distributed MnO| Mn_3O_4 particles with average particle sizes of 5 – 60 nm [3] whereas the second system is composed of monodispersed FeO| Fe_3O_4 particles with particle size of 11 nm, both systems have been prepared by chemical routes. The former system may be considered as a double inverted system since it is composed of an MnO AFM core with a bulk $T_N \sim 122$ K and a Mn_3O_4 FiM shell with a bulk $T_C \sim 43$ K (i.e., $T_C < T_N$ as opposed to conventional exchange biased systems). The latter system is composed of FeO| Fe_3O_4 , with $T_N \sim 200$ K $<$ $T_C \sim 600$ K. Transmission electron microscopy and x-ray diffraction studies reveal that the MnO| Mn_3O_4 particles are composed of a roughly constant 5 nm Mn_3O_4 shell with a varying MnO core size (0–50 nm). As can be seen in Fig. 1, for the FeO| Fe_3O_4 particles a roughly constant 3 nm Fe_3O_4 shell with a 5 nm FeO core is obtained. The exchange-coupling between the AFM cores and FiM shells give rise to a number of magnetic effects such as enhanced coercivity and loop shifts (exchange bias), or increased thermal stability of the ferromagnetic component. These properties can, in fact, be controlled the AFM core size, as can be seen in Fig. 2 for the MnO| Mn_3O_4 particles. Remarkably, in the case of MnO| Mn_3O_4 particles the exchange coupling effects vanish at T_C of the Mn_3O_4 shell, whereas for FeO| Fe_3O_4 they disappear at about T_N .

Analysis of Conduction Noise Attenuation by Magnetic Composite Sheets on Microstrip Line by Finite Element Method.

S. Kim, S. Kim, G. Ryu

Materials Engineering, Chungbuk National University, Cheongju, South Korea

Ferromagnetic metal particles or thin films have been proposed as the near-field noise absorbing materials in miniaturized RF circuits or devices [1]. Microstrip or coplanar lines are typically used to determine their noise absorbing capability by measuring reflection and transmission parameters (S_{11} and S_{21} , respectively). Absorption loss of those magnetic materials (in the form of thin composite sheets or films) is influenced by many factors such as material parameters, frequency, and sample dimension. It is, therefore, recommended to use a simulation technique in the determination of noise absorbing capability by modeling the actual system. In this study, Conduction noise attenuation by composite sheets of high magnetic and dielectric loss has been analyzed by using electromagnetic field simulator (Ansoft HFSS 9.0) which employs finite element method (FEM) and adaptive meshing. The simulation model consists of microstrip line with planar input/output ports and noise absorbing materials (polymer composite sheets of iron flake particles with high magnetic and dielectric loss [2]) as shown in Fig. 1. Modeling parameters are dimension and material constants (conductivity, permeability, permittivity, loss tangent) of the microstrip line and noise absorbing sheet. Input port is excited by TEM-mode wave with characteristic impedance of 50 Ω . S_{11} and S_{21} parameters are calculated as a function of frequency and their dimension (sheet size and thickness). Attaching a noise absorbing sheet with a dimension (width = 50 mm, length = 25 mm, and thickness = 1 mm), almost constant value of S_{11} (about -12 dB) is estimated and S_{21} is decreased with frequency from 0 dB (at 0.5 GHz) to -25 dB (at 6 GHz). The calculated power absorption is almost the same as the measured value as shown in Fig. 2. The power loss increases with frequency in the lower frequency region below 2 GHz and then saturates to a maximum value of about 90%, which is due to material loss (magnetic and dielectric) of the composite sheet. The attenuation of conduction noise (both electric and magnetic field) by the magnetic composite sheets is visually shown in the microstrip line model. The power absorption increases with sheet length (along the microstrip line) and thickness as shown in Fig. 3, since the power dissipation by material loss (magnetic and dielectric) is proportional to the sheet volume covering the strip conductor. On the while, the influence of sheet width (at a fixed length) on the power absorption is not so significant as shown in Fig. 4, since the electromagnetic field is concentrated along the microstrip line. The estimated frequency and size dependency of power absorption is well consistent with experimental results published in the previous study [2]. It is concluded that the proposed simulation technique can be effectively used in the design and characterization of noise absorbing materials in the RF transmission lines.

Microwave Absorbers of Two-layer (Dielectric/Magnetic) Composite Laminates for Wide Oblique Incidence Angles.

S. Kim, J. Kim

Materials Engineering, Chungbuk National University, Cheongju, South Korea

Advanced microwave absorbers for wide oblique incidence angles are required in many applications including wireless communication or vehicle identification in ITS (Intelligent Transport System) where 5.8 GHz DSRC (Dedicated Short Range Communication) system is applied. Multiple reflection or non-specular scattering of electromagnetic wave from pavement, sidewalls, over-bridge, canopy in toll-gate, and other nearby structures deteriorates electromagnetic environment and results in undesired communication outside a specified region [1]. In this study, two-layered (dielectric/magnetic) microwave absorbers are designed for the achievement of low reflection coefficient over wide incidence angles at 5.8 GHz. The absorbing layer of composite sheets containing magnetic iron flake particles and the surface layer of low dielectric constant containing small amount of carbon black (and hence leading to impedance matching) have been made by conventional composite fabrication process. The complex permeability and complex permittivity of the composites were determined by reflection/transmission technique. The reflected power was measured by free-space arch test with variation of incident angle for both TE (transverse electric) and TM (transverse magnetic) polarization [2]. On the basis of transmission line theory, reflection loss has been calculated with variation of incident angles. Fig. 1(a) shows the reflection loss for normal incidence of plane wave determined in the single-layer composite (with thickness 1 mm) of iron flake particles terminated with metal. A high value of reflection loss (less than -1 dB) is predicted in GHz frequencies. Most of the power is reflected due to its high value of permeability and permittivity. Impedance matching layer is required to minimize wave reflection from such a highly reflecting surface. Fig. 1(b) shows the reflection loss determined in the two-layer composites laminate where the carbon black composite (thickness = 7 mm) is attached on the absorbing layer of iron flake particles. The minimum reflection loss (-30 dB) is predicted at 6 GHz. At this optimum thickness of the composite laminates, a low value of reflection loss (less than -10 dB) is predicted for wide incidence angles up to 55° for both TE and TM polarization as shown in Fig. 2. The measured value of reflection loss by free-space measurement is in good agreement with the theoretical value. The two-layer composite laminates consisted of magnetic absorbing layer with high magnetic loss and surface impedance matching layer of low dielectric constant can be proposed for the high potential microwave absorbers for electromagnetic radiation of oblique incidence.

Left-handed properties in the combined structures of cut-wire pair and continuous wire.

V. Dinh Lam, J. Kim, N. Thanh Tung, S. Lee, Y. Lee
Hanyang University, Seoul, South Korea

Recently, left-handed materials (LHMs) have attracted great attention because of their fascinating electromagnetic properties. Based on the Pendry's suggestion [1] and the Veselago's original prediction [2], a large number of both theoretical and experimental reports confirmed the existence and the main properties of LHMs. In this study, we experimentally studied the LH behavior of the combined structure of cut-wire pair and continuous wire. The cut-wire pair structure consists of a pair of finite-length wires, is separated by a dielectric layer. To achieve the LH properties, the cut-wire pairs were combined with continuous wires.

The samples were fabricated by using the conventional printed circuit board (PCB) process with copper patterns (36 μm thick) on both sides of a dielectric PCB (0.4 mm thick) with a dielectric constant of 4.8. These structures were designed and fabricated, and their transmission spectra were measured in the microwave frequency regime. The periodicity along the x and the y directions was achieved by printing the 2-dimensional array of patterns on the planar PCB. The periodicity along the z direction was obtained by stacking a number of pattern boards with a lattice constant of $az = 1$ mm.

Figure 1 shows the measured transmission spectra of the cut-wire pair structure with different numbers of layer. Evidently there is a band gap between 13.4 and 14.8 GHz in the transmission spectrum. This band gap becomes more evident when the number of layers increases, as expected. Another band gap begins to be formed at ~ 17 GHz. The observed results are similar to those in Ref. 3. Hence, it is confirmed that the first band gap in 13.4 – 14.8 GHz is due to the magnetic resonance, providing a negative magnetic permeability, and the second band gap starting at ~ 17 GHz is due to the electric resonance, providing a negative electric permittivity. This result reveals that the cut-wire pair structure exhibits both a magnetic and an electric resonance as the split-ring resonator. By combining the cut-wire pairs with continuous wires, one can get a combined structure that exhibits the LH behavior.

Figure 2 presents the photograph of fabricated combined structure and the measured transmission spectra of cut-wire pair, continuous wire and combined structures. For the comparison, all the structures here consist of three layers. The cut-wire pair structure displays a stop band between 13.4 and 14.8 GHz, corresponding to the magnetic resonance frequency range where $\mu < 0$, while the combined structure exhibits a pass band between 13.4 and 14.8 GHz, this pass band exactly coincides with the stop band of the cut-wire pair structure. Based on these results and the previous study [3], it is understood that the pass band between 13.4 and 14.8 GHz in the transmission spectrum of the combined structure indicates a clear evidence for the appearance of LH behavior.

There exists another pass band between 15.3 and 17.3 GHz in the transmission spectrum of the combined structure, and in this pass band both the permittivity and permeability are positive. Thus, this is a right-handed transmission band. The LH behavior of a combined structure can still be observed as the width of cut-wire pair increases until the cut-wire merges with the continuous wire, the so-called fishnet structure as shown in Fig. 3.

Electromagnetic interference and shielding of valve hall in HVDC converter station.

C. Gao¹, Z. Zhao¹, S. Wang²

1. North China Electric Power University, Baoding, China; 2. Northeast Electric Power Design Institute, Changchun, China

Abstract—Radiate electromagnetic interference (EMI) from valve hall fires is analyzed by numerical method and measurement. According to the character of EMI, the practical shielding technique is discussed to satisfy the relative standards.

1. Introduction

For the widely use of HVDC, the EMI of HVDC converter station are paid more attention [1]. In this paper, we analyzed the radiated EMI of ± 500 kV converter station by both the electromagnetic field numerical method and measurement. Based on the results obtained, the shielding technique must be used to the valve hall is discussed to satisfy the relative standards

2. EMI of valve hall

In general, EMI noise from the valve hall includes radiation and conducted propagation. Here we focus on the radiated noise due to the valve fires. EMI induced by corona discharges is ignored because it can be held to acceptable levels by proper electrical design of the bus bars and the hardware of the stations.

As the radiated noise may interfere the instruments around and the radio, some standards limit the level of EMI. The electric field intensity can not exceed 10 V/m to ensure the instruments around or in control room work properly according to IEC-6100-4. And the radio interference level (RIL) shall not exceed 40 dB μ V/m at the locations under concern as shown in Fig. 1.

Due to the complexity of the metal structures in valve hall, electromagnetic field numerical method must be used to analyze its EMI problem accurately. Here we use moment method [2] to compute the EMI level of valve hall by building an antenna model for valve tower as shown in Fig. 2. In our model, the metal structures are treated as wires and patches. The impedances of the valve are set as frequency independent according to the test results. And then EMI level for different frequencies are computed. It should be mentioned that the wall of valve hall is not considered in our model. So the results computed are those ignored the shielding effectiveness of wall.

Both the electric field intensity and RIL level are analyzed. Fig. 4 shows the electric field intensity at the edge of valve. It decreases with the frequency increasing and is higher than 10 V/m when the frequency is lower than 100 kHz.

Fig. 4 shows the RIL level at the locations under concern. They are the directional diagrams of RIL level for 1 MHz and 20 MHz when the distances to the valve hall are 450 m. We can see at frequency of 20 MHz, RIL level exceed 40 dB μ V/m remarkably.

3. SHIELDING TECHNIQUE

Based on the relative standards and according to results computed, the EMI must be attenuated. Shielding is the useful method to decrease the RF noise and the shielding effectiveness of the wall should not be less than 40 dB. As only metal sheet can supply such high shielding effectiveness for RF, the wall of the valve hall must be built with metal sheet. In practice, the cladding of the wall should be consist of steel sheets with a thickness which is not thinner than 0.5 mm, and the distance between electrical contacts of sheets should not be larger than 35 mm. The shielding effectiveness of a real hall is measured and the results show that its SE is higher than 40 dB.

Here we represent some results measured and compare them with those computed by our method after the real shielding effectiveness of wall is considered. At the edge of hall, the electric field intensity measured by lower frequency sensor are 100-200 mV/m at the frequencies are several

decades KHz. The corresponding results computed are 10-20V/m at the same positions, considering the real SE of wall is about 40 dB at this range of frequency, we can say that our method is accurate and the SE of wall is practical.

Study of coupling on parallel microstrip lines due to magnetic absorber sheet.

V. B.regar, J. Koselj, B. Drnovsek
 Nanotesla Institute, Ljubljana, Slovenia

Absorber sheets based on magnetic-loaded composite are currently used as near-field absorbers for suppression of metal casing resonances, RFID enhancement and conducted noise suppression [1]. On dense electric circuits, single absorber sheet can cover large number of circuit connections. However, we observed significant coupling between the parallel microstrip lines even for line separation larger than line width. Signal coupling between transmission lines can present a significant problem [2] and can be increased by magnetic absorber sheets since these materials have relatively large permeability and permittivity. This could have negative effect on the application possibilities of the magnetic absorber sheets on the dense high-frequency circuits. On the other hand, it could lead to new uses in the microwave devices as the coupling effect between parallel lines is exploited for use in various devices like directional couplers or phase shifters [3], and in ferrite-coupled microstrip lines with magnetized ferrite substrate [4].

The aim of this study was to experimentally and numerically investigate the effect of coupling between parallel microstrip lines with applied magnetic-loaded absorber sheet. Numerical models allow us to examine parametrically the effect and identify key parameters of effective coupling, whereas experiments are used as a validation and examination of the effect with actual absorber sheets. The results will enable optimization of the magnetic-loaded absorber sheet for minimum coupling on PCBs, but also evaluation of potential for coupling devices.

For the experimental study microstrip circuits with two parallel lines were used. Lines are 1.6 mm wide with distance between lines 0.8, 1.6 and 3.2 mm. Parallel section is 50mm long, with absorber sheet applied in the middle of this section. Set-up was calibrated to eliminate coaxial cable characteristics from the measurements. Scattering parameters (S_{11} , S_{21} , S_{31} and S_{41}) were measured in pairs, with 50 Ω terminations on the other ports, and were measured both without and with absorber sheet over both microstrip lines. Numerical modeling was done with Comsol Multiphysics software, RF module, and geometry of the model was identical to the experimental set-up.

From the experimental results, shown in Fig.2, it is clear that the application of the absorber sheet greatly enhances the S_{31} coupling at lower frequencies, but at the same time introduces large suppression of the through signal (S_{21}). At lower frequencies the coupling is 10-15dB larger than without absorber sheets on microstrip lines, but in contrast to empty lines after broad peak falls with increasing frequency. Similar curves for S_{21} and S_{31} at higher frequencies indicate that the fall of coupling is due to the damping of the signal and not in change of the coupling itself. The difference in thickness of the absorber sheet affects much more the suppression than the coupling itself (linear effect), but affects also S_{11} and S_{41} .

Further, we numerically analyzed the effect of permeability and permittivity of idealized absorber sheet. Numerical models show changed distribution of magnetic and electric field lines, that gives enhanced coupling between the microstrip lines. The results on Fig.3 show that the real part of the permittivity has the largest effect on the coupling S_{31} , while permeability shows smaller, but still significant effect. In contrast, permeability does not affect much S_{41} , whereas permittivity exhibits large effect. Imaginary parts of permeability and permittivity have an effect mostly on the signal suppression (S_{21}), with permittivity again having larger effect. In addition, we examined both numerically and experimentally the effect of air gap between microstrip lines and absorber sheets and the dimensions of the absorber sheet. Results show that any gap significantly reduced the cou-

pling efficiency and also suppression of S_{21} , whereas change of length gives only proportional change in S_{21} and S_{31} .

The influence of the construction of secondary reaction plate on the transverse edge effect in Single-sided linear induction motor.

S. Lee¹, H. Lee², S. Go¹, K. Kim¹, D. Jung¹, J. Lee¹

1. Hanyang university, Seoul, South Korea; 2. Korea Railroad Research Institute, Uiwang, South Korea

The SLIM with aluminum-on-iron secondary has been favored for ground transportation. The performance of the SLIM depends markedly on the construction of the secondary or reaction rail[1]. Especially, the construction of the secondary reaction plate have a big influence on the transverse edge effect. The early analysis of transverse edge effects in linear induction motors is generally based on an idealized mathematical model[2]. Preston and Reece[3], Oberretl[4] and Lang[5] propose the analytic method and all of these methods allow for a 3-dimensional flux density distribution. These analytic analyses have not only some restriction such as iron to be extended to infinity or iron height and yoke flux distribution but also an impossible thing which is considering a detailed geometry of secondary reaction plate. On the other hand, 3D Finite Element Method can analyze without this restriction and fully consider a detailed secondary geometry data. But So far, there is no paper considering in detail the influence of the construction of secondary reaction plate on the transverse edge effect by using 3D FEM. In this paper, the influence of the construction of secondary reaction plate on the transverse edge effect is fully considered by 3D FEM. Fig 1 shows the analysis model for 3D FEM. this model is only 1 pole model. Both end effect and edge effect can be simultaneous considered by using 3D FEM analysis of full model. But 3D full model FEM analysis using by the present computer resource is impossible so that this paper takes only account edge effect with 1 pole model. Figure 2 (a) shows the 3D analysis result; the distribution of eddy current on the secondary reaction plate has both non-uniform current densities with a transverse component J_z and non-zero current densities with a longitudinal component J_x . Figure 2 (b) represents the transverse component J_z along center line of secondary plate and it is used for the use of an indicator to the transverse edge effect in this paper. Ten analysis models are selected to consider the influence of secondary construction and each model has only a difference in the construction of secondary reaction such as semi-cap or full-cap. Figure 3 shows the results of all models. Figure 4 shows the comparison between the result of 3D FEM analysis and the result of analytic analysis. Since considering a detailed construction of secondary by using analytic method is so difficult, there is a considerable difference between them. But a trend of the result of 3D FEM analysis and the result of analytic analysis is the same. As a result 3D 1pole FEM analysis is a very useful tool for considering the influence of the complex construction of secondary reaction plate on the transverse edge effect. Also it can be used in finding optimal construction of secondary reaction plate.

RF conduction in-line noise suppression effects for the NiFe and Fe magnetic composite.

K. Kim¹, J. Ryu², S. Lee², S. Lee², Y. Choa³, S. Oh⁴

1. Physics, Yeungnam University, Gyeongsan, South Korea; 2. Composite Materials, Korea Institute of Materials Science, Changwon, South Korea; 3. Dept. of Chemical Engineering, Hanyang University, Ansan, South Korea; 4. Dept. of Materials Science and Engineering, Seoul National University of Technology, Seoul, South Korea

In order to enhance the signal integrity, the loss generation of ferromagnetic composite films is one of good countermeasure for the suppression of EM noise emission on transmission line [1, 2]. Therefore, to reduce the eddy current loss and to utilize the high frequency, we evaluated the RF EM noise suppression using the epoxy composite sheet combined with magnetic nanoparticles on transmission line.

The magnetic nanoparticles were fabricated by conventional Electric Explosion Wire (EEW) method. Fe and NiFe pure wires of 0.4 mm in diameter were used. Explosions were carried out in argon at a pressure 1.5×10^5 Pa. One of the main parameters influencing the properties of the produced nanopowder is the specific energy input into the wire W/Ws (where W is the energy input into the wire, Ws is the sublimation energy of the wire). A metal wire was installed between the ground and a high-voltage electrode that was connected to a capacitor bank through a triggered spark gap switch. The wires were fed by a feeding roller installed on the exploding vessel and were guided by a nozzle into the vessel. The electrical energy is deposited in the wire and is heated, vaporized, and turned into plasma. The vaporized metal vapor collide each other and condensed to form a metallic Fe and NiFe nanoparticles with around 100 nm in size. Composites containing metallic particles (NiFe, Fe) were fabricated with the different concentrations of fillers. Metallic particles and resin with net concentrations of 50 wt.% NiFe and 50 wt.% Fe were mixed by a homogenizer for well dispersion, respectively and then they were cured at 120°C. In order to measure the complex permittivity and permeability at the radio frequency region, Agilent N5230A and 7 mm coaxial airline with electrical calibration module (Agilent N3696A) were used. Complex electromagnetic property data were obtained using Agilent 85071E (Material Measurement Software), in which the Nicolson-Ross-Weir method is implicated, from scattering parameters for reflected and transmitted waves over 0.5 GHz ~ 10 GHz. Fig. 1 shows the hysteresis loop of composite sheet for the Fe 50 wt.% epoxy composite and NiFe 50 wt.% composite and the images of magnetic powder, respectively. In magnetization curves, it can be deduced the amount of magnetic NiFe and Fe in composite sheet, which is about 50wt. % by comparison with those of values magnetization in bulk materials. In order to characterize the conduction in-line noise, the transmission line was prepared on printed circuit board by IEC standard (IEC 62333-2) as shown in Fig. 2 (a). The measured s-parameters by network analyzer were converted to power loss, which can be defined by $P_{\text{loss}}/P_{\text{in}} = 1 - (|S_{11}|^2 + |S_{22}|^2)$. Figure 3 shows the permittivity, permeability (a), (b), the measured and simulated power loss (c), (d) for the Fe 50 wt.% epoxy composite and NiFe 50 wt.% composite, respectively. The signal attenuation of the composite sheet with Fe 50wt.% is a little bit higher than that of NiFe 50wt.%. The power loss was simulated by 3D model using the commercial HFSS v.11 program, which the simulated results were a good agreement those of experimental data. When the materials have similar permeability behaviors, the power loss could be dominant with the permittivity values. In same materials, the power loss is proportional to the magnetic moment and loss tangent (this result is not shown here for page limitation). As results, the magnetic powder composite sheet by EEW method is one of good candidate materials for RF noise suppression.

Optimal bulk content of sulfur for high magnetic induction in inhibitor-free 3% Si-Fe strips.

S. Kim¹, J. Soh¹, J. Oh¹, S. Cho¹, S. Han², N. H. Heo¹

1. Advanced Materials Group, Korea Electric Power Research Institute, Daejeon, South Korea; 2. Chungnam National University, Daejeon, South Korea

The 0.15mm-thick 3%Si-Fe alloy strips containing 11, 29, 58, and 92 ppm sulfur were prepared through a vacuum induction melting, hot-rolling and double-stage cold-rolling process with a lubricant. Between each cold-rolling process, an intermediate annealing was performed at 800°C for 20 min under a high vacuum of 7×10^{-6} Torr. Final thickness reduction was 60%. The number of final cold-rolling passes was 9. Prior to vacuum-annealing at 1200°C for 12 h, the strip samples (10 mm \times 100 mm in dimension) were heated to the temperature with a heating rate of 400°C/h or directly isothermal-annealed (approximately 35000°C/h) at the temperature under the flowing hydrogen of 3 liter H₂/min.

The correlation between bulk content of sulfur, area fraction of grains, magnetic induction and heating rate is shown in Fig. 1. Here, the area fraction is nearly equivalent to a volume fraction, because final-annealed strips showed a bamboo-structure. At 400°C/h, a sharp {110}<001> texture was obtained from the strip containing 58ppm sulfur, resulting in an excellent magnetic induction of 1.96 Tesla. A poor magnetic induction was obtained from the other alloy strips showing no or a limited {110} texture. The surface-energy-induced selective growth is mainly governed by the interfacial segregation kinetics of sulfur which forms a convex profile [1]. The convex segregation concentration decreases overall with decreasing bulk content of sulfur. This results in the shortened time or temperature range for {100} or {111} selective growth. It is therefore expected that {110} texture will be much more easily obtained from the alloy strips with a lower sulfur content. However, the anomalous final texture of the 11 ppm strips in Fig. 1 can be explained by the following selective growth kinetics [1],

$$G(t) = M(t) \times [(\gamma_G/r(t)) + (2\Delta\gamma_S/d) + C(t)],$$

where, $M(t)$ is the grain-boundary mobility, γ_G is the grain-boundary free energy, $r(t)$ is the average radius of grains excluding the selectively growing grains, $\Delta\gamma_S$ is the difference in surface energy between the growing grain and the grain which is consumed, d is the strip thickness, and $C(t)$ is the concentration of interface-segregated sulfur that has a strong grain-boundary pinning effect as the negative driving force term.

At a lower bulk content of sulfur, a weak grain-boundary pinning effect can enhance the growth of {100} or {111} grains during the selective growth. This hinders the final selective growth of {110} grains due to the size disadvantage. At a higher bulk content of sulfur, {110} grains are not easy to survive due to the enlarged time period of {100} or {111} selective growth. Therefore, a moderate bulk content of sulfur (i.e., 58ppm sulfur in this study) exists for obtaining the final {110} texture. As shown in Fig. 1(b), the area fraction of {110} texture increased with increasing heating rate. Also the total number of {110} grains increased in the strips containing 58ppm sulfur. In order to obtain an excellent magnetic induction even in the other strips, a much faster heating rate is required [2]. Additionally, the drastic increase in the total number of {110} grains with increasing heating rate is due to the larger {110} grains arising from the selective growth of the initially formed {110} grains which results in the increase in the number of the surviving {110} grains.

Performance Improvement of PM Synchronous Motor by Using Soft Magnetic Composite Material.

G. V. Cvetkovski, L. B. Petkovska

Faculty of Electrical Engineering and Information Technologies, Ss. Cyril & Methodius University, Skopje, Macedonia

Abstract— The paper is presenting some aspects of soft magnetic composite (SMC) material application in electrical machines. The stator core of the analyzed permanent magnet synchronous motor (PMSM), is made of magnetic iron sheets. Three types PMSM stators are analysed: laminated with open slots, laminated with closed slots using SMC and SMC stators. The comparative analysis is based on the magnetic properties and the calculated parameters of each motor model. The studied electromagnetic and electromechanical parameters are flux densities in various sections of the magnetic circuit and electromagnetic and cogging torque. The parameters' values for the three types of stators are calculated using Finite Element Method (FEM).

I. INTRODUCTION

The investigated object is a brushless three phase synchronous permanent magnet Koncar motor type EKM 90M-6 has 36 stator slots and a rotor with 6-skewed SmCo5 surface mounted permanent magnets. The rated data is $I=18\text{ A}$, $T=10\text{ Nm}$ and $n=1000\text{ rpm}@50\text{ Hz}$.

The complexity of the magnetic circuit and the fact that the stator slots in the original design are opened influences the distribution of the magnetic field in the air gap as well as the electromagnetic and cogging torque.

Torque quality is very decisive issue for variable speed drive applications. There exist two undesired pulsating torque components in PM machines which affect the machine performance, one of which is ripple torque arising from harmonic content of the machine voltage and current waveforms and the other is cogging torque caused by the attraction between the rotor magnetic field and angular variations of the stator reluctance. These components not only affect the self-starting ability of the motor but also produce noise and mechanical vibrations.

Therefore, the investigation was focused on the design improvement of the PMSM by using SMC material as stator slot closure as well as for the stator cores in whole. The comparative analysis of the three stator topologies is based on magnetic field distribution in the motor.

II. SOFT MAGNETIC COMPOSITE MATERIALS APPLICATION

The basis for the material whose utilisation is the subject of this paper is bonded iron powder. The most important property of the SMC material, which is the ability to be easily shaped in complex forms. Although the soft magnetic composite materials have low permeability and high specific iron loss at low frequencies in the recent years they became very attractive for use as magnetic core parts or for manufacturing the whole cores in general. Another valuable property of the SMC material is the isotropy of the material and the rather good iron losses at high frequencies. This property makes the SMC material very attractive for producing a stator slot closure for the PMSM. The very fast development of new soft magnetic composite materials with improved magnetic properties goes in favour of the application of this material as stator core magnetic material. In this paper three models of the PMSM are going to be analysed. The laminated stator is made of grain oriented silicon steel with thickness of 0.5 mm, while the SMC material stator cores are made of SOMALOYTM500.

III. MAGNETIC FIELD ANALYSIS

In order to be able to analyse the two models of the PMSM with different stators accurately, a calculation of the magnetic field has to be performed for the three-stator topologies. After the motor

has been properly modelled, a 2D FEM magnetic field calculation of the three models of motors at no load and at rated current load ($I_{ph}=18\text{ A}$) is performed. The distribution of the magnetic field at rated load, the air gap flux density at no load and the electromagnetic torque for the three models is presented in Fig.1, Fig.2 and Fig.3, respectively.

The calculated data from the FEM magnetic field analysis in the postprocessor mode could be also used to calculate some other magnetic and electric parameters necessary for the complete and complex analysis of the three PMSM models. The calculated values of these parameters (air gap flux, air gap flux density, back iron flux density, stator teeth flux density, slot closure average flux density, iron loss in the stator, iron loss in the slot closure, total iron losses, electromagnetic torque and cogging torque [1-2]), are going to be presented and comparatively analyzed in the full version of the paper.

The temperature change of a magnetic material associated with an external magnetic field change in an adiabatic process is defined as the magnetocaloric effect (MCE), which was discovered in iron by Warburg[1]. It can be measured directly (adiabatic temperature change, ΔT_{ad}) or it can be calculated indirectly from the measured magnetization (magnetic entropy change, ΔS_M). Recently, a large magnetic entropy change has been found and intensively studied in Ni-Mn-Ga alloys, due to the possibility to use these materials as active magnetic refrigerants in the magnetic refrigeration technology[2].

The $\text{Ni}_{54}\text{Mn}_{21-x}\text{V}_x\text{Ga}_{25}$ ($x=0, 2, 4$) samples were prepared by conventional arc melting method in argon atmosphere. For homogeneity of samples, ingot was melted several times. And then, the heat treatment was carried out at 110 K in a sealed quartz tube for 9 days and quenched in ice water. Quenching is believed to be important to obtain a high chemical order for this kind of alloys. The samples were examined by the X-ray diffraction and showed the single phase. The magnetic characteristics were performed with a Quantum Design superconducting quantum interference device (MPMS mode) magnetometer in the fields up to 20 kOe. The magnetic entropy change is calculated by the isothermal magnetization measurements.

Fig. 1 shows the temperature dependence of low-field magnetization for the samples. The Curie temperature, T_c was found to be 325, 300 and 265 K and the austenitic transition temperature, T_A was found to be 315, 217 and 124 K for $x=0, 2$ and 4 of $\text{Ni}_{54}\text{Mn}_{21-x}\text{V}_x\text{Ga}_{25}$, respectively. With an increase of the concentration of V for $\text{Ni}_{54}\text{Mn}_{21-x}\text{V}_x\text{Ga}_{25}$ systems, the Curie temperature and austenitic transition temperature decrease due to the dilution of the magnetic subsystem[3].

The magnetic entropy change as a function of temperature for the samples at the external magnetic fields of 20 kOe were calculated and plotted in Fig. 2. As shown in Fig. 2, the magnetic entropy change ΔS_M reaches a maximum value of about 2.49, 1.92 and 1.81 J/kg K for $x=0, 2, 4$ at 325, 300 and 265 K, respectively. With increasing V content, the magnetic entropy change decrease.

 1. *Ingegneria Elettrica, Politecnico di Torino, Torino, Italy*; 2. *Electromagnetics, Istituto Nazionale di Ricerca Metrologica, Torino, Italy*

The steady state behaviour of circuits and systems under ferroresonance conditions can be classified into four different types (fundamental, subharmonic, quasi-periodic and chaotic mode) [1]. The determination of the ferroresonance mode depends on many factors, such as the circuit parameters, the supply voltage and frequency, the shape of the nonlinearity (that is, usually, the magnetization curve or the hysteresis loop of the core of a saturable inductor) [2].

This paper investigates the influence on the ferroresonance mode of the nonlinear behaviour of a ferromagnetic inductance in a RLC circuit, supplied by a controlled voltage generator. The analysis is carried out both by experiment and simulation.

A core constituted by an amorphous ribbon, having small thickness (7 μm), is found to be well suited for the investigation. First, the amorphous alloys present very narrow hysteresis loops and negligible classical losses, making the ferroresonance arising easier [3]; in addition, the application of different field annealing to the same material can sensibly modify the shape of the magnetization curves; this behaviour is shown in Fig. 1 which compares the hysteresis loops of the same amorphous ribbon ($\text{Co}_{67}\text{Fe}_4\text{B}_{14.5}\text{Si}_{14.5}$) obtained after a longitudinal and a transverse field annealing respectively.

Since the presence of the unavoidable circuit resistances (winding resistance, resistance for current measurement) can reduce or prevent the development of the ferroresonance phenomena, an operational amplifier is series connected to the RLC electric circuit. It compensates the drop on the resistive component, removing partially or totally the Joule losses. The importance of this compensation is made evident in Fig. 2, which presents two current waveforms obtained under the same supply conditions with and without the insertion of the operational amplifier. A good agreement between the measurements and computations is found.

The investigations are developed considering different supply conditions, where the amplitude, frequency and waveform (sinusoidal, triangular, rectangular) of the controlled generator voltage are varied. Some amorphous or nanocrystalline ribbons, with different chemical compositions and annealing treatments are characterized under controlled sinusoidal flux with digital hysteresis-graph and used in the experiments. As an example, Fig. 3 reports the measured and computed current evolution in a circuit including an amorphous ribbon inductor $\text{Co}_{67}\text{Fe}_4\text{B}_{14.5}\text{Si}_{14.5}$ with longitudinal field annealing) supplied by a rectangular voltage at 1 kHz; the chaotic mode ferroresonance is well evident. A detailed analysis about the influence of the magnetization curve shape on the ferroresonance phenomena will be reported in the full paper.

I. INTRODUCTION

Polycrystalline strips 80%Ni-Fe [1] have very good magnetic properties, but they are relatively expensive due to high content of Ni. As an alternative to the Ni-Fe alloys (permalloys) the nanocrystalline materials [2] can be used. Nanocrystalline toroidal cores are cheaper and often more useful in instrument transformers [3].

The aim of this paper is the comparison between the total harmonic distortion of the magnetizing current (THD₁) in wound toroidal cores combined from two sub-cores (with the same dimensions) made of grain-oriented electrical steel (SiFe) [4] and polycrystalline Ni-Fe (NiFe) or SiFe and nanocrystalline ribbon (Nano).

II. DESCRIPTION OF COMBINED WOUND TOROIDAL CORES

To increase the intensity of the output signal of an instrument transformer excited with low magnetic fields, the magnetic circuit can be made as a combination of SiFe and another, magnetically softer material, for instance NiFe or Nano.

The magnetic measurements were carried out on toroidal cores with dimensions $d_1 = 145$ mm, $d_2 = 105$ mm and $h = 20$ mm under sinusoidal voltage excitation and frequency of 50 Hz according to the international standard [5].

III. MAGNETIC PROPERTIES OF COMBINED TOROIDAL CORES

According to the measured data (Fig. 1 a) magnetic materials can be characterized by different values of peak flux density (B) and also different relative permeability (Fig. 1 b). Core made of nanocrystalline strip has significantly higher relative permeability than the NiFe, which can be utilized in low magnetic fields, i.e. in a range from 1 to 2 A/m.

In the case of a magnetic core combined from SiFe and NiFe, the resultant values of peak flux density are lower for the same values of magnetizing field than for the SiFe+Nano.

IV. HARMONIC DISTORTION OF MAGNETIZING CURRENT IN COMBINED WOUND TOROIDAL CORES

A distortion of a current waveform can be measured by a coefficient called "total harmonic distortion" [6], which is defined as in equation (1),

$$THD_1 = (\sqrt{I_2^2 + I_3^2 + I_4^2 + \dots}) / I_1 \times 100\% \quad (1)$$

where: THD₁ - total harmonic distortion of magnetizing current (%), I_1 - magnitude of the fundamental frequency of the current (A), I_2, I_3, I_4, \dots - magnitudes of higher harmonics (A).

Comparison of the THD₁ value for various combined cores is presented in Fig. 2.

The single SiFe core offers the lowest harmonic distortion in a magnetizing current (for the same values of flux density). The highest distortion occurs in the single NiFe. For the combined cores SiFe+NiFe and SiFe+Nano, the THD₁ remain in a similar level, but at different flux densities. However, within the range of flux density $0.1 \text{ T} \leq B \leq 1.1 \text{ T}$, the THD₁ of magnetizing current for both combined cores are comparable but the magnetizing current for $B > 1.1 \text{ T}$ in the case of combined SiFe+Nano core is less distorted than for the SiFe+NiFe core.

V. CONCLUSIONS

For the combined core SiFe+Nano the peak flux density values in magnetization curve are higher for the same values of magnetizing field than for the SiFe+NiFe core and this reduces the measurement errors in middle voltage current transformers. The bulk relative permeability of combined SiFe+Nano core is much higher than in the case of SiFe+NiFe magnetic circuit, which increases the output voltage of current transformers.

The selection of materials for combined magnetic circuits of middle voltage current transformers should be based not only on the magnetization curve and relative permeability values, but also on total harmonic distortion of magnetizing current.

Total harmonic distortion in relation to peak flux density values indicate that the cores combined from SiFe and Nano offer best applicability in terms of the distortion, range of operational flux density, and price.

The Characterisation of NiFe Cores for High Current Micro-inductors.

B. Jamieson, T. O'Donnell, N. Wang, J. Godsell, S. Roy
Microsystems Centre, Tyndall National Institute, Cork, Ireland

There is considerable interest in the integration of micro-inductors either on-chip or into the package, for application in switch mode power supplies for use in hand held electronic applications. For micro-inductors which are to be used in power converters, the inductor excitation current typically consists of a triangular waveform superimposed on a dc current. To increase the power handling of these inductors it is therefore important to understand their operation under dc-bias currents. In recent years there has been significant research into the integration of micro-inductors [1 - 3], however the majority of these were confined to low dc currents of less than 1 A. A few other devices with 'V' groove conductor and magnetic core design, have been demonstrated with current-carrying capabilities from 2.1 A up to 10 A [4, 5], although the width of the conductor which directly contributes to current handling ability has been increased for the higher current rating at the cost of inductances achieved. These 'V' groove inductors employ Co-Zr-O film as core materials deposited in a magnetic field using RF sputtering technique. While sputtering is a slow deposition technique which works well for deposition from nanometer up to a micrometer length scale on a relatively flat surface, we have demonstrated [6] deposition of a particular ferromagnetic alloy composition with uniform thickness even on a vertical side-wall using pulse-reverse electroplating technique. In this work we investigate the extension of the current handling to currents above 1 A for an one turn inductor structure with a wrapped around Ni45Fe55 core deposited in an uniaxial magnetic field of 200 Oe by pulse-reverse (PR) electroplating and the role which the shape of the inductor core play in increasing the maximum current. We are investigating the shape anisotropy effect on current handling capability further using micro-magnetic simulation of our fabricated inductor core structure.

Various inductors have been fabricated with the aim of characterizing the performance of the magnetic core under different dc bias conditions. The cross-section of a single turn inductor is shown in fig. 1. These inductors consist of a single copper conductor, $200\ \mu\text{m} \times 33\ \mu\text{m}$ in cross-section and surrounded by a layer of magnetic material to form a closed core. The core consists of a $6\ \mu\text{m}$ thick layer of Ni45Fe55, which is deposited by PR plating. The inductance was measured as a function of dc-bias current in the range from 0 A to 3 A. The graph in figure 2 shows a typical measurement of these devices normalized to zero bias fields.

It is well known that the shape can contribute to the anisotropy field of the core [7]. According to the analysis where the film is assumed to be homogenous the demagnetizing field is assumed to be affected by the shape of the device. As a result, the saturation field in the measured devices is much larger than the saturation of as-deposited Ni45Fe55. The effects of core shape are studied to determine the extent of the saturation enhancement and its effects on bias current capacity in the devices, in order to suggest designs to enhance bias capacity for next generation power inductors.

Closed magnetic flux configurations such as vortices have been studied to achieve higher density by limiting interaction between elements [1, 2]. Waeyenberge et al. have already experimentally observed switching of vortex core magnetization using a magnetic field [3]. However, controllable switching of the vortex chirality, which refers to the counter-clockwise (CCW) or clockwise (CW) rotation of the in-plane magnetization, is desirable. The authors have previously simulated spin-polarized current switching of vortex configuration in a 100 nm diameter Co/Cu/Py spin valve pillar [4]. An 8x8 spin valve array based on the simulated spin valve structure was fabricated to experimentally prove the simulated results. In this paper, the 8x8 spin valve array was characterized for MR signal using magnetic field switching.

Electron beam (e-beam) evaporation was used to deposit the following stack onto a SiO₂ wafer: Ti(10)/Py(10)/FeMn(10)/Co(20)/Cu(4)/Py(6)/Ti(2) thickness in nm. Photolithographic patterning and ion milling were used to shape the entire stack into the bottom electrode. Once the bottom electrode was formed, e-beam lithography and ion milling were used to pattern 8 x 8 array of Py/FeMn/Co/Cu/Py/Ti pillars into the spin valve structure on top of the bottom electrode. Then, the structure was planarized using SiO₂ deposited with an e-beam evaporator and a liftoff process. Finally, e-beam evaporation, e-beam lithography, and ion milling were used to shape the top Cu electrode. After fabrication of the array, the array was characterized using a four point probe MR tester.

The fabricated 8x8 array consists of thirty eight 100 nm pillars, eight 200 nm pillars, eight 300 nm pillars, eight 400nm pillars, and two 5 μ m pillars as shown in Figure 1. Inset in Figure 1 represents a typical SEM of two 5 μ m pillars. Figure 2 shows examples of magnetic field switching MR signal observed from a 100 nm pillar. In Fig. 2(a), one finds that the magnetoresistance decreases by applying in-plane external magnetic field, while a maximum MR value is found at zero field. This result implies that the initial vortex configurations in Py and Co layers have opposite chiralities, in which the in-plane magnetizations in both layers are antiparallel at their remanent state. With increasing magnetic field strength the vortex configuration with antiparallel chiralities in Py and Co layers is distorted, and this leads to decrease of the magnetoresistance. We note that for about half of the pillar structures MR measurements reveal the curves with the minimum value of the magnetoresistance at zero applied field (Fig. 2(b)), while the application of external magnetic field leads to the increase of MR. This is attributed to the same chiralities of the in-plane magnetization of the initial vortex configuration in Py and Co layers. For these pillar structures the initial in-plane magnetizations of NiFe and Co layers are parallel, and it leads to a minimum magnetoresistance at remanence. In this case the application of external magnetic field leads to small changes of the magnetoresistance.

In conclusion magnetoresistance experiments are conducted with arrays of multilayered NiFe/Cu/Co nanopillars with varying diameter as small as 100 nm. The results imply that the chirality in the NiFe layer effectively changes the magnetoresistance values. The result suggests a new

way to implement the vortex chirality in memory device applications, in which vortex states with controllable chirality switching in a layer of magnetic nanoelement may be used as memory bits

The first 2 dimensional (2D) images of Giant Magnetoresistance (GMR) using an infra red (IR) camera in the wavelength regime 8-12 μm are presented, demonstrating a factor of 3 improvement in sensitivity of the technique compared to previous work in the 3-5 μm regime.

In the far IR, the dielectric response of a metal is directly related to its d.c. electrical conductivity with the result that the refractive index is a function of the electrical resistivity. This is exploited in remote techniques for measuring GMR by sensing a change in reflection, transmission or emission in an applied magnetic field. Emissivity lends itself to spatial resolution using an IR camera to generate images of a material's apparent temperature. A change in emissivity due to an applied magnetic field results in a change in IR power radiated from the material's surface, which is observed as a change in the temperature. IR imaging techniques thus allow 2D images of GMR to be constructed. This has been demonstrated for GMR and spin-valve multilayers down to a resolution of 30 μm [1,2].

Assuming perfect thermal coupling between sample and detector, in the long wavelength Hagen Rubens region the GMR is proportional to the fractional change in emissivity, ϵ , i.e. $(\Delta\epsilon/\epsilon) = \gamma \times \text{GMR}$ with a correlation factor $\gamma = 0.5$. This dielectric model breaks down at shorter wavelengths where interband transitions become possible. This is seen in the magnetorefractive effect (MRE) spectrum in Fig. 1 in which the percentage change in the reflected intensity in an applied magnetic field is plotted as a function of wavelength. At long wavelengths the MRE tends to the Hagen Rubens value, whereas at short wavelengths the effect becomes smaller and changes sign. The wavelength regimes of the 2 cameras are indicated, showing a larger effect and different sign for the 8-12 μm band. Further improvement is expected due to better matching of the spectral sensitivity of the camera and the Planck radiation curve. Over the reduced wavelength band, Stefan's Law must be modified to: $I \approx \epsilon_{\text{avg}} \sigma' (T^x - T_0^x)$, where I is the radiated intensity, σ' is a modified Stefan-Boltzmann constant, T is the sample temperature (typically 320K), T_0 the temperature of the environment and x the power to which T is raised, 4 when integrating over the entire spectrum. New values of σ' and x are found by simulation. The value of σ' does not affect the measurement, but the reduction in x from 9.4 in the 3-5 μm range to 4.4 in the 8-12 μm range improves the sensitivity. In practice, the sensitivity is reduced relative to its ideal value by ambient radiation which is field-independent, but the response remains proportional to the GMR.

A NiFeCr/[(CoFe_{1.5nm}/Cu_{1.2nm})₂₅/TaN_{7nm}] antiferromagnetically coupled multilayer exhibiting 28% GMR in an applied field of 0.87T (provided by Seagate (Ireland)), was used to compare the 2 wavelength regimes. The correlation factor, γ , was found to increase in magnitude from 0.064 with the 3-5 μm camera to 0.2 with the 8-12 μm camera, with the sign of the effect reversing as expected. This corresponds to an apparent temperature drop of 0.6K in the applied field, easily detectable with the IR camera (resolution: 30mK). Fig. 2 shows the change in colour of the 2D temperature image as the magnetic field is applied giving a very visual image of the spatial variation of GMR across the sample. Note that this image has not been optimised for spatial resolution, but provides an indication of the potential of the technique for whole GMR wafer scanning.

The change in reflected intensity for a NiFeCr/[(CoFe_{1.5nm}/Cu_{1.2nm})₂₅/TaN_{7nm}] multilayer in an applied magnetic field of 0.2T. The shaded wavelength bands correspond to the wavelength sensitivity bands of the two IR cameras under test.

Thermal images of the giant magnetoresistive 5cm wide NiFeCr/[(CoFe_{1.5nm}/Cu_{1.2nm})₂₅/TaN_{7nm}] multilayer showing the apparent temperature change as the magnetic field is reduced from 0.87T to 0T. This apparent temperature rise results from the increase in emissivity as the electrical resistivity is increased. The images are taken using an InfraTec/Jenoptik Varioscanner 3021 IR camera sensitive to wavelengths from 8-12 μm , the sample was heated to T=315K.

Magnetic degradation of GMR spin-valve multi-layers due to electromigration induced failures.

J. Jiang¹, S. Bae¹, H. Ryu²

1. Electrical and Computer Engineering, National University of Singapore, Singapore, Singapore; 2. IT Convergence & Components Laboratory, ETRI, Daejeon, South Korea

Introduction

Ferromagnetic(FM)/Cu spacer/FM GMR spin-valve multi-layers have been paid a great deal of attractions in the various spintronic devices such as magnetic recording read sensors and magnetic random access memories (MRAMs) due to their technical promises. The most important consideration in designing such spintronic devices is the magnetic stability of spin-valve multi-layers[1]. In this study, magnetic degradation of GMR spin-valve multi-layers was investigated for the first time by considering the electromigration(EM) induced inter-diffusion between the magnetic layer and Cu spacer. In order to clearly verify the physical nature for the magnetic degradation of GMR spin-valve multi-layers caused by EM, a Co diffusion barrier was used to control the Ni-Cu intermixing through NiFe/Cu interfaces in the NiFe/(Co)/Cu/(Co)/NiFe multi-layer based spintronic devices. In addition, diffusion behavior of Cu and its physical effects on the magnetic degradation in the spin-valve multi-layers with or without Co diffusion barrier were characterized by using a EDX(Energy Dispersive X-ray) and a cross sectional TEM(XTEM).

Experiment

All the NiFe(3.0)/Cu(x)/NiFe(3.0)[nm] and NiFe(2.5)/Co(0.5)/Cu(x)/Co(0.5)/NiFe(2.5)[nm](x=1.8~3.2nm) spin-valve multi-layers were sputtered at the base pressure around 2×10^{-8} Torr. Ar working gas pressure for NiFe, Co and Cu thin films was fixed at 2 mTorr. To study the effect of EM-induced failures (EIFs) on the magnetic stability of NiFe/(Co)/Cu/(Co)/NiFe multi-layers, M-H loops before and after applying DC constant electrical stress were measured by using a vibrating sample magnetometer(VSM). All the samples were stressed under $J=1 \times 10^6$ A/cm² for 12 hours and their resistance change(ΔR) was measured using a computer-controlled probe station. The Ni-Cu interdiffusion at the NiFe/Cu interfaces was qualitatively analyzed using a nano-beam EDX with a nominal beam size of 2 nm and XTEM.

Results and Discussion

Figure 1 shows the M-H loops of NiFe/(Co)/Cu/(Co)/NiFe spin-valve multi-layers before and after electrical stress. As clearly shown in Fig.1-a and b, NiFe/Cu/NiFe showed an obvious change of magnetic moment and interlayer coupling field, while there was no magnetic degradation in NiFe/Co/Cu/Co/NiFe multi-layers. Fig.1-c shows ΔR during 12-hour electrical stress time. For the NiFe/Cu/NiFe tri-layers, resistance-time(R-t) curve showed a very serious oscillation characteristics (alternant electrical open and short), but in contrast, R-t curve showed continuous and smooth increase without any oscillation for the NiFe/Co/Cu/Co/NiFe multi-layers during electrical stress. By considering the relatively lower activation energy of Cu compared to that of NiFe and Co[1] and "current sinking effects"[2] describing 2/3 of applied current flows through Cu spacer due to film resistance difference, EIFs can be supposed to be first occurred in Cu spacer and then the melted Cu atoms would disperse through NiFe/Cu interfaces for intermixing with Ni atoms to form a Ni-Cu alloy (or non-magnetic Ni-Cu dead region) due to the high solid solubility between Ni and Cu atoms[3]. This would cause the decrease of magnetic layer thickness and accordingly result in the increase of "effective" spacer layer thickness. As a result, for the NiFe/Cu/NiFe, the interlayer coupling oscillation curve was seriously changed to shift toward the increasing direction of Cu spacer thickness after electrical stressing and the magnetization of NiFe/Cu/NiFe was dramatically

reduced due to the decrease of magnetic moment in NiFe magnetic layer. EDX analysis shown in Figure 2 apparently demonstrates that the inter-diffusion of Cu through the NiFe/Cu interfaces in the NiFe/Cu/NiFe spin-valve multi-layers is quite serious, while the insertion of Co thin film between NiFe and Cu layer shows a significant diffusion barrier effect. In conclusion, it was clearly verified that the control of Cu spacer inter-diffusion due to electromigration is the most crucial factor in determining the magnetic stability in GMR spin-valve multi-layer based spintronic devices.

[Introduction]

The point-contact Andreev reflection (PCAR) enables the direct measurement of the spin polarization in electron transport, which is one of important factor responsible for the magnetoresistance effect in various layered magnetic structure. The study on spin polarization is not only essential for better understanding of magnetic transport physics, but the wide application range of magnetoresistive devices makes it technologically relevant as well^{1, 2)}. We tried to develop a suitable ferromagnetic material for CPP-GMR. Full metals system is needed because it is so important in application for MR heads sensor to obtain large change of resistance in the active area, while maintaining a low resistance in the total system. Moreover, in the case of an epitaxial system, more ideal surface is able to be obtained than in the case of a polycrystalline one. Therefore one would expect it to be easier to investigate the physical origin of spin scattering in the active area than in that of a polycrystalline one in which the moment direction exerts various effects in the unit area. We attempted to prepare samples incorporating an artificially AML [Fe/Co]_n epitaxial film with ordered structure and to confirm the magnetic and structural properties of AML [Fe/Co]_n epitaxial films on MgO (001) substrate by PCAR, STM and RHEED³⁾. For the sake of comparison, we also prepared the pure Fe, and Fe₅₀Co₅₀ alloy epitaxial films.

[Experimental]

We prepared ordered phase Fe₅₀Co₅₀ by the alternate monatomic deposition method, in which monolayer of Fe and Co is alternately deposited at suitable substrate temperature^{4, 5)}. The samples were prepared on MgO substrates with orientation (001) by the EB evaporation technique. To examine the structure of the deposited epitaxial films, we used in-situ STM to observe their topology and in-situ Reflective High Energy Electron Diffraction (RHEED) technique to investigate epitaxial property of their surface. We prepared the samples with ordered or disordered epitaxial phase Fe₅₀Co₅₀ epitaxial layer on MgO (001) substrate by the alternated monatomic deposition of Fe (99.99 %) and Co (99.99 %) targets or the normal deposition of Fe₅₀Co₅₀ alloy target. The growth of an epitaxial film with 71 MLs (Monolayers) of [Fe/Co] on MgO (001) was performed at the substrate temperatures of 75 and 250 °C and a typical base pressure of less than 10⁻⁷ Pa. The disordered Fe₅₀Co₅₀ and pure Fe were fabricated at a substrate temperature of 75 °C, with thickness of 10 nm corresponding to that of the 71 MLs of AML [Fe/Co] epitaxial film. We present the PCAR measurements of X/Nb contacts, where X = bcc-Fe, Fe₅₀Co₅₀, and alternate monatomic [Fe/Co]_n. The PCAR measurements were done using an Nb tip, pressed into the metal films by a differential screw mechanism. A 0.3 mm diameter Nb wire was electropolished to a sharp needle with a tip diameter of approximately 100 nm, which was used to obtain the superconducting point contacts with the samples. The tip and film were enclosed in a jacket and immersed in a liquid helium bath. All measurements were performed at a temperature of 4.2 K. The normalized conductance curves were fitted with the modified Blonder-Tinkham-Klapwijk (BTK)⁶⁾ model to estimate the spin polarization P using a multiple parameter fitting. The dimensionless interfacial scattering parameter Z, superconducting gap Δ, and P were the parameters used for the fitting.

[Result and discussion]

The Andreev reflection at the [Fe/Co]_n/Nb point contact was used to determine the spin polarization of single-crystal films made by electron beam evaporation. From these measurements an intrinsic transport spin polarization P values of 0.48, 0.50 and 0.60 were obtained for pure Fe, Fe₅₀Co₅₀ alloy and alternate monatomic [Fe/Co]_n epitaxial film, respectively (Table 1). Moreover we confirmed that the spin polarization is affected by the substrate temperature (0.60 for 75 °C, 0.57 for 250 °C) and is higher for AML [Fe/Co] epitaxial film than for Fe₅₀Co₅₀ alloy, due to the increase in the degree of ordering for Fe₅₀Co₅₀ afforded by the monatomic deposition method. It should be noted that the P of 0.60 is equivalent to the value obtained by PCAR for half metallic heusler alloys⁹⁾. These results are of importance in understanding the physical origin of spin transport in all metal CPP epitaxial systems.

The antiferromagnetic coupling of the moments is due to the oscillatory exchange coupling phenomenon which reported by Parkin [1]. Several non-magnetic transition metals spacer layer such as Cr, Cu and Ru have stimulated considerable interest [2-4]. Because Os has very high melting and boiling point, which is predicted to have good effect on preventing interdiffusion between layers, and the disordered FePt is a very soft ferromagnetic material. In this investigation, we attempt to study on the effect of the Os layer to the FePt layers. The FePt/Os/FePt thin films were deposited on Si(100) substrates with a 5 nm Ta buffer layer by dc-magnetron sputtering system. The thickness of the ferromagnetic layers was 100 Å in all cases and a series of trilayers with Os spacer varied from 0 Å to 9 Å. The crystal structures were characterized by X-ray diffraction and high resolution transmission electron microscopy. Magnetic properties of the films were measured by a vibrating sample magnetometer. The magnetoresistance were measured with a standard dc four-point probe technique. We dealt with the FePt multilayer thin films without post annealing on purpose to achieve that the magnetism of FePt/Os/FePt thin films could be tend to appear an antiferromagnetic exchange coupling (AFC) behavior. Fig. 1(a) shows the hysteresis loops vs Os spacer thickness varied from 0 to 9 Å. As the thickness increased from 1 to 3 Å, it appeared an AFC behavior. The ferromagnetic behavior observed in samples with Os spacer layer of 0, 4, 5, 7 and 9 Å. In general, the AFC in multilayer system shows the first maximum of AFC peak occurring at spacer thickness between 8 and 11 Å for most spacer materials [5]; however, in FePt/Os/FePt films, it appeared at 2 Å. In our investigation, a clear AFC behavior of the FePt/Os/FePt system could be observed at 2 Å. From the M-H loops, the coercive force (H_c) of about several tens of oersteds was found which indicated that the FePt has a disordered structure. The results showed the squareness value decreased from 0.77 to the minimum value of 0.04 at 2 Å, and then increasing and dependence of saturation field on Os spacer layer thickness showed a maximum value of 2614 Oe at 2 Å as shown in Fig. 1(b) and 1(c), respectively. The anisotropic magnetoresistance is always existed in FePt multilayer system, even for samples with the Os thickness of 2 Å, i.e. for sample with strongest antiferro-magnetic coupling. Fig. 2(a) shows the variations of the ΔMR ratio with Os layer thickness. The measurements have been made with the magnetic field in the film plane and parallel to the current direction. The ΔMR ratio was defined as shown in the inset figure (ΔMR ratio = $100(R_p - R_o)/R_o$), that R_p is the peak value of resistance due to interlayer exchange coupling. From the MR study, ΔMR ratio increased from 0.01 % to the maximum value 0.14 % at 2 Å and then decreasing. The peak field of MR figures increased from 10 Oe to the maximum value 250 Oe at 2 Å and then decreasing as shown in Fig. 2(b). The FePt/Os/FePt thin films with Os layer varied between 1 and 9 Å were investigated. This is the first time that a clear AFC behavior of the FePt/Os/FePt system could be observed for samples with Os at 2 Å. The microstructure and details of the FePt/Os/FePt thin films will be discussed.

Novel Granular Thin Film Device Structure.

S. Regunathan, V. Ng

Information Storage Materials Laboratory, Dept of Electrical and Computer Engg, National University of Singapore, Singapore, Singapore

Granular thin films consist of nanometer size magnetic particles dispersed in non-magnetic insulating material[1]. The magnetic particles are super-paramagnetic with low coercivity(H_c) and their electrical properties are characterized by the phenomenon of Tunneling Magnetoresistance(TMR)[2]. Though many works have been carried out, the research on granular film devices is very limited, most common being the Granular in Gap structure [3].

In this paper a novel granular film device structure is proposed which consists of a insulating HfO_2 layer sandwiched between two granular film layers. The granular film used in our experiment consists of Co particles embedded in HfO_2 matrix. This structure is fabricated and investigated for possible tunneling of electrons between the top and bottom layer which may enhance the magnetoresistance (MR) properties.

The thin films are fabricated on Si and glass substrates by sequential sputtering of discontinuous layers of Co and HfO_2 . A thickness of 19nm (Fig.1a) is found to be optimum for the granular film in terms of H_c and MR ratio. Fig.1b shows the proposed structure whereby 2 layers of granular film are separated by a HfO_2 layer (9.3nm) and fig.1c shows the 38nm granular film reference. The granular film sputtered on Si and glass substrate are used for VSM and MR measurements respectively. Shadow mask technique is used to deposit Al contacts on the the glass substrate to facilitate MR measurements. The distance between the two contacts is 8mm.

Table 1 shows the H_c , saturation magnetization (M_s), magnetic retentivity (M_r) and squareness (S) obtained for the various structures. The proposed structure has a effective thickness of 38 nm for the granular film, but the H_c value is closer to that of the 19nm thick structure. This clearly indicates that, there is minimal magnetic coupling between the top and bottom granular film in the proposed structure.

Fig.2 shows the MR measurements for all the three structures. A constant dc current of 1 μ A is sourced and the corresponding voltage is measured in order to get the resistance. This measurement is carried out while sweeping the DC magnetic field from +4.2 KOe to -4.2 KOe and then back to + 4.2 KOe. The MR ratio is calculated as $(R_{max}-R_{min})/R_{min}$. It can be seen that the 38nm thick structure has the highest resistance (697.71K Ω), followed by the 19nm thick film (322.94K Ω) and the proposed structure (55.24K Ω). As far as the MR measurement is concerned the 19nm structure gives the highest MR ratio for the entire range followed by the proposed structure and then the 38nm structure.

However, closer analysis of the graph shows that the change in gradient is the highest for the proposed structure. In order to get a clear picture and to eliminate the confusion caused by the different resistance ranges for the 3 structures, MR ratio vs. Magnetic field graph has been plotted (Fig 3). It can be clearly seen that the proposed structure is more sensitive to the magnetic field variations in the range 0–3000 Oe, whereas for fields greater than 3000 Oe, the 19nm structure gives a better sensitivity. This variation could be due to the fact that there is tunneling occurring between the top and bottom layer of the proposed granular film structure and its contribution is more apparent at lower fields than at higher fields. Currently, lateral devices based on this structure are being fabricated, the dimensions of which are in the nanometer regime. The results for the same will be included during the final article submission.

Nature and entropy content of the magnetic transitions in pure and pseudo-binary Laves phases RCo_2

M. Parra-Borderías¹, F. Bartolomé¹, J. Herrero-Albillos², L. M. García¹

1. Instituto de Ciencia de Materiales de Aragón, CSIC-Universidad de Zaragoza, Zaragoza, Spain; 2. Department of Materials Science, University of Cambridge, Cambridge, United Kingdom

RCo_2 Laves phases compounds (R= rare earth ion) are potential candidates for magnetic cooling [1] in the 30-150 K temperature range, due to their abrupt magnetization change in a narrow temperature range. As compounds displaying first-order phase transitions are more interesting for magnetocaloric applications, the determination of the thermodynamic order and the entropy content of RCo_2 magnetic transition is of great interest.

The first aim of this work is the systematic study of the nature of the magnetic ordering in five RCo_2 pure compounds (R = Er, Dy, Ho, Nd, Pr) [2] and in the pseudo-binary solid dilution $\text{Er}_x\text{Pr}_{1-x}\text{Co}_2$ ($x = 0.9, 0.8, 0.7, 0.6, 0.4$) by using the Banerjee criterion [3], and analysing its application limits at the same time. According to this criterion, developed in the framework of the Landau-Lifshitz theory, one can distinguish first- and second-order phase transition analysing the parameters sign in the expression that relates magnetization and magnetic field [3]:

$$\mu_0 H = a(T) \times M + b(T) \times M^3 + c(T) \times M^5 \quad (1)$$

To do so, we have systematically measured $M(H)$ isothermal curves in all studied systems, as shown in Fig. 1 for R = Er and Dy. The application of Banerjee criterion to $M(H, T)$ measurements on RCo_2 Laves phases, by fitting the curves as shown in Fig. 2, confirms the second-order character of the transition in PrCo_2 and NdCo_2 , which was recently questioned [4]. Moreover, this study shows a “weakening” of first-order character in $\text{Er}_x\text{Pr}_{1-x}\text{Co}_2$ ($x = 0.9, 0.8, 0.7$) solid dilutions as we diminish x , in the same way as DyCo_2 is *weakly* first-order, i.e. the discontinuity of first derivatives of thermodynamic potentials are very small. We will show that the thermal dependence of the Landau-Lifshitz parameters near the transition allows to define a new parameter, Δ , that quantifies the “strength” of the transition first-order character; this parameter can be phenomenologically related to the entropy change in the transition.

For $\text{Er}_x\text{Pr}_{1-x}\text{Co}_2$ ($x = 0.6, 0.4$) a competition between ferromagnetic Pr-Co interaction and antiferromagnetic Er-Co interaction is observed as low-field reorientations in $M(H, T)$ measurements. This process is studied by means of calorimetric and susceptibility measurements.

Finally, we present magnetocaloric parameters of RCo_2 compounds obtained applying Maxwell relations. The interest of pseudobinaries is mainly to combine the high critical temperature of some members of the series (as GdCo_2) and the very high entropy content of the first order transition of others (as ErCo_2) in order to tune the properties of the final system. We will present our results on the expectable results on this strategy.

Estimating magnetic entropy change by a mean-field scaling method and the effect of magnetic irreversibility in first-order transitions.

J. S. Amaral¹, N. O. Silva^{1,2}, V. S. Amaral¹

1. Physics and CICECO, Universidade de Aveiro, Aveiro, Portugal; 2. Materia Condensada, Facultad de Ciencias, Zaragoza, Spain

Magnetic refrigeration is an ecologically friendly alternative to vapor-cycle refrigeration. A magnetic refrigeration device is based on cycles of magnetizing and demagnetizing a magnetic material, making the study of the magnetocaloric effect of materials a very active field of research [1]. The magnetocaloric effect can be characterized from two distinct thermodynamic values, the adiabatic entropy change, ΔT_{ad} (from calorimetric measurements) and ΔSM (from calorimetric or magnetization measurements) [3]. The standard method for estimating ΔSM from magnetization measurements is to numerically integrate a Maxwell relation.

In a recent work [3], we presented a method based on mean-field theory, where directly from magnetization data, the mean-field exchange parameter λ and the state function f , from the equation of state $M=f(H+\lambda M)/T$, are determined.

Having determined λ and f , magnetic entropy change can be estimated from numerically integrating the inverse f function in M , if λ does not explicitly depend on T . Taking experimental measurements from second- and first-order manganite systems, magnetic entropy estimations from the Maxwell relation integration were found to be comparable for both systems:

In the case of the first-order manganite, we found that if the M versus H data generated by the mean field method was used to estimate ΔSM via integration of the Maxwell relation, an extra peak would appear near T_C , very similar to experimental results obtained in first-order magnetic transition systems, and generally attributed to numerical errors [4]. However, the extra ΔSM peak from integrating the Maxwell relation persists even with arbitrarily small steps in T and H , which would minimize the numerical error, indicating that its presence has another origin. On the other hand, integrating the inverse f function produced curves with no extra ΔSM peak.

In order to better understand this effect, we modeled the results of measuring $M(H)$ in non-equilibrium conditions in 1st order phase transitions, by the mean field model. The non equilibrium solutions correspond to situations of measurements in decreasing and increasing fields near the phase transition. The calculated values (together with the equilibrium solution) of $M(H)$ at each temperature were used as input for the determination of the magnetic entropy change using the Maxwell relation. The state function used was the Brillouin function with $S=2$, and the exchange parameters chosen where a λ value corresponding to a $\theta_p \sim 300$ K, and $\lambda^3 = 1.5$ (Oe.g.emu⁻¹)³ (Figure 1).

Estimating the magnetic entropy change from the inverse Brillouin function for the three curves produced similar results, while using the Maxwell function for the three solutions gave far different results, whereas only in equilibrium are the two methods in agreement (Figure 2).

The amount of overestimation of ΔSM by Maxwell relation integration in out-of-equilibrium conditions depends on how strongly first-order is the character of the transition, and can clearly exceed the limit of $R \ln(2S+1)$ for a large value of λ^3 . For the same set of data, estimating ΔSM by the inverse Brillouin integration never exceeds this limit.

Magnetic and structural phase transitions in magnets with a NaCl structure.

F. A. Kassan-Ogly¹, B. N. Filippov²

1. Department of Theoretical and Mathematical Physics, Institute of Metal Physics, Ekaterinburg, Russian Federation; 2. Lab. of Micromagnetics, Institute of Metal Physics, Ekaterinburg, Russian Federation

A vast experimental material is available now for magnetic structures and properties of ferromagnets and antiferromagnets with a NaCl structures called monpnictides and monochalcogenides (UN, HoP, CeBi, EuS, UTe, GdSe and others). These antiferromagnets possess very peculiar features that did not obtain the adequate explanation within the framework of existing theoretical models and approaches. In particular, a wide variety of changing magnetic structures with varying temperature and magnetic field, coincidence of magnetic and structural phase transitions (of the first order, as a rule), very strong anisotropy, very special diffuse magnetic neutron scattering above phase transition points, and so on. The main aims of the present paper are the derivation of possible magnetic structures in an fcc lattice with the nearest-neighbor and next-nearest-neighbor interactions taken into account, and the development of a theory of magnetic and other properties of such antiferromagnets. As the initial point, we use not the conventional Heisenberg model, but rather the models of utmost strong anisotropy, modified 6-state and 8-state Potts models [1]. Figure 1 shows possible directions of a magnetic moment in these models. For both models we constructed the sets of interrelated equations for multicomponent order parameter that connect the magnetic and structural properties of the system, and proposed algorithm for their numerical solution.

A revised derivation scheme of possible magnetic structures in an fcc lattice with the nearest and next-nearest-neighbor interactions taken into account is proposed.

Two new types of antiferromagnetic ordering are obtained in an fcc lattice (Fig.2) that can be useful to improve the identification of conventional and new magnetic structures in monpnictides and monochalcogenides. On the base of exchange energy minimization it is shown that some antiferromagnetic structures considered earlier are impossible to exist.

We also showed that at some values of the ratio of cation and anion radii magnetic ordering is impossible in magnets with a NaCl structure.

We derived the expressions for correlations functions and carried out numerical calculations of temperature evolution of neutron magnetic scattering in entire temperature region. It is shown that transformation of the high-temperature diffuse scattering into magnetic Bragg reflections in the Curie or Neel point is the mechanism of magnetic phase transition (Fig.3), and that detailed study of the high-temperature diffuse scattering allows one to get information on the forthcoming phase transitions and low-temperature magnetic structures.

The applications of the developed theory can be found in [2—5].

A first-order ferromagnetic-to-paramagnetic (FM-PM) phase transition is an atypical phenomenon normally associated to strong coupling among different degrees of freedom. In a ferromagnetic system, coupling between the magnetization, M , and other order parameters (or between M and some other non-ordering variable) can renormalize TC, and under certain circumstances change the order of the magnetic phase transition.[1]

Interestingly, many of the most exciting electronic/magnetic phenomena (large magnetocaloric response in ErCo₂, Mn_{1-x}Fe_xAs, field-induced structural transitions and magnetoresistance in MnAs, metamagnetism in CoS₂, etc.) appear close to a first order FM-PM transition.

The case of the itinerant ferromagnet CoS₂ is particularly interesting: TN is reduced with pressure, at the time that the transition becomes first order. However, replacement of S by Se causes a similar reduction of TN in spite of the volume increase; a first-order phase transition has also been suggested for a moderate amount of Se. These results indicate that Se is not just increasing the volume of the unit cell, but it is playing a more decisive role in the physical properties of the material.

In this work we will present experimental results of magnetization under pressure and magnetic fields at different temperatures to monitor the change in the nature of the magnetic phase transition. We derived the Landau coefficients of the phase transition and, contrary to previous suggestions, we found that the transition is first order (or nearly first order) in CoS₂, but becomes continuous after Se doping. However, at high fields a metamagnetic transition is observed in Se samples, and this could be the source of previously interpreted as a first order phase transition.

This result will be interpreted on the basis of thermodynamic model applicable to itinerant ferromagnets with strong spin fluctuations.

We will present also electronic transport, magnetoresistance, thermoelectric power, electron paramagnetic resonance, and high-pressure x-ray diffraction results on carefully synthesized samples in order to propose a new phase diagram for this family of compounds.

Magnetic anisotropy is one of the most important properties of magnetic materials and one of the most deeply investigated. As a consequence, the magnetization orientation along certain directions becomes energetically favored and the reversal (hysteresis loop) behavior depends on the applied field orientation. Hysteresis is the central feature of ferromagnetic materials below the Curie temperature and is the property that engineers exploit in practically all applications. Magnetization reversal processes and hysteresis reflect the responses of magnetization to applied fields, and thus they are fundamental to understand reversal mechanisms in nanomagnetism. During the last decades, epitaxial artificial structures represent model systems to study the influence of reduced dimensionality and symmetry on magnetic properties. For instance, the broken symmetry at surfaces and/or interfaces creates contributions to the magnetic anisotropy, leading to alter both magnetization easy-axes directions and reversal processes. The fundamental understanding and control of the phenomena is thus required in order to improve production methods and material quality. In this presentation we will give a general picture on the magnetic properties, including both characteristic magnetization axis directions and magnetization reversal processes, of epitaxial magnetic systems with broken symmetry.

We have chosen a well characterized system, γ' -Fe₄N(100) thin films, in which the four-fold crystal symmetry of the film is broken by a two-fold contribution, originating from stress relaxation of the films. Iron nitride films were grown on Cu(100) single-crystals by molecular beam epitaxy of Fe in the presence of a beam of atomic N provided by a radio-frequency plasma source. The mechanisms of growth were studied from the early stages up to 50 nm thick films by scanning tunneling microscopy (STM), low energy electron diffraction (LEED) and Auger electron spectroscopy. Under the appropriate growth conditions, the films are epitaxial and single-phase γ' -Fe₄N(100) [1]. The effects of symmetry breaking of magnetic anisotropy on magnetization reversal behaviour have been investigated by high resolution vectorial Kerr magnetometry. Angular dependent in-plane resolved hysteresis loops were acquired in the whole angular range every 1.8°, with 0.5° angular resolution. The magnetization reversal processes was determined by analyzing the loops by using both normal and vectorial representations (left and right graphs of Fig. 1a). In general, the reversal depends on the applied magnetic field angle and on the anisotropies involved. As expected for a thin film with four-fold crystal symmetry, the results show the existence of two easy and two hard magnetization axes. But, in this case, the easy axes are not orthogonal [2], the hard axes are not equivalent, the magnetization reversal behaviour around the two easy axes is not symmetric (see Fig. 1a), and the reversal behaviours of the two hard axes are not alike. As a consequence, the polar plot of the remanence displays a “butterfly” shape behaviour (see Fig. 1 b).

Numerical simulations based on a simple model have been used to address all the aforementioned features[3]. These features depend on additional terms of the magnetic anisotropy. For instance, the competition between the biaxial (four-fold) anisotropy and the additional uniaxial (two-fold)

anisotropy, is the key parameter which control these effects. On the basis of anisotropy balance, we show that the model is applicable to a variety of other symmetry-breaking systems, including other metals, semiconductors, and insulating magnetic materials, indicating why many of these effects were not reported before. The anisotropy constants (and thus the ratio between them) can be changed, for example, if another substrate, layer thickness, material, or temperature are employed. This fundamental understanding could be applicable in order to prepare magnetic materials with custom-chosen properties.

(a) In-plane resolved magnetization curves of a γ' -Fe₄N(100) film around one of the easy axes. Hysteresis (left graphs) and vectorial (right) plots reflect the non-symmetric behavior of the reversal around e.a.I. Upper (bottom) graphs show reversal governed by nucleation a propagation of 90° (180°) domain walls. (b) Polar plot of the remanence of the parallel component, i.e., $M_{||,R} = M_{||}(0 \text{ mT})$. The range of angles where different reversal behaviors are found are marked with different shaded areas, e.g., brighter areas indicates the angles where the reversal proceeds by two irreversible transitions (around h.a.II).

Cobalt doped β -peptide nanotubes: a new class of spintronic materials.

B. Sanyal¹, P. I. Arvidsson^{2,3}, O. Eriksson¹

Novel materials for use in spintronics applications are continuously sought after [1]. The attention is caused by the potential of manipulating the electron spin in semiconducting devices, which may offer an improvement compared to conventional charge controlled devices. Currently most of the attention is paid to diluted magnetic semiconductors (DMS) for which applications in e.g. non-volatile memories and smaller electronic components have been suggested. The main goal which this research strives for is to develop a ferromagnetic semiconductor which is operational at room temperature. In addition to DMS materials, other groups of materials are currently being investigated [2]. For instance, organometallic molecular materials have recently been under focus. A class of materials which have potential in this field are peptide nano-tubes (PNTs), and they are the focus of this work. An isolated peptide ring has 15 H, 9 C, 3 N and 3 O atoms, as shown in Fig.1, where the infinite nanotube is shown by stacking the peptide rings.

We report a density functional theory based *ab-initio* investigation of protein nanotubes formed by a stacking of β -peptide rings. The calculations were performed using the Vienna Ab-initio Simulation Package (VASP) [3] within the projector augmented wave method. We have optimized the structure of β -peptide rings arranged in a nanotube geometry. The calculated inter-atomic bond distances both by local spin density approximation and generalized gradient approximation are found to agree with observations as is the equilibrium inter-ring separation (4.8 Å). A significant energy gap of around 4 eV is present between the HOMO and LUMO (lowest unoccupied molecular orbital).

The electronic structure has been analyzed by calculating the density of states and band structures, which reveal wide bandgap semiconducting properties of the nanotube.

The possibility of doping β -PNT with transition metal atoms is found to be energetically possible, and Co doped β -PNT is found to be a strong ferromagnetic material with impurity states just below the conduction band edge. The interatomic exchange coupling for various transition metal atoms is shown in Fig.2. The important thing to note is that Co atoms couple ferromagnetically. The strength of the magnetic (exchange) coupling is quite strong for Co since the calculated energy difference between ferromagnetic and antiferromagnetic coupling is ~ 40 meV/atom. A mean field analysis, which is appropriate in the present case of strong neighboring magnetic atoms, reveal an ordering temperature of 350 K, which demonstrates an ordering temperature above room temperature. The total magnetic moment of the unit cell with 2 Co atoms is $2.00 \mu_B$, an integer value which is the signature of half-metallicity. From the analysis of the projected charge and magnetic moment inside the Co atomic spheres, one notes that Co has around 4 and 3 d-electrons in the spin-up and spin-down channels respectively yielding a magnetic moment of about $1 \mu_B$.

Finally, we have calculated the formation energy of the impurity Co atom in the β -PNT host. The calculated formation energy is around 3 eV signifying the fact that the energy cost of creating Co impurities in β -PNT is similar to the energy cost of impurity doping of conventional semiconducting materials. This makes Co doped β -PNT a very good potential candidate as an β -doped material in spintronics applications.

Calculated energy difference between ferromagnetic and antiferromagnetic alignments of transition metal atoms in β -PNT. Values below zero indicate that ferromagnetism is preferable.

Magnetotransport Properties of $\text{Y}_2\text{Fe}_{17-x}\text{Co}_x$ Single Crystals.

J. Stankiewicz¹, K. P. Skokov², A. G. Khokholkov², J. Bartolomé¹, Y. G. Pastushenkov²
 1. Instituto de Ciencia de Materiales, CSIC - Universidad de Zaragoza, Zaragoza, Spain; 2. Faculty of Physics, Tver State University, Tver, Russian Federation

Fe-rich intermetallic compounds such as $\text{Y}_2\text{Fe}_{17-x}\text{Co}_x$ are attractive for use in magnetic cooling. Y_2Fe_{17} is a natural multilayer system in which the Fe layers (perpendicular to the c axis) are intercalated with dumb-bell Fe pairs. This weak ferromagnet shows a large planar anisotropy below its ordering temperature of 320 K. When Co is substituted for Fe in $\text{Y}_2\text{Fe}_{17-x}\text{Co}_x$ alloys, the easy-plane anisotropy prevails up to $x \leq 8$, where it changes to an easy axis one. There is experimental evidence for preferential site substitution of Fe by Co: Co atoms hardly substitute Fe at the dumb-bell sites till its content is over 60%.

In spite of the abundance of reports on the magnetic properties of $\text{Y}_2\text{Fe}_{17-x}\text{Co}_x$, we do not find any paper devoted to their electron transport properties. Here, we report results of electrical resistivity, Hall effect, and magnetization studies in single crystals of $\text{Y}_2\text{Fe}_{17-x}\text{Co}_x$ ($x \leq 4$). These measurements were performed in magnetic fields, up to 5T, and in a temperature range from 5 to 700 K. We find a large anisotropy in the Hall effect of $x \leq 2$ crystals that can likely be attributed to their layered structure and selective substitution.

The $\text{Y}_2\text{Fe}_{17-x}\text{Co}_x$ single crystals were grown using inductive melting. Their composition and orientation were checked by x-ray diffraction. All of the specimens show a hexagonal $\text{Th}_2\text{Ni}_{17}$ crystal structure. The low-field Hall resistivity ρ_{xy} (Fig. 1) is almost one order of magnitude larger for the easy magnetization direction ($H \perp c$) than for hard magnetization direction ($H \parallel c$) in Y_2Fe_{17} . It peaks close to T_c for both orientations. The temperature variation of magnetization is also shown in Fig. 1.

Phenomenologically, the Hall resistivity can be written as $\rho_{xy} = R_o B + R_s 4\pi M$, where R_o and R_s are the normal and anomalous Hall effect (AHE) coefficients, respectively; B is the applied magnetic induction and M is the spontaneous magnetization. In ferromagnetic materials $\rho_{xy} \approx R_s 4\pi M$. There is a simple relation between AHE and the longitudinal resistivity: $\rho_{xy} = a\rho_{xx} + b\rho_{xx}^2$. The first term represents the skew scattering component. The second term is brought about either by side-jump or intrinsic, independent of scattering, contribution to ρ_{xy} . All terms follow from spin-orbit coupling. The intrinsic contribution, which is related to Berry phase effects on conduction electrons, can be quite large. Coefficients a and b are usually linear in the magnetization for the above mechanisms. To separate the various contributions to the AHE resistivity, we plot $\rho_{xy}/(M\rho_{xx})$ vs ρ_{xx} as shown in Fig. 2. Below $\rho_{xx} \approx 90 \mu\Omega\text{cm}$ ($T \approx 150$ K), this plot is linear for $H \parallel c$ and independent of ρ_{xx} for $H \perp c$. This clearly shows that skew scattering entirely dominates AHE resistivity for electrical current flowing along the c axis, but it has almost no effect otherwise. Similar behavior is observed for $x=2$ compounds but not in $x=4$ samples. The Kondo-Maranzana model (Maranzana67) of d -orbit- s -spin interaction accounts satisfactorily for such behavior if the layered structure and preferential substitution in $\text{Y}_2\text{Fe}_{17-x}\text{Co}_x$ is taken into account.

On the other hand, both side-jump scattering and intrinsic contributions to the AHE resistivity give a variation which is quadratic in ρ_{xx} . We find this for $H \parallel c$ in all compounds studied. Their separation is not easy and requires the application of very high magnetic fields. The AHE is usually attributed to side-jump scattering when ρ_{xx} is large, as it happens in concentrated magnetic alloys. However, our rough estimate for this effect shows that it may account only for 20% of the observed variation. For the intrinsic (Berry phase) conductivity we obtain a value of $680 \Omega\text{-}1\text{cm-}1$ which is not too different from the value ($1032 \Omega\text{-}1\text{cm-}1$) found experimentally for bcc Fe.

In the last two decades, especially since the discovery of the Quantum Hall Effect, a lot of progress has been made in the study of two-dimensional electron systems, and very important and unusual properties have been discovered when these systems are subjected to external AC and DC fields. In the last years two experimental groups [1,2] have announced the existence of vanishing resistance in 2DES, i.e. zero resistance states, when these systems are under the influence of a moderate magnetic field (B) and microwave radiation simultaneously. In the same kind of experiments large resistivity oscillations have been observed [1,2]. In the same way, two decades ago a novel type of magnetoresistance oscillations, periodic also in $1/B$, was discovered by D. Weiss et al.[3]. In this case these oscillations are observed in high-mobility AlGaAs/GaAs heterojunction with a holographic induced lateral periodic modulation in one direction. In other words a superlattices is grown on a two-dimensional electron system.

Experimental results about the effect of microwave radiation on the Weiss magnetoresistance oscillations are not available yet. However it would be very interesting to get to know that effect: for instance if these oscillation can be modulated, quenched or even if zero resistance states can be achieved. These novel experimental results would represent a real challenge for the theoretical existent models for the transport through these heterostructures.

In these scenario that represent the Weiss oscillations we have developed a theoretical model based in a previous one carried out by the authors to study the recent experimental results [1,2] on zero resistance states and microwave-induced resistance oscillations [4]. This novel extension of the model is based in the effect that microwave radiation is able to cause on the scattering that electrons suffer with charged impurities. We propose that the electron scattering jump is modulated by the presence of microwave radiation and the final electron jump presents an interference behaviour between the effect of the superlattice and the effect microwave radiation. In our calculated results Weiss oscillations are modulated by microwave radiation presenting a pulse profile. The final profile presented by the magnetoresistance depends mainly on the spatial period of the superlattice and the frequency of the microwaves. Depending on the values of these parameters, the oscillations can reach zero resistance states (see Figure).

Nonlinear modulation of spin-orbit interaction in a semiconductor channel.

H. Koo¹, J. Kwon¹, J. Eom^{2,1}, J. Chang¹, S. Han¹

1. Center for Spintronics Research, Korea Institute of Science and Technology, Seoul, South Korea; 2. Department of Physics, Sejong University, Seoul, South Korea

Controlling spin-orbit interaction is essential part for the development of spin field effect transistor. The electric field generally induces the spin-orbit interaction in the high mobility system, while structural asymmetry of a quantum well shows the same phenomenon. If the quantum well asymmetry is linearly changed by electric field, the modulation of spin-orbit interaction is very simple. However, the electric field dependence of spin-orbit interaction shows non-linear relationship and it is determined by the structure of high mobility semiconductor system. Therefore, we have to decide the proper range of the gate voltage for an efficient modulation of spin-orbit interaction.

In this research, we utilize an inverted high electron mobility transistor (HEMT) structure with InAs channel [1, 2] to investigate the gate-controlled spin-orbit interaction. Figure 1 shows the vertical view and calculated energy diagram of the substrate. The inverted heterostructure, where the carrier supply layer is located below the quantum well, is grown by molecular beam epitaxy as shown in Fig. 1(a). In this system, the InAs channel is sandwiched by $\text{In}_{0.52}\text{Al}_{0.48}\text{As}$ / $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}$ double cladding layers. The quantum well shape is not symmetrical due to the carrier supply layer even without gate voltage as shown in Fig. 1 (b). Therefore the internal electric field arises and finally generate Rashba effect relative spin-orbit coupling.

Observing the Shubnikov-de Haas (SdH) oscillation at $T = 1.8$ K, we determined the gate voltage dependence of spin-orbit interaction parameter (α) and the carrier concentration (n_s). In order to measure SdH oscillation, the 2DEG strip is shaped by ion milling. The gate electrode was formed after depositing SiO_2 of which thickness is 100 nm. The channel resistance was measured in the external magnetic field perpendicular to the plane. As shown in Fig. 2, beat patterns arise because spin-up and -down electrons generate different oscillation frequencies, leading to beats when these two signals combine. Figure 3 shows that the spin-orbit interaction parameter decreases with increasing gate voltage but the gate voltage dependence of spin-orbit interaction parameter shows nonlinear relationship. When the minus gate voltage is applied, the slope of quantum well bottom becomes steeper and the more internal electric field is generated. In the case of applying plus gate voltage, the slope of quantum well tends to flat and the internal electric field becomes smaller. From our band calculation, however, for the same amount of applied voltage, the slope change induced by plus gate voltage is much smaller than that induced by minus gate voltage. The reason is that the carrier supply layer is located on the -z direction from the quantum well so that the slope of quantum well would not be flat and inversed. These simulation results agree with the experimental data of α in Fig. 3.

In conclusion, the spin-orbit interaction parameter is not linearly changed with gate voltage due to the non-linear quantum well reformation. This non-linear behavior is attributed to the asymmetric charge distribution of quantum well. From our experiment, the spin-orbit interaction strength is easily controlled in the range of $V_g < 0$ in an inverted heterostructure.

Ordinary Magnetoresistance of Individual Single-Crystalline Bi Nanowires.

J. Ham¹, D. Kim², W. Shim¹, J. Kim¹, K. Lee¹, W. Jeung², W. Lee¹

1. Department of Materials Science and Engineering, Yonsei University, Seoul, South Korea; 2. Division of Material Research, KIST, Seoul, South Korea

Semimetallic bismuth (Bi) has been extensively investigated over the last decade since it exhibits very intriguing transport properties due to their highly anisotropic Fermi surface, low carrier concentration, long carrier mean free path l , and small effective carrier mass m^* . The magnetoresistance (MR) behavior and long carrier mean free path l in Bi thin films are of particular importance, since they can be exploited for spintronic device applications such as magnetic field sensors and spin-injection devices. With respect to “spintronics”, it is expected that Bi can be used as a spin channel in a spin-injection device due to the very long spin diffusion length l_{sd} of a few ten μm , following the relation $l_{sd} = (l v_F \tau_{\uparrow\downarrow})^{1/2}$, where, v_F is the Fermi velocity and $\tau_{\uparrow\downarrow}$ is the spin relaxation time. In recent years, comprehensive studies have focused on Bi nanowires because of quantum confinement effect. Transport properties in Bi nanowires has been known to depend on the purity and the concentration of crystal defects since a distorted structure compromises the unusual electronic properties of Bi nanowires. Therefore, high crystal quality of Bi nanowires is crucial to investigate unique transport properties of Bi nanowires. In the present work, we report the magneto-transport properties of individual Bi nanowire grown by stress-induced method to prepare single-crystalline Bi nanowires.

Bi thin films were grown on a thermally oxidized Si substrate in a radio frequency (rf)-sputtering system with a Bi target of 99.999%. The deposition of Bi was carried out in a vacuum chamber with a base pressure of 5.0×10^{-7} Torr. Rf power of 100W and an Ar working pressure were utilized, yielding a growth rate of 32.7 Å/sec. For growth of the Bi nanowires, the sputtered-Bi thin films were transferred to a furnace for heat treatment at 270 °C for 10 hours. A representative 400-nm-diameter individual nanowire device was fabricated by a combination of photolithography, electron-beam lithography, and a lift-off process (see Fig. 1A).

Measurements of current versus voltage (I-V) show that the contacts were highly ohmic at 300 K, corresponding to resistivity ρ of $1.29 \times 10^{-4} \Omega\text{cm}$. Fig. 1B and 1C shows the variation of the transverse and longitudinal ordinary magnetoresistance (OMR) of a 400-nm-diameter Bi nanowire. The largest transverse and longitudinal OMR of 2496 % at $T = 110$ K and -38 % at $T = 2$ K in the individual 400-nm Bi nanowire were observed, which is more than 4-times larger than the largest OMR (35 K) of polycrystalline 400-nm-diameter Bi nanowires array grown by electrodeposition. Therefore we are indicating that the Bi nanowire grown by stress-induced method shows the longest mean free paths l , and high-quality, single crystalline. The effect of wire-boundary scattering arising from the reduction of the cyclotron radius caused by a high magnetic field parallel to the axes of cyclotron resonance, occurring in only a single-crystalline nanowire [1, 2] was also observed.

Associated with the crystal quality of the Bi nanowire, mean free path is directly related to the observation of Shubnikov-de Haas (SdH) oscillations. The oscillations masked by impurity scattering is characterized by an exponential decay, $\exp(-l/w_c \tau)$, where relaxation time τ is defined $\tau = el/m^*$, and the observation of robust SdH oscillations (see Fig.2) proves that the Bi nanowire is the high quality, single-crystalline. Our results suggest the possibility of exploring the underlying physics in individual high quality single-crystalline Bi nanowires.

The effects of spin relaxation on spin transfer switching of a non-collinear giant magnetoresistance device.

N. Chung^{1,2}, M. B. Abdul Jalil¹, S. Tan², J. Guo¹, B. AL Sundaram²

1. Information Storage Materials Laboratory, Electrical and Computer Engineering Department, National University of Singapore, Singapore, Singapore; 2. Spintronics, Media and Interfaces Division, Data Storage Institute, Singapore, Singapore

Slonczewski¹ and Berger² pointed out that when a spin polarized current passes perpendicularly through a non-collinear giant magnetoresistance (GMR) device, a spin torque is resulted due to the interaction between the itinerant electron spin and the local magnetic moment of the free layer. Spin torque persists as long as the itinerant spin remains unaligned with the local moment, which implies that spin diffusion length might have a crucial impact on the spin torque and the switching behavior of a GMR device. In this article, we revealed that the spin diffusion length in both free and spacer layers have non-negligible effects on spin transfer switching in a GMR device. Based on the theoretical groundwork of Zhang, Levy and Fert³, we investigated the effects of spin relaxation characterized by the spin diffusion length in these layers on the spin transfer torque (STT) and the areal resistance (RA) of a pseudo-spin-valve (PSV). We consider a typical $\text{Co}_{(\text{pinned})}$ -Cu- $\text{Co}_{(\text{free})}$ PSV with non-collinear magnetization, and analyze its spin transport at varying angular deviation θ between the free and the pinned Co magnetizations. The layer thicknesses in the PSV are set as $t_{\text{Co1}} = 10$ nm for $\text{Co}_{(\text{pinned})}$, $t_{\text{Cu}} = 6.5$ nm for Cu, and $t_{\text{Co2}} = 2.5$ nm for $\text{Co}_{(\text{free})}$. Our calculations revealed that an increase of $l_{\text{sf}}^{(\text{Cu})}$ in the spacer layer raises both the STT (Fig. 1a) and $R(\theta)$ (Fig. 1b) of the spin valve. However, a high probability of spin flipping in the spacer layer is found to be undesirable for spin transfer switching devices where a large spin torque is required, nor is it suitable for spin valve where a high MR ratio is required. The increase of STT and $R(\theta)$ with the increase of $l_{\text{sf}}^{(\text{Cu})}$ is not indefinite, but begins to saturate when exceeds $l_{\text{sf}}^{(\text{Cu})} > t_{\text{Cu}}$, so that the curves virtually coincide when $l_{\text{sf}}^{(\text{Cu})} > 20$ nm, as shown in Fig. 1. Next, the effects of the transverse ($l_{\text{sf}\perp}^{(\text{Co2})}$) (Fig. 2) and the longitudinal ($l_{\text{sf}\parallel}^{(\text{Co2})}$) (Fig. 3) spin diffusion length are analyzed at the free FM layer. It is found that $l_{\text{sf}\perp}^{(\text{Co2})}$ is a critical component in determining the magnitude of the STT in the free FM layer. As shown numerically in Fig. 2a, the maximum STT drops sharply by around 30% when increases from 1 nm to 2 nm. Subsequently, there is a further drop of 30% in the maximum STT magnitude with every 1 nm increment in $l_{\text{sf}\perp}^{(\text{Co2})}$. This suggests that $l_{\text{sf}\perp}^{(\text{Co2})}$ is a very sensitive parameter and a small fluctuation in its value could severely degrade the performance of the spin transfer switching. A decrease in $l_{\text{sf}\perp}^{(\text{Co2})}$ causes a stronger depolarization of the transverse spin accumulation (m_{\perp}), which results in an increased transfer efficiency of the transverse spin angular momentum to the local moments in the free FM layer, and thus induces an increase in STT. In addition, we also noticed that as $l_{\text{sf}\perp}^{(\text{Co2})}$ increases, the maximum STT is achieved at a larger θ . The total resistance change between the parallel and antiparallel configurations, i.e. $R(\pi) - R(0)$ is not affected by $l_{\text{sf}\perp}^{(\text{Co2})}$. However, the resistance $R(\theta)$ at an intermediate angle ($0 < \theta < \pi$) corresponding to non-collinear configuration, increases with increasing $l_{\text{sf}\perp}^{(\text{Co2})}$, as shown in Fig. 2b. Numerical analysis of the effects of longitudinal spin relaxation (i.e. variation of $l_{\text{sf}\parallel}^{(\text{Co2})}$) shows a significant degradation of both STT and $R(\theta)$ when $l_{\text{sf}\parallel}^{(\text{Co2})} < t_{\text{Co2}}$, as shown in Fig. 3. A high degree of spin relaxation, i.e. a short $l_{\text{sf}\parallel}^{(\text{Co2})}$ results in a stronger depolarization of the longitudinal spin accumulation (m_{\parallel}) in the free FM layer, and hence a reduction of $R(\theta)$ and the overall MR ratio (Fig. 3b). The high depolarization of the $l_{\text{sf}\parallel}^{(\text{Co2})}$ also causes an appreciable STT reduction, as shown in Fig. 3a.

Institució Catalana de Recerca i Estudis Avançats (ICREA) and Institut Català de Nanotecnologia, Bellaterra, Spain

Nitriding of austenitic stainless steel (ASS) at moderate temperatures ($\sim 400^\circ\text{C}$) leads to the formation of the supersaturated nitrogen solid solution often called in the literature “expanded austenite” or γ_N phase [1,2]. This causes an enhancement of the microhardness and the wear resistance without loss of the corrosion resistance. Moreover, this phase shows ferromagnetic behavior, whose origin is linked to the expansion of the austenite (γ) lattice due to the incorporation of nitrogen atoms into interstitial positions [3,4]. Nitrogen depth profiles consist of quasi-linear decrease from nitrogen near surface concentration of ~ 25 at.% to ~ 15 at.% followed by a sharp leading edge. The onset of ferromagnetism is connected with nitrogen concentrations of ~ 15 at.%, thus the nitrided layer consists of two magnetically different parts (paramagnetic and ferromagnetic) determined by the obtained nitrogen concentration.

In this study, we report the influence of the nitriding temperature and time on the ASS ferromagnetic properties. AISI 304L ASS polycrystalline samples (discs of 10 mm diameter and 2 mm thickness) have been ion beam nitrided in the temperature range of 300 – 400°C . The ion energy and the ion current density were ~ 1 keV and 0.5 mA/cm² (the corresponding ion flux of $\sim 510^{15}$ ions/cm²s⁻¹), respectively. The processing times were 5 and/or 30 minutes. Periodic arrays of ferromagnetic structures in the micrometer range have been prepared at the surface of the samples using a 2000 mesh Cu transmission electron microscopy grid as a shadow mask (mesh size of 7.5×7.5 μm^2 , 12.5 μm pitch, 20 μm thickness and 3.05 mm diameter). The structure was characterized by X-ray diffraction (XRD) and nuclear reaction analysis (NRA). The magnetic properties were determined by magneto-optical Kerr effect (MOKE) and magnetic force microscopy (MFM).

The XRD patterns of the nitrided ASS samples are presented in Figure 1. The XRD pattern consistent with the FCC lattice structure can be identified for the virgin ASS sample (not shown). For the nitrided samples, each austenite peak exhibits a satellite peak, located at lower diffraction angles which are related to the formation of the “expanded austenite”. The amount of this “expanded” phase increases with the processing temperature, as it is evidenced by the increase of intensity of the γ_N XRD peaks in detriment to the γ ones.

This is consistent with NRA observations. For instance, a nitrided layer of around 1 μm depth is obtained in the sample nitrided at 400°C for 30 min, whereas ~ 15 at.% of nitrogen is obtained around 0.5 μm of depth.

MOKE measurement results of the virgin and the nitrided sample at 400°C for 5 min are compared in Figures 2(a) and 2(b) (patterned area).

It can be seen that the virgin sample does not show any hysteretic behavior, i.e. it is non-ferromagnetic. Conversely, the nitrided samples show clear hysteresis loops indicating the existence of ferromagnetic constituents in the nitrided layer. Figure 2(c) shows the AFM image of a patterned area of the nitrided sample which shows that a moderate sputtering process of the surface has taken place during nitriding resulting in the formation of the periodic array of squared pits. Figure 2 (d) is the corresponding MFM image in an applied magnetic field of 70 mT, where a magnetic dipole-

lar contrast can be clearly seen in each entity, confirming the feasibility of the production of periodic arrays of isolated ferromagnetic structures. It is worth noting that the hysteresis behavior of the continuously nitrided areas and the patterned ones are quite similar due to the fact that the induced ferromagnetic structures are relatively large (micrometer range), leading to entities with magnetic multi-domain configurations.

Synthesis and characterization of particulate magneto polymer composite at microwave frequencies.

S. Borah, N. S. Bhattacharyya
Physics, Tezpur University, Tezpur, India

The present day technology trends towards compact, cost effective, light weight integration of microwave passive and active devices with transmission lines. Although heavy wave-guide components are indispensable when there is handling of high microwave power but medium and lower power handling devices are considered miniaturized hybrid microwave integrated circuits (MIC's) are taking over. To design MIC's the substrate, which is the guiding media, plays the important role. The selection of substrate depends on frequency of operation, the type of planar line used, desired electrical, mechanical and thermal properties and fabrication. Particle-filled polymer composites are taking forefront in the present day applications as the properties can be altered simply by varying quantity, distribution and microstructure of the reinforcing phase. Magnetic particles reinforced in polymer matrices have excellent potential for electromagnetic device applications at microwave frequencies as nonreciprocal devices, tunable cavities, electromagnetic interference [EMI] suppression etc. Essential characteristic of the magnetic substrate material which determines its utility at microwave frequencies is its permittivity and permeability. In addition it should have low magnetic and dielectric loss. Determination of complex permeability and complex dielectric properties of any substrate material is very important. Different techniques have been used for successful measurements of the dielectric properties of materials [1-3]. Cavity perturbation technique is the simplest technique which provides a bridge between theoretical calculation and experimental observation and it does not have a special requirement for the geometry and size of the measured sample [4].

In the present investigation, the dielectric properties of a new composite material are studied using the cavity perturbation technique. Cobalt-nickel ferrite with average crystallite diameters ranging from 5.76-17.55 nm are prepared with stoichiometric formula $\text{Co}_{1-x}\text{Ni}_x\text{Fe}_2\text{O}_4$ ($x = 0, 0.2, 0.4, 0.6, 0.8, 1.0$) using conventional chemical route. The substrate material is fabricated by reinforcing the ferrite in different volume fraction into low density polyethylene (LDPE) matrix [5,6]. Transmission Electron Microscopy (TEM), Scanning Electron Microscopy (SEM) and X-ray diffraction (XRD) patterns indicate the uniform particle indicate the uniform particle size, distribution and cubic spinel structure ferrite samples. The B-H loop study conducted at 10 kHz on the toroid shaped composite samples shows reduction in magnetic losses as compared to bulk sample.

The measurement of the dielectric constant of the sample is carried out in a TE₁₀₃ mode rectangular waveguide cavity at 9.68 GHz with $Q = 3226$. The sample is placed at a point of maximum electric field. Permittivity of $\text{Co}_{1-x}\text{Ni}_x\text{Fe}_2\text{O}_4$ – LDPE composite materials are found to be very high and the dielectric losses are found to be small as compared to the conventional bulk ferrites used for microwave passive devices Enhancement of permittivity value is observed with increase in % volume fraction of the reinforcer in the composite. The results are verified using Bruggeman's Theory [7].

Nanocrystals formation in $\text{Ce}_{100-x}\text{Al}_x$ ($x=45, 50$) ribbons by rapid solidification from the liquid state.

B. Idzikowski¹, Z. Sniadecki¹, D. Kaczorowski²

1. Institute of Molecular Physics, Polish Academy of Sciences, Poznan, Poland; 2. Institute of Low Temperature and Structure Research, Polish Academy of Sciences, Wroclaw, Poland

The heavy-fermion (HF) behavior is observed not only in a selected crystalline compounds but also in amorphous or nanocrystalline metallic matter. In conventional systems the strength of the exchange interaction between localized f -electrons and conduction electrons can be completely turned up by a specific stoichiometry, which create internal pressure (or also by external pressure), resulting in domination of either Kondo-type or the RKKY interactions. This is a consequence of the competition between the magnetic order and local Kondo resonance. HF behavior could be strongly enhanced by topological disorder, lattice defects or nanocrystalline structure. It is known that such kind of disorder cause substantial modifications of the low temperature properties of a HF materials resulting in a breakdown of the Fermi-liquid behavior. The interplay between structural disorder and strong correlations of electrons can be studied as a function of number and size of nanocrystalline grains embedded in an amorphous matrix.

Cerium shows variable electronic structure and dual valency states, because only low energy is sufficient to change the relative occupancy of its electronic levels. The interaction of RKKY-type decreases when the average distances between Ce atoms increases, e.g. by substitution of Ce by Al atoms in $\text{Ce}_{100-x}\text{Al}_x$ system. Usually amorphous HF alloys exhibit non-Fermi-liquid behavior at low temperatures. Topological disorder in these alloys is not so considerable as in mixed amorphous/nanocrystalline systems but due to the random substitution of constituent elements creation of the Kondo and/or Anderson lattices were observed.

In this paper the nanocrystalline state formation, crystallization processes, crystal structure of nanoparticles in $\text{Ce}_{100-x}\text{Al}_x$ are investigated. The master alloys with $x=45, 50$ were prepared by arc-melting of the Al and Ce elements with at least 99.9% purity under argon atmosphere on a water-cooled copper boat. Then the master alloys were rapidly quenched using a single roller melt-spinner with a Cu wheel. Cooling rates during melt spinning were controlled by the wheel surface velocity ($v=40$ m/s) or hole diameter in the quartz crucible. The ribbons are about 2 mm in width and 20-40 μm thick. For structural characterization x-ray diffraction (XRD) was used. Measurements were made on a diffractometer with $\text{Co K}\alpha$ radiation in Bragg-Brentano geometry. The crystallization behavior of as-quenched samples was investigated by DSC measurements using Netzsch DSC404 apparatus between room temperature and 900°C with 20 K/min heating rate.

The XRD patterns for both compositions (Fig. 1) show Al_iCe_j nanocrystalline phase with the ClC_2 -type structure (Pm-3m space group) embedded in an amorphous matrix. This crystalline Al_iCe_j phase is known from A.A. Yakunin *et al.* [1] paper as a metastable one, without determined distribution of Ce and Al atoms in the lattice cell. The $\text{Ce}_{100-x}\text{Al}_x$ ($x=45, 50$) ribbons due to differences in Ce/Al ratio are in different nanocrystalline states, what suggests that amount of nanocrystals could be roughly controlled during rapid quenching process. The constant-heating DSC curves (Fig. 2) for $\text{Ce}_{50}\text{Al}_{50}$ and $\text{Ce}_{55}\text{Al}_{45}$ show two exothermal crystallization peaks at temperatures T_{x1} and T_{x2} with crystallization onset temperatures at $T_{\text{onset}1}$ and $T_{\text{onset}2}$, respectively. For $\text{Ce}_{55}\text{Al}_{45}$ one can see third small event at about 350°C , which is not visible for $\text{Ce}_{50}\text{Al}_{50}$ at this heating rate. Summary enthalpy ΔH of first two peaks is about 20 J/g for both alloys. Endothermic effects associated with a glass transition below the primary crystallization peak T_{x1} are not visible against the other effects. This could indicate the presence of dispersed polyamorphous packings [2] with a wide

range of local glass transitions, secondly the glass transition T_g is close or above T_{x1} , or finally $\text{Ce}_{100-x}\text{Al}_x$ ($x=45, 50$) system would be similar to Al-based metallic glasses where T_g is not visible in standard constant-heating DSC scans (as shown in our previous paper about Al containing pseudo-ternary rare earth – transition metal – metal/metalloid alloys [3]).

Noise enhanced stability of magnetic systems.

M. Trapanese

Dipartimento di Ingegneria Elettrica, Elettronica e delle Telecomunicazioni, University of Palermo, Palermo, Italy

Escape from a metastable state is a phenomenon observed in several scientific areas. Among them there are the theory of diffusion in solids, chemical kinetics, and transport in complex systems.

The decay of magnetization with time (the aftereffect) can be interpreted as an escape from a metastable towards states closer and closer to the ground state and therefore studied with the theoretical means developed for diffusion processes. The rate of the decay of magnetization can be affected from applied fields and temperature. Even though at zero field and room temperature, aftereffect is unmeasurable, under particular conditions it becomes measurable leading to decay rates that can be seriously affect the working condition of a permanent magnet (i.e. the life span of a permanent magnet in electric machine can be seriously affected from temperature or a magnetic memory could shorten its life because of the presence of a reverse field). As a result, the study of the stabilization of magnetization could have a serious technological impact.

The study of mean first passage time (MFPT) is one of the parameters often considered in the theory of diffusive process. The mean first passage time of a Brownian particle moving in potential fields usually decreases with noise intensity according to the Kramers formula or some universal scaling function of the system parameters. The dependence on the noise intensity of the MFPT for metastable and unstable systems was revealed to have resonance character by Hirsch et al. [1] and then observed in different physical systems [2-7]. The most important conclusion of these studies is that the noise can modify the stability of the system in a counterintuitive way. The system remains in the metastable state for a longer time than in the deterministic case and the escape time has a maximum at some noise intensity. Noise-enhanced stability (NES) was originally found numerically by Dayan et al. [2], and observed experimentally in a tunnel diode by Mantegna and Spagnolo [4]. More recently, it was found that the noise induced slowing down [7] and the noise-induced stabilization are related to NES phenomenon.

NES in magnetic systems has not yet been fully investigated.

The main purpose of this paper is to study NES in magnetic systems. The magnetization of magnetic materials in zero field decays very slowly toward its ground state. This is due to the effect of large energy barriers. However, under the presence of a reverse field this effect can be accelerated. This field is named holding field.

In this paper NES in magnetic systems is studied by Preisach-Arrhenius (PA) like model (8) and by dynamic simulation. In PA model a controllable fluctuating field is added to the usual thermal fluctuating field of PA model. In the dynamic simulation an external magnetic field (h_{ext}) applied to a magnetic material consisted of two components: one small asymmetrical periodical component added to a gaussian noise component. The value of h was computed at several time steps. As a result the history of the magnetization of the system could be computed by using Preisach Model. As a result the magnetization followed a history that resulted by the composition of a asymmetrical component and a gaussian component. The time needed to jump from the unstable part of the magnetization to the stable part was recorded as a function of the applied noise.

NES is studied for three systems: a toy model of a magnetic materials, a systems made from non-interacting hysteron and a Gaussian material.

First, a toy model of a magnetic material is considered. This toy model consists of very few hysteron. The decay rate of this model is studied as a function of the controllable fluctuating field. It is shown that NES occurs for this system.

In the non interacting hysteron material hysteron are supposed to be placed in the Preisach plane along the line $u=-v$. The decay rate can be computed and it is shown that it has a non monotonic behaviour as a function of the controllable fluctuating field. As a result NES occurs also in this case. The dynamic simulation confirmed the presence of NES by showing a non monotonic behaviour of the decay rate of magnetization from the unstable state to the stable state.

Finally, a Gaussian material is considered. In this case, the after effect and the effect of the controllable fluctuating field can be computed by integrating on the whole Preisach plane. The aftereffect has been computed for several holding field as a function of the controllable fluctuating field. Also in this case a non monotonic behaviour of the decay rate as a function of the controllable fluctuating field is detected. This is the signature of NES. The dynamic simulation confirmed the presence of NES by showing a non monotonic behaviour of the decay rate of magnetization from the unstable state to the stable state.

Implementing mixture design to predict magnetic properties of hybrid bonded magnets.

J. Hsu¹, P. Sharma¹, A. Verma²

1. Physics, National Taiwan University, Taipei, Taiwan; 2. Moserbaer India Ltd, Greater Noida, India

Introduction

Hybrid bonded magnets exhibit variation in magnetic properties depending upon the blend i.e. weight fractions of magnetic powders, binder and the processing condition [1]. It is interesting to know the magnetic properties of each blend in order to tailor-made required magnetic energy. This study can be carried out by mixing the constituents in several proportions and measuring the magnetic properties. The major drawback of the said-approach is running a large number of experiments. On the other hand, the approach taken in the present study is to conduct only a few experiments and use the information to develop a mathematical model valid in the studied range of composition. In this study, a three-component constraint mixture design was implemented [2]. The focus was to fit the mathematical equations to model the response and to predict the magnetic property to any mixture over the studied composition range. In the present investigation, the compression moulded hybrid bonded magnets of strontium ferrite (SrFe₁₂O₁₉) and neodymium iron boron (NdFeB) rapidly solidified isotropic flakes with 10 different composition were made. Some design points are also replicated. The epoxy resin was used as a binder. The constraints applied on weight fraction of each component were: $0.25 \leq W_{\text{Ferrite}} \leq 0.72$; $0.25 \leq W_{\text{NdFeB}} \leq 0.72$; $0.03 \leq W_{\text{Binder}} \leq 0.07$, where W_{Ferrite} , W_{NdFeB} and W_{Binder} are the weight fraction of SrFe₁₂O₁₉, NdFeB and binder respectively.

Results and discussion

The magnetic properties such as remanence (B_r), coercivity (H_c), and energy product (BH)_{max} of bonded magnets were measured. Using measured properties various regression model were fitted. Computer aided design D-optimal was used to fit the regression models [2, 3]. Full cubic model was found to be the most suitable model for each magnetic properties. The R square value is more than 95% which suggests that regression equations are adequate to fit the measured data. The produced equations for (B_r), (H_c) and (BH)_{max} are given in Eqs. (1), (2) and (3) respectively.

$$(B_r) = -2371.88W_{\text{Ferrite}} + 869.89W_{\text{NdFeB}} + 9.50\exp(+6)W_{\text{Binder}} + 172.90W_{\text{Ferrite}}W_{\text{NdFeB}} - 1.50\exp(+7)W_{\text{Ferrite}}W_{\text{Binder}} - 1.50\exp(+7)W_{\text{NdFeB}}W_{\text{Binder}} + 1.11\exp(+7)W_{\text{Ferrite}}W_{\text{NdFeB}}W_{\text{Binder}} + 6834.69W_{\text{Ferrite}}W_{\text{NdFeB}}(W_{\text{Ferrite}} - W_{\text{NdFeB}}) + 5.54\exp(+6)W_{\text{Ferrite}}W_{\text{Binder}}(W_{\text{Ferrite}} - W_{\text{Binder}}) + 5.56\exp(+6)W_{\text{NdFeB}}W_{\text{Binder}}(W_{\text{NdFeB}} - W_{\text{Ferrite}}) \quad (1)$$

$$(H_c) = -8042.43W_{\text{Ferrite}} - 2346.74W_{\text{NdFeB}} + 4.33\exp(+7)W_{\text{Binder}} + 1497.14W_{\text{Ferrite}}W_{\text{NdFeB}} - 6.83\exp(+7)W_{\text{Ferrite}}W_{\text{Binder}} - 6.83\exp(+7)W_{\text{NdFeB}}W_{\text{Binder}} + 5.06\exp(+7)W_{\text{Ferrite}}W_{\text{NdFeB}}W_{\text{Binder}} + 13620.12W_{\text{Ferrite}}W_{\text{NdFeB}}(W_{\text{Ferrite}} - W_{\text{NdFeB}}) + 2.53\exp(+7)W_{\text{Ferrite}}W_{\text{Binder}}(W_{\text{Ferrite}} - W_{\text{Binder}}) + 2.53\exp(+7)W_{\text{NdFeB}}W_{\text{Binder}}(W_{\text{NdFeB}} - W_{\text{Binder}}) \quad (2)$$

$$(BH)_{\text{max}} = -2.96W_{\text{Ferrite}} + 0.49W_{\text{NdFeB}} + 13704.07W_{\text{Binder}} - 7.07\exp(-3)W_{\text{Ferrite}}W_{\text{NdFeB}} - 215.84W_{\text{Ferrite}}W_{\text{Binder}} - 215.92W_{\text{NdFeB}}W_{\text{Binder}} + 1.60W_{\text{Ferrite}}W_{\text{NdFeB}}W_{\text{Binder}} + 6.95\exp(-4)W_{\text{Ferrite}}W_{\text{NdFeB}}(W_{\text{Ferrite}} - W_{\text{NdFeB}}) + 0.80W_{\text{Ferrite}}W_{\text{Binder}}(W_{\text{Ferrite}} - W_{\text{Binder}}) + 0.807W_{\text{NdFeB}}W_{\text{Binder}}(W_{\text{NdFeB}} - W_{\text{Binder}}) \quad (3)$$

These regression equations can be directly used to predict the magnetic properties for any weight fraction of ferrite, NdFeB and binder. However, the sum of weight fractions of all component should be unity.

To check the adequacy of the fitted model equations, some experiments at specific design points were repeated in the same experimental condition and their magnetic properties were measured.

Further the measured magnetic properties were compared with the predicted properties from the model equation. The deviation of actual magnetic properties of the bonded magnets from predicted one using mathematical model was shown in Fig. 1. It depicts that predicted magnetic properties are in agreement with the actual one. The difference in the magnetic properties is in acceptable limits.

Conclusion

The studies on the hybrid-bonded magnets of SrFe₁₂O₁₉ with NdFeB show that the constraint mixture design is adequate to predict the role of each component on the magnetic properties. In the present full study cubic model was found to be suitable for predicting (B_r), (H_c), (BH)_{max}. The present approach proposes a new methodology to develop mathematical equations for predicting properties of bonded-magnets and could be successfully implemented to the industry to design the properties of specific interest.

Establishment of multipole magnetizing method and apparatus using a heating system for Nd-Fe-B isotropic bonded magnets.

H. Komura, M. Kitaoka, T. Kiyomiya, Y. Matsuo
R & D, FDK Corporation, Kosai, Japan

[Introduction]

We examined multipole magnetizing method for Nd-Fe-B isotropic bonded magnets that contributes to the miniaturization of electromagnetic devices, and developed a new method using heating system. As it showed very strong magnetization characteristics, we called this method Ultra High Magnetizing (UHM) process. [1] The next problem is to contrive the way of adjusting magnetization characteristics. It is very important to apply this method to various industrial applications. Then, we did various examinations, and finally we devised it by using thermal demagnetization characteristics of magnets, and established the way of an adjustment of magnetization characteristics. In addition, we found the stability of magnetization characteristics with the thermal history than that of conventional technology. By these examinations, we were able to establish a magnetizing method and its apparatus.

[Experimental Procedure]

This method involves cooling the specimens in the magnetizing field using permanent magnets after rapid heating to temperatures above the Curie point of the Nd-Fe-B magnets. Furthermore, we installed a heater in the magnetizing field and enabled an adjustment of the temperature. We used three kinds of magnet powder and made ring-type bonded magnets with outside diameter= ϕ 2.6 mm, inside diameter= ϕ 1.0 mm, and length=3 mm. Figure 1 shows demagnetization curves of bonded magnets. Magnetization to 10 poles from outer of the bonded magnet was given. The temperature of the magnetizing field changed variously, and magnetization characteristics were evaluated. In addition, it is thought that initial demagnetization behavior of the UHM process is different from that of conventional technology because the heating history is given during magnetization. Therefore we compared the thermal flux loss with conventional technology.

[Results and Discussion]

Figure 2-a. shows the UHM magnetization characteristics with an adjustment of the temperature, and figure 2-b. shows the ratio of demagnetization on the basis of magnetization characteristics at 50 degrees centigrade in each magnet. The magnet with high coercivity shows higher magnetization characteristics and lower ratio of demagnetization. Figure 3 shows the thermal flux loss of the UHM process compared with conventional technology. The thermal flux loss of the UHM process, especially the magnet with lower coercivity, is smaller than that of conventional technology. It is thought that obtained magnetization characteristics contain initial demagnetization in the UHM process because the UHM process is including heating process. By the above, it became clear that an adjustment of magnetization characteristics is possible by an adjustment of the temperature in the magnetizing field of the UHM process. However, because the range that can be adjusted depends on the magnetic characteristics, it is necessary to select the magnet powder appropriately. As other advantages, it was clarified that the UHM process is excellent in the stability of magnetization characteristics with the thermal history compared with conventional technology.

Investigation of eddy current loss in divided Nd-Fe-B sintered magnets for synchronous motors due to insulation resistance and frequency.

K. Yamazaki¹, M. Shina¹, M. Miwa², J. Hagiwara²

1. Dept. of Electrical, Electronics and Computer Engineering, Chiba Institute of Technology, Narashino, Japan; 2. TDK Corporation, Ichikawa, Japan

Owing to the progress of Nd-Fe-B magnets, permanent magnet synchronous motors are widely applied to the industry as highly efficient motors. On the other hand, as the resistivity of the magnet is relatively low, considerable eddy current loss is generated by the harmonic magnetic fields in the motor. It may cause the thermal demagnetization of the magnets. Accordingly, the magnets are often divided into several pieces to prevent the eddy currents.

There are several reports that investigated the eddy current loss in the divided magnets. Reference [1] reported the eddy current loss calculation of the permanent magnet in the synchronous motor. However, it did not compare the measured and calculated magnet eddy current loss, because the separation of the loss from the other losses in the motor is impossible in the measurement. Reference [2] investigated the effects of the magnet division by the simple experiment with the magnet specimen and an exciting coil. However, in the synchronous motor, the loss is generated by various kinds of harmonic magnetic fields. In addition, the critical insulation resistance between the divided magnets to obtain the loss reduction effect is also unclear.

In this paper, we investigate the loss reduction effect of the divided magnets from both results of the simple experimental apparatus and the synchronous motor, in order to clarify the effects due to the insulation resistance, frequency, and number of magnet divisions. First, the measured results of the simple experiment are compared with the 3-D finite element analysis to verify the validity. Next, the analysis of a permanent magnet synchronous motor is carried out.

Fig.1 shows the basic experimental apparatus to measure the eddy current loss of the divided magnets. The Nd-Fe-B magnets with thermal sensor are placed at the center of an exciting coil. The remanent flux density is 1.26T and resistivity is $1.3 \times 10^{-6} \Omega\text{m}$. After surrounding the magnet by the heat insulation material, the coil is excited by AC current whose frequency is 1 to 30kHz. The eddy current loss is estimated from the increase of the temperature during 5 minutes.

Fig.2 shows the experimental and calculated eddy current losses due to the insulation resistance, when the frequency is 1kHz and the magnet is divided into 4-pieces as shown in Fig.1. The resistance is varied due to the surface treatment of the magnet. Although the calculated results underestimate the loss, the tendencies are agree well. Both results show that the loss much increases when the insulation resistance is less than $0.01 \Omega\text{m}$. On the other hand, it is almost constant over this region. The critical insulation resistance is clarified. Fig.3 shows the experimental and calculated loss due to the number of magnet divisions and frequency. It indicates that the loss reduction effect by the magnet division is weakened when the frequency is high.

The 3-D finite element analysis of the interior permanent magnet synchronous motor is carried out as shown in Fig. 4. The permanent magnet is affected by the various kinds of harmonic magnetic fields whose frequencies are kHz order. The loss reduction effect by the divided magnets shows same tendency as the basic experiment. It is also weakened, especially in the case of the high order harmonic fields.

I. INTRODUCTION

Magnetically suspended drives attract attentions by flywheel, pump and compressor drives. A bearingless motor combines functions of both non-contact magnetic suspension and torque generation together in a single motor. Therefore, the characteristics of magnetic bearing, no wear particles, less maintenance, and higher rotational speed are realized. In addition, a bearingless motor possesses the great advantages of downsizing, a simple structure and cost reduction, in comparison with a conventional tandem structure composed of magnetic bearings and a motor. Compact magnetically suspended bearingless motors are applicable for flywheel satellite posture regulation and home appliance energy storage system, and etc.[1]

The authors have proposed and fabricated a two-axis controlled noncontact bearingless drive system with passive magnetic bearings. This prototype machine is constructed by two-axis active position regulation having one unit of a bearingless motor with a consequent-pole permanent magnet (PM) rotor. The suspension and rotation tests were performed [2~3]. The rotor can be suspended, when it displaces within 0.1mm in radial direction. But touch down displacement of 0.3mm is requested in the point of view of mechanical process precision. The prototype machine was not able to start up at displacement of 0.3mm.

In this paper, an improved structure of a new prototype machine is proposed. The new structure is designed using three-dimensional Finite Element Method (3D-FEM). It is shown that start up is achieved from the touch down displacement of 0.3mm in experiment.

II. STRUCTURE OF BEARINGLESS MOTOR AND PASSIVE MAGNETIC BEARINGS

Fig.1 shows the x-z cross section of the proposed bearingless motor drive. A rotating part is in ring shape surrounding the stator part. In the stator part, a shaft is fixed to a base. Around the shaft, a stator core and windings are constructed. In the rotor part, there are three PM layers. The center PMs are radially magnetized, and are used for the bearingless motor functions generating torque and radial active forces. The PMs in the left and right are for axial-conical passive magnetic bearings. With the passive magnetic bearings, stiffness is enhanced in the three-axis movements, i.e., axial and conical directions. But unbalanced magnetic pull force is caused by PMs in the passive magnetic bearings. Then, negative stiffness is resulted in the two radial x- and y-axes. The magnetic pull force is mostly proportional to the rotor radial displacement. Thus, magnetic pull force is high at large displacement. Thus, a prototype bearingless motor was not able to start up at 0.3mm displacement.

To start up at 0.3mm displacement, high active suspension force of bearingless motor is needed. A design of rotor iron and PM structure is improved to enhance suspension force capability for start up using 3D-FEM. The detail of improved design will be included in presentation and 4-page paper.

III. EXPERIMENTAL RESULT

Fig.2 shows the displacement waveforms at start-up in developed prototype bearingless motor based on the proposed design. Before the suspension system is active, the x-axis rotor displacement is 0.3mm, and y-axis rotor displacement is 0.08mm. Thus, a rotor is touched down in x-axis. When the suspension system is activated, the displacements of x-axis and y-axis are moved to the center

position. It is seen that successful magnetic suspension is achieved. The start-up is achieved from the touch down displacement of 0.3mm.

IV. CONCLUSION

In this paper, the design of an outer rotor consequent-pole type bearingless motor with passive magnetic was shown. The proposed motor design provides a start-up capability at displacement up to 0.3mm. In the experiment, it was shown that the proposed prototype machine is able to start up at 0.3mm displacement.

Study of the Static Force by the Difference in the Winding Structure of Permanent Magnet Type Linear Synchronous Motor.

K. Suzuki¹, Y. Kim², H. Dohmeki¹

1. Department of Electrical and Electronic Engineering, Musashi Institute of Technology, Tokyo, Japan; 2. Department of Electrical Engineering, College of Engineering Chosun University, Gwangju, South Korea

I. INTRODUCTION

Recently, permanent magnet linear synchronous motor (PM-LSM) is used as a driving source in transportation systems. Usually, an initial cost of PM-LSM rises to employ a full-length armature-side-on-ground design. Thus our laboratory have proposed a discontinuous armature type PM-LSM (DPM-LSM) [1]. Fig. 1 shows the arrangement of proposed system. However, the armature has an outlet edge on structure [2]. From Fig. 1, a secondary mover advances into an armature gradually from free running. A generated thrust changes with numbers of magnetic poles of the secondary mover which overlaps the armature. Thus the armature structure of generated thrust sufficient also with a few magnetic poles is required. This paper compares the static force of each winding structure. The static force to measure is the thrust generated at the time of the secondary mover advancing into the armature. It is made comparison with the ratio of the static force produced from the magnetomotive force of the armature by winding structure. From this ratio, the winding structure of LSM used for discontinuous arrangement is determined.

II. WINDING STRUCTURE OF DPM-LSM

The structure of LSM compares two kinds. It is the distributed winding from which winding is distributed over two or more slots. Another structure is concentrated winding which winding concentrates on one slot. This distributed winding is short pitch winding in which the coil pitch of the armature is shorter than the secondary mover's pole pitch. The numbers of poles of an armature are 9 poles. And, the magnetic poles of a secondary mover are 8 poles. Next, the numbers of slots of the armature of this concentrated winding are 9 slots, and the numbers of magnetic poles of the secondary mover are 28 poles. The magnet which overlaps with the armature completely becomes 12 poles. Therefore, the magnetic pole and the slot are 4 poles 3 slots.

III. MEASUREMENT AND EXAMINATION OF STATIC FORCE

Measurement of the static force of each current and the cogging force in each winding structure uses a Push-Pull load cell, and pushes and measures the secondary mover by the draw gear. The position-static force characteristics of LSM are shown in Fig. 2. From Fig. 2, the static force is increasing because the secondary mover advances into the armature gradually. In the outlet edge, the magnetic pole which overlaps with the winding of the armature changes with a secondary mover's positions. Therefore, the armature which gives generated thrust sufficient also in the state with few magnetic poles is required. The thrust constant is computed from the static force when the magnetic pole of the secondary mover overlaps with the armature of LSM completely.

Table I shows each calculated parameter. Since each LSM differs in the size of equipment, or the permanent magnet and the number of winding, comparison is difficult for it. Therefore, the ratio of the magnetomotive force F at the time of the rated current produced per winding to the maximum thrust force F_{max} compares. From Table I, it can be found with $F/F_{max}=2.082$ A/N of the distributed winding LSM. Similarly, it can be found with $F/F_{max}=4.514$ A/N of the concentrated winding LSM. The concentrated winding of the thrust produced per magnetomotive force of winding is larger.

IV. CONCLUSION

In this paper, each static force of the distributed winding LSM and the concentrated winding LSM was measured, and the ratio of the maximum thrust in the magnetomotive force of winding was computed. The result has checked that the thrust had occurred effectively from the structure of the winding to field system magnetic flux in the direction of the concentrated winding LSM. Therefore, an effective winding structure of LSM where the outlet edge exists is concentrated winding.

Proposal of the Air-core Type Linear Synchronous Motor Using the Air Levitation System.

K. Suzuki¹, Y. Kim², H. Dohmeki¹

1. Department of Electrical and Electronic Engineering, Musashi Institute of Technology, Tokyo, Japan; 2. Department of Electrical Engineering, College of Engineering Chosun University, Gwanju, South Korea

I. INTRODUCTION

The linear motor (LM) of direct drive has been produced and distributed mainly through factory automation (FA) transportation field focusing on high speed, low noise, simplification of driving apparatus and simplification of maintenance [1]. However, LM needs to contact and support a secondary mover. These linear motors cannot be used in a clean room by contamination of dust. Then, the mechanism which supports the secondary mover by non-contact is required for LM. We propose an air levitation system. This paper examines an air levitation type permanent magnet type linear synchronous motor (ALPM-LSM) which used porosity aluminum for the used support mechanism. Friction of this system is zero at the time of levitation. This motor can run by a low thrust. Then, the design of small PM-LSM of a low thrust which uses a air-core coil is described.

II. THE STRUCTURE OF ALPM-LSM

The air levitation system of this research uses porous aluminum material for the used support mechanism. Fig. 1 shows ALPM-LSM. From Fig. 1(b), air is sent to the cavity of a used machine style, and a secondary mover always levitates with the air which leaked from porosity aluminum. The secondary mover of ALPM-LSM levitates 98 μ m with air, and runs.

III. THE DESIHN OF ALPM-LSM

Friction of ALPM-LSM is zero at the time of levitation. Moreover, it is necessary to carry out the weight saving of the secondary mover's weight. This motor can be designed small by a low thrust force. The demand thrust is set to $F^*=0.447$ N, when it is made into secondary mover's weight $M=0.447$ kg and acceleration $a^*=1$ m/s². Next, the thrust force of LSM is generated according to the flux density B_g [T] in the air gap and the magnetomotive force of the coil of the armature. Thus the thrust force needs to calculate the flux density in the air gap. The flux density in the air gap is computed from the magnetic circuit in an air gap [2]. The concept of the magnetic circuit in the air gap is shown in Fig. 2. From Fig. 2, each magnetic reluctance R_{ml} , R_g , and R_{air} in an air gap are computed. A magnetic circuit consists of magnetomotive force of the computed magnetic reluctance and a permanent magnet. The flux density in the air gap was computed with $B_g=0.198$ T.

IV. MAGNETIC FIELD ANALYSIS BY FINITE ELEMENT METHOD

Magnetic field analysis of ASPM-LSM is conducted using the two-dimensional finite element method. Analysis asks for the static flux distribution in the air using the model of the secondary mover. Fig.3 shows the analysis result of the flux density of the finite element method. The value of the flux density of Fig. 3 is 4mm from the surface of a permanent magnet. This result is taking the thickness of the air gap and the coil into consideration. From Fig. 3, the analysis result of flux density is maximum $B_{max}=0.187$ T. Compared with flux density $B_g=0.198$ T in the gap for which it asked from the magnetic circuit, the deflection as a result of magnetic field analysis is 5.65%. For the reason, the flux density for which it asks from the magnetic circuit is appropriate.

V. MEASUREMENT OF AN INDUCED VOLTAGE BY AN EXPERIMENTAL DEVICE

Induced voltage e [V] of an experimental device is measured and the flux density in the air gap is computed. As a result, the flux density was computed with $B_g'=0.114$ [T]. Compared with the flux density of a magnetic circuit and the finite element method, the deflection of flux density B_g' is

42.6%. This became small by the leakage flux which is not taken into consideration with the magnetic field circuit and the two-dimensional limited element.

VI. CONCLUSION

This paper described the design of the air levitation type PM-LSM. The design of LSM which uses the air core coil needs to constitute the magnetic circuit from three dimensions, and needs to compute the flux density in the air-gap.

I. INTRODUCTION

Nowaday, linear oscillatory actuator (LOA) are widely use in various application. It gives a rapid linear motion either in term of forward or backward direction. However, both directions or oscillatory motion can be achieved when AC power is supply to the LOA [1]. The purpose of the LOA development in this research is to work as a pruner. The LOA has been designed using FEM in [2] and mention as model A. However, the thrust produce is inadequate and need to improve. In this paper, the permeance analysis method (PAM) is use to optimize the thrust of LOA. The main constrain this research is to maintaining it weight below 2kg and size below 30mm diameter and 120mm length.

The PAM use magnetic equivalent circuit (MEC) approach that consists in building of a permeance network. By using PAM, it is necessary to assume magnetic path as a whole, and the analytical results are influenced by the assumption of air gap magnetic flux distribution [3]. The PAM technique also made effect of dimension of LOA structure to the thrust can be evaluate [4].

The optimization is done by varies the size of permanent magnet, r_m and coil, H_c . To avoid magnetic saturation effect, high of slop, r_2 and length between coils, l_{cc} need to adjust at same value of r_m and H_c . As a result, the high thrust of LOA has been designed with 450N of maximum thrust, the LOA weight is 2.0kg and overall size of LOA is 30mm diameter and 115mm length.

II. MAGNETIC EQUIVALENT CIRCUIT OF LOA

A. Structure of LOA

The structure and parameters of LOA is shows in fig. 1. These parameters will be use to develop the permeance equations in order to calculate the thrust of LOA.

B. Permeance and Magnetic Equivalent Circuit of LOA

The MEC was developed base on the permeance model of LOA. The permeance model is built depending on the estimated magnetic flux path at the air gap with following assumptions.

- 1)The permeability of the yoke is regarded as infinity.
- 2)The leakage flux is disregarded.

The permeance model and MEC of LOA are shows in fig 2. The permeance values are calculated using basic equation as equation (1).

$$P = (\mu_0 a) / l \quad [\text{H/m}] \quad (1)$$

Where P is the permeance value in (H/m), μ_0 is the air permeability in (N/A²), a is the air gap area in (m²) and l is the air gap length in (m).

Magnetic energy and thrust value are expressed as equation (2) and (3).

$$W_m = NI(\Phi_{PM} + \Phi_C) \quad [\text{J}]$$

$$W_m = NI(B_k \Phi_m + NIPT) \quad [\text{J}] \quad (2)$$

$$F = \delta W_m / \delta x \quad [\text{N}] \quad (3)$$

Where W_m is a magnetic energy in (J), Φ_{PM} is a permanent magnet magnetic flux in (Wb), Φ_C is a coil magnetic flux in (Wb), NI is a coil magneto motive force in (A), B_k is a magnetic flux den-

sity at operating point of permanent magnet in (T), Φ_m is a cross area of permanent magnet in (m²) and PT is a permeance total for every magnetic equivalent circuit in (H/m).

III. THRUST CALCULATION

The thrust characteristic using PAM for this LOA has been calculated. The value of thrust calculated using PAM also has been compare to FEM and measured result using model A at same value of input power. As a result, difference about 15% of maximum thrust between these three methods. The optimized thrust with optimized parameter of LOA structure has been calculated. As a result, the LOA has been designed with having high value of thrust and optimum parameter. The thrust value is also compared to the FEM result. The comparison between the results is as shows in fig. 3.

IV. CONCLUSIONS

The thrust value of LOA has been calculated using PAM and compared with FEM and measured value. As a result, the LOA which is having high value of thrust has been designed. Increasing about 350N on the LOA thrust has been obtained by the optimized model compared to model A.

Optimal design of barrier shape improve torque of interior permanent magnet synchronous motor.

C. Jin, J. Lee

Hanyang University, Seoul, South Korea

The steady-state performance analysis and accuracy control of Interior Permanent Magnet Synchronous Motor (IPMSM) extremely depends on accurate determination of its parameters. The three important parameters of the IPMSM are magnet flux linkage, d-axis and q-axis inductances. Torque of IPMSM is divided into two parts. One is alignment torque and the other is reluctance torque.

Alignment torque depends on permanent magnet flux linkage, and reluctance torque relies on d-axis and q-axis inductance. Torque equation of IPMSM is shown (1).

$$T = P(\Psi I_q + (L_d - L_q) I_d I_q) \quad (1)$$

One of the important factors of flux linkage, d-axis and q axis inductance is design shape of barrier. What is more, Shape of barrier is affected of length of rib.

This paper deals with proposal that optimal of barrier shape considering length of rib and q-axis inductance to improve torque IPMSM.

Design details for the IPMSM designed to operate constant torque 20Nm in the 45rpm(speed) / 12V(EMF) of constraint and to deliver 800W constant power over a 3:1 speed range extending from 400rpm to 1300rpm for washing machine. And this model has 8pole and 12slot. Fig 1 shows the model of IPMSM.

After design of the IPMSM for washing machine, the IPMSM test sample is manufactured on the basis of though verification of result of FEM. It progress to measure characteristic of test sample.

The agreement between amplitude of the predicted and measured of back-EMF is so good, but there is a serious difference between the amplitudes of the predicted and measured of torque. The amplitude of the measured torque is 17Nm while predicted torque is 20Nm.

Outcome of investigation about this problem, short length of rib cause rotor of IPMSM to increase reluctance torque with increasing q-axis inductance and current phase angle, to drop characteristic of magnetic torque. It is significant that magnetic torque is more effective than reluctance torque in constant torque region. Cause of magnetic torque drop is a part of magnetic flux linkage leak out through barrier and rib. And cause of reluctance torque's influence is extended increase of q-axis inductance and current phase angle.

But maybe it is not considered FEM analysis about above alluded to problem.

If that is the case, length of rib can not increase lack of definite view in mind. Because reluctance torque decrease under the influence decrease of q-axis inductance by saturation effect.

Consequently, it must design details of barrier shape considering length of rib and d- and q-axis inductance.

Fig 2 and Fig 3 show torque versus the angle of the current phase and torque versus current respectively.

It is verified improve the torque of IPMSM through manufacture of optimizing test sample.

Torque versus the current

Feasibility Study of a Passive Magnetic Bearing Using the Ring Shaped Permanent Magnets.

T. Azukizawa, S. Yamamoto, N. Matsuo
Kobe University, Kobe, Japan

1. Introduction

Magnetic bearings have the distinct features such as clean, noiseless, vibration free and maintenance free. However, high cost due to control apparatus for 5 degrees of freedom of the rotor, prevent their wide applications at present. It is expected to develop a cheap magnetic bearing system. A magnetic top consist of a couple of the ring shaped permanent magnets, abbreviate as PMs, seems to be a candidate for the passive magnetic bearing.

The purpose of this paper is to investigate the possibilities to build up a passive magnetic bearing composed of the ring shaped PMs, analytically.

2. Analysis of motion of a magnetic top

We had proposed a simple analytical method[1], instead of the previous precise analysis[2]. In this analysis, the ring shaped PMs, magnetized in axial direction, are simulated by the equivalent side current model. That is, a ring shaped PM is replaced by the set of circular coils located at the outer and inner surfaces of a ring shaped PM. The directions of currents in the outer and inner equivalent coils are inversed with each other, describing the axial magnetization of a PM. The magnetic forces acting on the levitating PM are calculated as the interaction between the equivalent side currents of the levitating PM and the magnetic field generated by the equivalent side currents of the ground PM.

We had obtained the useful results about the relations between the 'levitating area' where a magnetic top can maintain levitating and the dimensions of the PMs, based on the static analysis. In this analysis, three dimensional layout of the PMs and the tilt angle of the levitating PM were considered, but the effects of rotation of a levitating PM were neglected[1].

In this paper, the characteristics of a magnetic top are discussed based on the dynamic analysis. Three dimensional layout of the PMs, the tilt angle of a rotating PM and the mechanical inertia of the rotating PM are considered, but aerodynamic damping effects are neglected. The motion of a rotating PM is simulated based on the equation of motions about the angular momentum of the rotating PM, using the 4th order Runge-Kutta algorithm.

3. Simulated behavior of a magnetic top

Figures show the simulated trajectories of the bottom of the axis of the levitating magnetic top for 5 seconds. The outer diameter, the inner diameter, the thickness of the PMs are 30mm/12mm/5mm for the levitating PM, and 134mm/75mm/60mm for the ground PM, respectively. The mass of the levitating PM is 20.4g, and the equivalent currents are set as 286A/mm deducted by the measured magnetic field density at a surface of the PM. According to the previous analysis, the target point of the restoring magnetic force is $(x, y, z) = (0, 0, 99.5)$ mm in this model. The initial position and the tilt angle of the rotating PM are $(x, y, z) = (1, 0, 98.5)$ mm, 1 degree, respectively.

Figure (a), (b), (c) show the cases of rotating speed of 17, 1380 and 3240 rpm, respectively. The too low rotating speed is insufficient to maintain attitude of the top and results lack of levitation force as shown in Fig.(a). On the otherhand, the too high rotation speed generate the magnetic force larger than the restoring force resulting to fly out the top as shown in Fig.(c). The PM can maintain levitating in the levitating area as far as it rotates in a proper speed, as shown in Fig.(b).

4. Conclusions

In case of a magnetic top, it is difficult to repeat experiments in the same condition. However, the vertical and horizontal swaying frequencies, and size of the levitating areas are well in accordance with the analyzed values.

The following results can be obtained from the dynamic analysis in this paper:

- 1) A magnetic top, rotating in the axially symmetrical magnetic field, can be levitating by its precession.
- 2) The parameters to maintain levitation of a magnetic top are the tilt angle and the rotating speed.
- 3) In the model mentioned in this paper, the tilt angle should be about 1 degree, the rotating speed should be about 20 to 3200 rpm.

A magnetic top can be used as a rotating demonstration model in which some swaying motion can be permitted such as the toys or the relaxation items. The levitation area can be easily designed by the analysis proposed in this paper.

Design Considerations of Axial Ring magnet.

C. Li, M. Devine, G. Hatch
Dexter Magnetic Technologies, Hicksville, NY

Ring is one of the basic geometries of permanent magnet. It is widely used in magnetic lenses, MRI devices, mechanical devices and sensors. Ring type magnets with transverse field have been discussed extensively due to their applications in MRI devices. For some applications such as Faraday Optical effect, magnetron guns, and klystron applications, an axial field is required. The requirement for this axial field can be a maximum possible field per given geometry; a sinusoidal type field with homogenous field along the axis or a field varies along the axis in a sinusoidal form. This article will discuss the relationship among the dimensions of a simple axial ring magnet.

Magnetic Field between the two poles of an axial ring magnet

In this discussion, we consider a ring magnet with radius of R_1 and R_2 and length L .

The orientation is along the length. We use polar coordinates in this discussion with the origin located at the center of the ring. By solving the Laplace equation, we can get the scalar potential for the region between the two poles. Expanding the scalar potential along the axis at the origin, we can show that the field along the z direction is in the form of equation 1.

We can see that we only need the field along the axis in order to obtain the field at any point. And the field along the axis is readily available by calculating the field from the surface charges on the pole faces.

So we have the general expression of the magnetic field between the two poles as in equation 2.

Optimum length of the ring to get uniform field

For a uniform field in the center region, we omit the high order terms with the condition of $r \ll L$ and obtain the optimum length to achieve a uniform field at the center region between the poles as shown in equation 3.

For example, If we have a ring magnet with OD of 2.00 cm and ID of one cm, from equation 3, we have 1.746 cm for the length in order to get a uniform field. Figure 1 shows the field plot along the axis with N35 material.

Optimum length for a peak field at the center

If the diameters of the ring are given, and a peak field at the center is required, then we can get the optimum length by taking the derivative of the field at the center. It is shown in equation 4.

We again using the above magnet as an example. From equation 4, we have the optimum length for maximum field at center to be 1.0 cm. By varying the length, we plot the field at the center of the ring in Figure 2. It shows that the field drops when the length increases to more than one cm.

$$H_z = \sum_{n=0}^{\infty} -\frac{1}{n!} \frac{\partial^n}{\partial z^n} \left(\frac{\partial \varphi_{axis}}{\partial z} \right) r^n P_n = \sum_{n=0}^{\infty} \frac{1}{n!} \left(\frac{\partial^n H_{axis}}{\partial z^n} \right) r^n P_n$$

equation 1

$$H_z = \frac{B_r}{2} \left(\left[\frac{1}{\left(\frac{1}{4} + \frac{R_2^2}{L^2} \right)^{3/2}} - \frac{1}{\left(\frac{1}{4} + \frac{R_1^2}{L^2} \right)^{3/2}} \right] + \frac{1}{2} \left[-\frac{3R_2^2}{L^2 \left(\frac{1}{4} + \frac{R_2^2}{L^2} \right)^{5/2}} + \frac{3R_1^2}{L^2 \left(\frac{1}{4} + \frac{R_1^2}{L^2} \right)^{5/2}} \right] \frac{r^2}{L^2} P_2(\cos \theta) \right. \\ \left. + \frac{1}{24} \left(\frac{45R_2^4 - 15R_2^2 L^2}{L^4 \left(\frac{1}{4} + \frac{R_2^2}{L^2} \right)^{7/2}} - \frac{45R_1^4 - 15R_1^2 L^2}{L^4 \left(\frac{1}{4} + \frac{R_1^2}{L^2} \right)^{7/2}} \right) \frac{r^4}{L^4} P_4(\cos \theta) + \dots \right)$$

equation 2

$$L = 2 \sqrt{\frac{R_1^{4/3} R_2^{2/3} - R_1^{2/3} R_2^{4/3}}{R_2^{4/3} - R_1^{4/3}}}$$

equation 3

$$L = \frac{2R_2^{2/3} R_1^{2/3}}{\sqrt{R_2^{2/3} + R_1^{2/3}}}$$

equation 4

Introduction

Li₀ FePt has received many attentions in the field of permanent magnetism. The remarkable anisotropy and chemical stability makes it possible to be used as bio-compatible magnet. In order to enhance the magnetic performance, many efforts have been focused on the introduction of soft magnetic phase in FePt Li₀ matrix. By the strong exchange coupling between magnetic hard and soft phase, the energy density, (BH)_{max}, can be significantly increased as predicted by the exchange spring model by Kneller and Hawig [1]. Very high value of (BH)_{max} of larger than 40 MGOe has been reported in a nanostructured FePt-Fe₃Pt film prepared by multilayer deposition with ~60 nm in thickness [2]. For a single phase magnet, theoretical studies also have predicted that the (BH)_{max} can also be enhanced by the reduction of mean grain size [3]. However, experimental investigation concerning this subject is not widely. In this study, the focus was placed on the relation between microstructure refinement and magnetic properties in single phase Fe-Pt films.

Experimental

Single layer films with composition of Fe₆₀Pt₄₀ with thickness of 100~300 nm were deposited at different temperatures of 400 and 800°C on quartz substrates to create significant different mean grain size. Generally, the low-temperature grown FePt films contain certain residual disordered region. However, in this study, the effects from the residual disorder phase must be ruled out. Therefore, after sputtering, the deposition temperature was maintained for different time; 400°C for 15 hours and 800°C for 1 hour to complete the ordering transformation and homogenize the film, forming single phase of Li₀ with uniform extent of ordering. The phase structure was analyzed by x-ray diffractometry (XRD). The mean grain size was measured from the transmission electron microscope (TEM) images. Magnetic properties were measured by using a vibrating sample magnetometer (VSM) with a maximum applied field of 2T at room temperature.

Results and discussion

Figure 1(a) show the x-ray diffraction patterns of the films with various thicknesses annealed at 400 and 800°C. The order parameter (S_{ord}) for each sample was measured from the intensities of peaks in the pattern and corrected by chemical composition. To further verify if the films annealed at different temperature are single phase, the slow scan of (220) peak group were performed. The results show clearly separated two symmetric peaks of (220) and (202) from Li₀ phase as shown in Fig. 1(b) and 1(c). This confirms the films are with single phase of Li₀. The relation between grain size and film thickness for the films annealed at 400 and 800°C is shown in Fig. 1(d). It indicates that the grain size in the 800°C-annealed films roughly equal to double of the film thickness; on the contrary, it only increases 23% while the film thickness was increased from 100 to 300 nm in the 400°C samples. Composition distribution across the grain boundaries was analyzed using energy dispersion spectroscopy (EDS) nanobeam line scan, no segregation was found in the the films. Magnetic properties are summarized in Table 1. Films annealed at 400°C exhibit higher coercivities and remanences than that of samples annealed at 800°C. A significant enhancement of (BH)_{max} was obtained in the three different thickness films. The maximum (BH)_{max} was 19.6 MGOe for the

300 nm-thick sample annealed at 400°C, which is 72% larger than that of 800°C annealed film with same thickness.

The magnetic data in Table 1 indicate that the enhanced energy density is mainly from the higher coercivities, remanences and coercive squareness ratio (S^*).

Ordered FePt phase with nanogranular/island-like structure is one of the most potential candidates for application in magnetic devices and permanent magnets due to its large magneto-crystalline anisotropy constant (K_u) to resist thermal fluctuation [1-4]. None work has been focused on the relationship between the magnetization behavior and surface morphology of FePt (110) films. In this present study, we fabricated Fe/Pt multilayers with different thickness (t) on MgO (110) substrates, and the thickness dependence of the magnetization reversal behavior and microstructure in FePt L10 epitaxial films was studied. The relationship between the surface morphology, magnetic domains, and the grain size of Fe/Pt multilayers were also discussed. We are the first to report the intrinsic properties and magnetization behavior of the FePt (110) epitaxial films by adjusting the thickness to control the microstructure. FePt films composed of [Fe(1 nm)/Pt(1 nm)] multilayers with different thickness ranged from 8 nm to 40 nm were fabricated at 500 oC by molecular-beam epitaxy on Pt-buffered (10 nm)/MgO(110) substrates. Pt and Fe layers were deposited via e-beam evaporation at a deposition rate around 0.005 nm/s, respectively. The coercivity monotonically decreases from 9500 Oe to 2000 Oe as t changes from 8 nm to 40 nm and the easy magnetization axis lies in the [001] direction parallel to the film plane. The uniaxial magnetic anisotropy K_u increases with increasing t and shows a similar tendency following the slope of saturation magnetization (M_s). The K_u constant value ranged from 1.6 ($t = 8$ nm) to 2.8×10^7 erg/cm³ ($t = 40$ nm). If the growth temperature is higher, the K_u constant will close to the value of fully ordered FePt alloys (7×10^7 erg/cm³). With increasing thickness the isolated grains coalesce and connect to each other for $t = 10\sim 30$ nm. When t is over 30 nm, the FePt films fully cover with the whole surface, and the film changes from the island-like to continuous morphology. Strongly faceted islands of FePt particles are observed with regular-shape distribution as shown in inset of Fig. 1. FePt L10 rectangular-like islands are aligned along the direction of MgO [001]. The major facet planes are (1 - 1 0) and (001). It can be understood that with increasing film thickness, particles with multiple domain increases. The rotation of the magnetization is considered to be a dominating mechanism in the thinner films. The angular dependence profile of coercivity for the 34 nm thick FePt films shows a behavior closed to domain-wall motion. By reducing the thickness of FePt films, the angular dependence profile of coercivity becomes closed to the S-W rotation mode as shown in Fig. 1. The mechanism of the coercivity is associated with the surface morphology changed from isolated to continuous states. It indicates that strong exchange coupling exists in the thicker films and the disappearance of island structure causes the decrease of coercivity. However, the average size of magnetic domains increases with increasing film thickness. The isolated grains are less magnetically coupled in the rotation mode and the reversal of magnetization is more independent. It is originated from the weakening of domain-wall motion, while domain rotation is enhanced depicting a decoupling of inter-grain interaction. The separated grains are less magnetically coupled in the rotation mode and the reversal of magnetization is more independent as identified with ΔM measurement and initial magnetization curves as shown in Fig. 2. This work clearly showed the effect of surface morphology of FePt (110) films via thickness control on their magnetic properties. The in-

plane coercivity decreases with increasing film thickness, while uniaxial magnetic anisotropy, and average size of magnetic domains and grain size values increase with the thickness of FePt films.

Introduction

$L1_0$ CoPt and FePt thin films are commonly accepted as potential materials for future recording media with ultra high density exceeding 1 Tbit/inch² due to the very high Curie temperature and anisotropy. However, it remains limitations for manufacturing. One of the problems is the high processing (ordering) temperature (T_{ord}), which is necessary to form high anisotropy $L1_0$ phase. Although $L1_0$ CoPt exhibits higher anisotropic field, the T_{ord} about 100°C higher than that of FePt constrains its potential on recording application. Lowering the ordering temperature of CoPt therefore becomes an important issue which many efforts have been devoted to. Alloying of several low-melting-point elements including Pb, Sn, Bi, Ag, and B has been reported to be effective in reducing T_{ord} by creating defects or forming solid solution in CoPt grains [1]. Au/CoPt multilayer has also been reported to show lower T_{ord} than that of CoPt single layer [2]. However, the structural data and the mechanism is not discussed in details due to the intrinsically very strong (111) orientation which fails the monitoring of order transformation by the traditional θ -2 θ scan. In this paper, the ordering process of Au-underlayered CoPt was studied by χ rotation method using synchrotron radiation light source which gives direct information of ordering. Additionally, magnetic properties and morphology evolution were studied in details.

Experimental

Thin film samples were deposited by radio frequency (rf) magnetron sputtering under a background vacuum better than 2×10^{-7} torr. Two series of sample were prepared: CoPt layer on Corning 1737 substrate and Au underlayer with thickness of 50 nm deposited at room temperature. A sequential annealing was performed at 400~700°C for 30 minutes after deposition. The thickness of CoPt layer is 20 nm. Exact composition of the CoPt films was $Co_{46}Pt_{54}$. Structural analysis were carried out at National Synchrotron Radiation Research Center (NSRRC) beamline 17B with energy of 8 keV (wavelength, $\lambda = 1.55 \text{ \AA}$). In-plane magnetic properties were measured at room temperature using a vibrating sample magnetometer (VSM) with maximum applied field of 2 T. Surface morphology was investigated by scanning electron microscopy (SEM).

Results and discussion

Magnetic properties of the CoPt and Au/CoPt films are shown in Fig. 1(a) and 1(b). The coercivity (H_c) increased while the annealing temperature (T_a) exceeded 400°C for both CoPt and Au/CoPt films. As T_a reached 700°C, similar value of H_c (~12 kOe) were achieved for the two samples. Magnetization at applied field of 2T (M_{2T}) correspondingly decreased while T_a exceeded 400°C and reached a minimum at $T_a = 700^\circ\text{C}$. The temperature dependences of magnetic properties for the two films were similar, except a shift in T_a about 100°C. Figure 1(c) shows the x-ray diffraction pattern by χ -rotation method. It reveals that the CoPt film with $T_a = 500^\circ\text{C}$ still remain disorder structure; on the contrary, a clear peak of (001) indicates that the Au/CoPt film at the same condition has begun to order. Figure 2 shows the hysteresis loops and the corresponding SEM images for the CoPt and Au/CoPt films annealed at 500 and 600°C. The loop of Au/CoPt films with $T_a = 500^\circ\text{C}$ shows a stepwise shape indicating magnetic two-phase structure. This suggests the ordering is not complete. The SEM images show that the CoPt films remain continuous morphology even at $T_a = 600^\circ\text{C}$; however, the Au/CoPt film exhibits discontinuous phase separation structure (CoPt

grain embedded in the gold matrix) at $T_a = 500^\circ\text{C}$. Comparing the SEM results with the XRD data, it is interesting to notice that in the CoPt films, the occurrence of ordering accompanies grain growth and surface roughening; but in Au/CoPt samples, it accompanies the phase separation. This suggests that the mechanism of ordering at lower temperature in Au/CoPt film may involve the relaxation of internal strain or stress. The further investigations are undergoing.

The findings of this study can be summarized as follows: (1) the insertion of Au underlayer was found to reduce the ordering temperature by about 100°C; (2) formation of $L < L_0$ phase can be successfully monitored by χ -rotation diffraction; (3) the phase separation between Au and CoPt was found to assist ordering transformation.

Strain effect on the spin reorientation of epitaxial Nd-Fe-B films.

A. Kwon¹, V. Neu¹, V. Matias², J. Hänisch², R. Hühne¹, B. Holzapfel¹, L. Schultz¹, S. Fähler¹
 1. Institute for Metallic Materials, IFW Dresden, Dresden, Germany; 2. Los Alamos national laboratory, NM 87545, NM

While Nd₂Fe₁₄B is already used in high performance bulk magnets, thin films are interesting for applications such as microactuators, motors and magnetic recordings. For technological applications, well textured Nd₂Fe₁₄B films are available [1,2]. Nd-Fe-B has very high magnetocrystalline anisotropy, therefore, magnetoelastic anisotropy is usually neglected. However, in large external stress, especially spin reorientation transition at low temperature should be affected. Here a new approach to study the influence of huge strain on the intrinsic properties of Nd₂Fe₁₄B under uniaxial stress is presented.

Hastelloy, which has high ductility and cheap price, was used as a substrate to reach a strain up to 2% by conventional mechanical elongation which breaks the in-plane symmetry. In addition, this elongation gives uniaxial strain on the film. So one can expect with elongation direction, tensile stress is given and by poisson ratio the other directions have compressive stress (Fig.1). Prior to elongation, MgO(001) had been deposited by ion beam assistant deposition (IBAD). As a next step, Mo and Nd₂Fe₁₄B are deposited at 450 °C by pulsed laser deposition. In fact, Nd-Fe-B films on Cr/Ta buffer layers shows perfect texture so that spin reorientation transition looks like in a single crystal (Fig.2 (a)). Below the spin reorientation temperature (T_{SR}), in-plane magnetization increases as the magnetization lies along an easy cone. By the tetragonal crystal symmetry the in-plane symmetry is broken and the [110] direction exhibited a higher polarization compared to the [100] direction. However, whereas films on Cr/Ta are discontinuous, a Mo buffer results in a smooth and continuous Nd-Fe-B film [1] which gives possibility to analyze strain effect. On top of the IBAD substrate, Mo grows epitaxially with a (001) orientation and Nd-Fe-B films on top of these buffers posses the desired (001) out-of-plane orientation with 3 different in-plane orientations. Before elongation, no distinguishable polarization is observed when measuring along different in-plane orientations (Fig.2 (b)). After elongation, lattice parameter along the elongation direction increases and lattice parameter of the other directions decrease. This was measured by 4 circle diffraction on the Mo buffers as the intensity of Nd₂Fe₁₄B is too low to analyze strain in the film itself. When hastelloy was stained plastically by 2%, a total ~0.9% of in-plane strain in Mo is observed. By this, Nd₂Fe₁₄B has distinguishably elliptical distortion of the cone shape below T_{SR} (Fig.2(c)), significantly higher compared to the influence of the 4-folded crystal symmetry (Fig.2 (a)). However, temperature for the spin reorientation does not change due to the strain.

Nd₂Fe₁₄B alloy is a well-known material as a permanent magnet because of its high uniaxial magnetocrystalline anisotropy [1]. A lot of work has been extensively studied not only for bulk samples but also for thin film samples [2]-[4]. Since the easy magnetization axis of Nd₂Fe₁₄B thin film is easily aligned to out of the film plane. It has opened up varieties of possibility for the applications in more efficient micromagnetic devices, such as actuators and motors. However, detailed magnetization mechanism of this material is still unknown so far. In this study, in order to clarify the coercivity mechanism, the microstructure and magnetic properties of Nd₂Fe₁₄B films with Ta buffer layer has been investigated by changing the compositions and the film thicknesses.

The samples were prepared on a MgO(100) single crystal substrates using an UHV-compatible dc-sputtering apparatus. The base pressure is below 5×10^{-8} Pa. A Ta buffer layer of 20, 40 and 60nm were firstly deposited onto MgO (100) substrate at room temperature (RT). Then a Nd-Fe-B layer of 30nm was deposited at the substrate temperature in the range between 500 to 700°C. The magnetic properties were measured by a superconducting quantum interference device (SQUID) magnetometer. The structure characterization was performed by an X-ray diffraction with K α radiation. The film composition was determined by an electron probe micro-analysis (EPMA) to be Nd_{15.2}Fe_{70.2}B_{14.6}, Nd_{14.3}Fe₇₅B_{10.7} and Nd_{12.0}Fe_{83.3}B_{4.8} (at. %).

X-ray diffraction patterns of Nd-Fe-B thin films with various composition of Nd-Fe-B layer were shown in Fig. 1. The thickness of Ta buffer layer and Nd-Fe-B layer was fixed at 40 and 30nm, respectively. It is seen from this figure, the peaks from the c-plane of the Nd₂Fe₁₄B phase, such as 004, 006 and 008 were clearly observed for all the samples. Among them, remarkable intense peaks of the c-axis of Nd₂Fe₁₄B phase were observed for the samples with the composition of Nd_{14.3}Fe₇₅B_{10.7}. From the magnetization measurement, it is revealed that a maximum value of the coercivity H_c measured in the perpendicular direction was obtained for 11kOe at this composition.

This work was partly supported by Toyota Motor Corporation. The magnetization measurement was performed at Magnetic Material Laboratory at IMR, Tohoku University. The structural characterization was performed at the Hi-tech Research Center of Tohoku Gakuin University.

In field magnetic domain observation of Nd-Fe-B thin film by magnetic force microscopy.

T. Iwasa¹, H. Ishioka¹, H. Kato¹, T. Sato², T. Shima¹

1. Faculty of Engineering, Tohoku Gakuin University, Tagajo, Japan; 2. Toyota Central R&D Labs., Nagakute, Japan

Among all permanent magnets, Nd-Fe-B based magnets are currently the most powerful ones with the highest maximum magnetic energy product $(BH)_{\max}$ [1]. Nowadays, Nd-Fe-B magnets are used in a wide range of applications such as sensors, actuators and motors. The market for them is continuing to expand to hybrid vehicles as their magnetic characteristics. Also a lot of studies have been done not only for bulk samples but also thin films [2][3]. In order to develop high performance permanent magnets a detailed and fully understanding of the magnetization process of the rare earth based magnets are not only of fundamental interest, but also of technological significance. Magnetic force microscopy (MFM) is a convenient tool to observe the magnetic domain structure of the material [4]. Furthermore, in order to understand the magnetization process, in field magnetic domain observation is essential and important. In this study, detailed observation of in field magnetic domain structure of Nd-Fe-B thin film was performed by MFM equipped with an electromagnet which can apply in the direction perpendicular to the film plane.

The samples were prepared using a dc-magnetron sputtering system. The base pressure was less than 5×10^{-8} Pa. A Cr seed layer of 1nm and a Mo buffer layer of 20nm were deposited at the substrate temperature T_s of room temperature (RT). Nd-Fe-B layer was co-deposited with Nd, Fe and B at $T_s = 300^\circ\text{C}$. A Mo (in some cases, Cr) capping layer of 10nm was finally deposited to avoid the oxidation and then it was annealed in the range between 400 and 700°C for 1 hour.

The coersivity (H_c) measured in the perpendicular direction of this sample was 18.8 kOe. Atomic force microscope (AFM) and MFM images of Nd-Fe-B thin film are shown in Fig.1. Bright and dark contrasts in MFM image represent an upward and a downward magnetization direction. Applied magnetic field during this measurement was performed at 3kOe. It was confirmed that a roughness of the surface of this sample was relatively flat and that was less than 1.5nm. A remarkable maze-like domain pattern was observed in MFM image. It is seem from MFM image, different behavior of the magnetic domain structure was observed at the center region of the image. With increasing an applied magnetic field, the magnetic domain was easily changed in this region. This behavior is thought to arise from the multiple phases of the Nd-Fe-B thin films.

This work was partly supported by Toyota Motor Corporation. The magnetization measurement was performed at Magnetic Material Laboratory at IMR, Tohoku University. The structural characterization was performed at the Hi-tech Research Center of Tohoku Gakuin University.

Improvement in magnetic properties of PLD-made Nd-Fe-B thick film magnets.

M. Nakano¹, H. Takeda¹, F. Yamashita², T. Yanai¹, H. Fukunaga¹

1. Electronics and Electrical Engineering, Nagasaki University, Nagasaki, Japan; 2. Matsushita Electric Industrial Co., Ltd., Osaka, Japan

We have already reported the fabrication of isotropic Nd-Fe-B thick film magnets, which have coercivity, remanence, and (BH)_{max} values of approximately 1000 kA/m, 0.6 T, and 60 kJ/m³, respectively, prepared by the PLD method with a high deposition rate of approximately 90 microns/h[1]. In addition, an application of a 0.2 mm-thick Nd-Fe-B film on a Fe substrate to a milli-size motor was carried out as a practical usage. As the advancement in micro-machines such as small motors depends on magnetic properties of small size magnets, a further improvement in magnetic properties of film magnets is strongly required. According to the observation on microstructure for the previously reported films[1], the size of Nd₂Fe₁₄B grains ranged widely from 5 to 440 nm, and the average grain size was estimated at 150 nm, which suggests that refinement in grain size is a key technology to improve magnetic properties of the thick film magnets. It has also been reported that a use of additives such as Zr, Nb, Ga is effective to obtain homogeneous microstructure, and resultantly to increase remanence and coercivity for Nd-Fe-B based ribbons and HDDR powder[2][3][4], respectively. This contribution reports magnetic properties of the PLD-fabricated thick films prepared from Nd-Fe-B targets including Zr, Nb, Ga additives. Furthermore, the pulse annealing as a high-speed crystallization method was applied to the films including the additives. The targets with the composition of Nd_{2.6}Fe₁₄B + M_{0.5} at.% (M = Zr, Nb, Ga) and Nd_{2.0}Fe₁₄B + M_{0.5} at.% (M = Zr, Nb, Ga) and were prepared. They were ablated with a Nd-YAG pulse laser at the repetition rate of 30 Hz, and the films were deposited on Ta substrates. The distance between a target and a substrate was fixed at 10 mm, and the obtained thickness was larger than 20 microns. Before the ablation, the chamber was evacuated down to approximately 0.01 mPa with a molecular turbo pump. As-deposited films were amorphous, and, therefore, they were crystallized by annealing with an infrared furnace whose maximum output power was 8 kW. We set the annealing temperature, heating rate and holding time at 923 K, 400 K/min and 0 min, respectively, as the conditions of a conventional annealing (CA) method. In addition, we adopted a pulse annealing (PA) method, in which samples were instantaneously crystallized for 1.7-1.8 s as a high-speed crystallization method. After a sample was magnetized up to 7 T with a pulse magnetizer, magnetic properties were measured with a vibrating sample magnetometer which could apply a magnetic field up to approximately 1800 kA/m reversibly. All the post-annealed films were magnetically isotropic and, therefore, in-plane magnetic properties were shown in this article.

Figure 1 shows the coercivity values of PLD-fabricated Nd-Fe-B thick film magnets prepared from Nd_{2.6}Fe₁₄B + M_{0.5} at.% (M = Zr, Nb, Ga) targets followed by the CA and PA methods. It was clarified that an adoption of PA method as a high-speed crystallization one together with additives such as Ga showed the synergistic results for the enhancement in coercivity. As the cooperated effect of the PA method and additives causes a remarkable increase in coercivity, we can reduce the Nd content of a target. Therefore, we prepared the film magnets from Nd_{2.0}Fe₁₄B + M_{0.5} at.% (M = Zr, Nb, Ga) targets followed by the PA method. The obtained demagnetization curves are shown in Fig. 2. An increase in remanence by approximately 0.1 T could be achieved compared with those of samples prepared from Nd_{2.6}Fe₁₄B + M_{0.5} at.% (M = Zr, Nb, Ga) targets. It was also found that an addition of Zr, Nb and Ga is effective to increase the coercivity for the targets with stoichiometric composition. Resultantly, an enhancement in (BH)_{max} was successfully achieved and obtained (BH)_{max} value reached approximately 70 kJ/m³ for the both of Zr and Nb added films.

Electrodeposited Co-Pt-(P) thick films prepared by low temperature process.

T. Tomimatsu¹, M. Nakano¹, T. Yanai¹, N. Fujita², H. Fukunaga¹

1. Electronics and Electrical Engineering, Nagasaki University, Nagasaki, Japan; 2. Nara National College of Technology, Yamatokoriyama, Japan

The development of electrodeposited Co-Pt and/or Fe-Pt thick film magnets is expected to enable new applications such as micro-machines, because electrodeposition has a high material efficiency compared with a typical vapor deposition. In addition, a process in low temperature fabrication together with an increase in thickness for the deposited film is a key technology to advance electronic devices comprising with those films. Callegaro et al. have already reported the preparation of electro-deposited Co-Pt-(P) thin films for magnetic recording media and the coercivity of 438 kA/m without an annealing process [1]. This contribution reports a fabrication of electro-deposited Co-Pt films with P additive by low temperature process. We also achieved the increase in thickness up to 5 microns without deterioration of mechanical properties. Co-Pt films were prepared by electrodeposition using a plating bath, which contained 2 mM $\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2$, 3-5 mM $\text{Co}(\text{NH}_2\text{SO}_3)_2$, 40 mM $\text{NaH}_2\text{PO}_4\text{H}_2\text{O}$ and 20 mM $(\text{NH}_4)_2\text{C}_6\text{H}_6\text{O}_7$, respectively, together with the pH adjusted to 8 using NaOH at the fixed bath temperature of 333 K. Although the plating bath did not include $\text{NH}_2\text{CH}_2\text{COOH}$, the composition of the bath was similar to Callegaro's one [1]. ITO substrates, Pt sheets and Ag/AgCl electrodes were used as the cathode, anodes and reference electrodes, respectively. Electrodeposition was conducted potentiostatically at -1.0 V versus Ag/AgCl with a total charge ranging from 3 to 180 C/cm² using a potentiostat. The as-deposited films were magnetized under a pulse magnetic field of approximately 7-8 T. The composition of deposited films was evaluated with an energy-dispersive X-ray analyzer (EDX). The magnetization curves were recorded with a vibrating sample magnetometer (VSM). Figure 1 shows the thickness of Co-Pt-(P) films as the function of the total charge. The thickness increased with increasing the charge, and the maximum thickness reached 5 microns at the charge of approximately 180 C/cm². Evaluation on composition and magnetic properties for the as-deposited films were carried out. The content of Co could be controlled between 68 and 100 at. % by changing amount of $\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2$ in the bath and coercivity value of a film electrodeposited at $\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2 = 3$ mM, $\text{Co}(\text{NH}_2\text{SO}_3)_2 = 2$ mM, and $\text{NaH}_2\text{PO}_4 = 40$ mM was approximately 250 kA/m (see Fig. 2). As shown in Fig.3, coercivity decreased with increasing exposure temperature, which indicated that inner stress of the films due to the P additive is one of mechanisms for the enhancement in coercivity.

Some magnetic properties of YTiFe_{11-x}Si_xC carbides.

B. C. Cizmas¹, L. Bessais², C. Djega-Mariadassou²

1. Department of Physics, Transilvania University of Brasov, Brasov, Romania; 2. ICMPE, UMR7182 CNRS, Université de Paris XII, Thiais, France

The ThMn₁₂ (S.G. I4/mmm) structure of R-Fe intermetallics exist only for the pseudobinary RFe_{12-x}M_x systems, where M is a structure stabilizing metal, either d transition metals (Ti, V) or p elements (Si, Ga). The solubility of M is limited, as example around $x=1$ for Ti and $x=2$ for Si. Due to the enthalpy value associated with the formation of the Fe-M bonds Ti occupies the 8i sites and Si preferentially occupies the 8f and 8j sites. Consecutively, it is possible to modify the Si content for early stabilized compounds with small amounts ($x=1$) of Ti element in 8i sites. The ThMn₁₂ type structure shows interstitial sites in the 2b Wickoff position, which can be filled with carbon via solid-solid reaction. The Y(FeM)₁₂ intermetallics play an important role in the determination of the Fe sub-lattice contribution to the magnetism of isomorphous R(FeM)₁₂ intermetallics. This paper is devoted to the study of the structure and magnetic properties of YFe_{11-x}Si_xTiC compounds. The effect of carbonation is analyzed using for comparison our previously results for noncarbureted system [1].

The polycrystalline YTiFe_{11-x}Si_x alloys ($x = 0 - 2$) were prepared by induction melting method, annealed one week at 1273K and water quenched. The carbon insertion into the I4/mmm structure was performed by solid-solid reaction between the YTiFe_{11-x}Si_x compounds ground to <36 μ m powder size and an appropriate over weight of C14H10 powders, two days at temperature above 673 K. X-ray diffraction analysis was carried out operating with Cu-K radiation by means of a Bruker diffractometer. The Curie temperature (T_c) was measured on a differential sample magnetometer in a relatively low magnetic field of 100 mT. Parallel and perpendicular isothermal magnetization data at low temperatures (8-300K) on magnetically aligned powders were obtained with PPMS-Quantum Design magnetometer, in external magnetic field up to 6T.

The cell parameters and the cell volume of ThMn₁₂ structure increase after carbonation and decrease with Si content. For carbides, the a parameter decreases from 0.8577 nm down to 0.8488 nm and the c parameter from 0.4847 down to 0.4791 nm. It results that the unit cell volume V_0 decreases linearly with x with ratio -5.70×10^{-3} nm³/Si at. The volume expansion $\Delta V/V_0$ induced by carbonation, related to the initial cell volume decreases linearly from 3.04%, for $x=0$ to 1.33%, for $x=2$. The Curie temperature T_c of carbides decreases nonlinearly with Si content from 698K, for $x=0$ up to 578K, for $x=2$ (Fig. 1a). It results, upon carbonation T_c increases around 30.7% for $x=0$ and 14.4% for $x=2$. For $x>0.5$, a quasi linear correlation with ratio +4.84 is observed between $\Delta T_c/T_c$ and $\Delta V/V_0$.

The saturation magnetization values, M_s of YFe_{11-x}Si_xTiC at low temperature were determined by fitting the parallel magnetization isotherms $M_{par}(H)$ with the usual approach to saturation law. The saturation magnetization at 0K, $M_s(0)$ was determined by fitting the $M_s = M_s(T)$ curves. The average magnetic moment per atom, deduced from the $M_s(0)$ values decreases with x from 1.66 μ_B , for $x=0$ up to 0.94 μ_B , for $x=2$. The comparison with calculated values in the rigid band assumption, using the magnetic valance approximation (MVA) shows a strong ferromagnetism induced by carbonation (Fig. 1b).

The XRD patterns performed for magnetically oriented powder samples shows for YFe_{11-x}Si_xTiC a uniaxial anisotropy with easy magnetization direction parallel to c axis. In order to determine the anisotropy constants K_1 , K_2 and the recurrent anisotropy field B_a we have used the analytical interpretation, based on a statistical model of the perpendicular magnetization isotherms $M_{per}(H)$ and

applying a least-square numerical method. The obtained values at 8K are reported in Fig. 1c, in function of Si content. The K_2 values are very small around 0, but K_1 and B_a decrease nonlinearly with x from 1.84MJ/kg and 3.76T for $x=0$, to 0.65MJ/kg and 1.97T, for $x=2$.

We consider that the competition between the change in electronic structure upon Si substitution for Fe and carbon insertion and the dilatation of the crystal lattice upon carbonation are responsible for the magnetic properties behaviors of YFe_{11-x}Si_xTiC.

[1] C.B. Cizmas, C. Djega-Mariadassou, L. Bessais, "Influence of Si substitution on the structure and magnetic properties of YFe_{11-x}Si_xTi ($x<2$)," J. Magn. Magn. Mater., vol. 242-245, pp. 823-825, 2002.

Departamento de Electricidad y Electrónica, Universidad del País Vasco (UPV/EHU), Apartado 644, 48080 Bilbao, Spain

In previous works we have performed a systematic x-ray magnetic circular dichroism, XMCD, study at the rare-earth $L_{2,3}$ edges in $\text{R}(\text{Fe}_{1-x}\text{Al}_x)_2$ compounds.[1-3] Our results indicate that Fe contributes to the L_2 R XMCD and this contribution is associated with the Fe molecular field acting at the R sites. These findings give rise to an experimental method of direct observation of the T(3d)-R(5d) hybridizations, which govern the R-T interaction. However, in the case of diluted $\text{R}(\text{Fe}_{1-x}\text{Al}_x)_2$ compounds a proper knowledge of the magnetic behavior of the Fe sublattice is necessary in order to make full use of this result. Within this framework we have carried out a ^{57}Fe Mössbauer study through the $\text{R}(\text{Fe}_{1-x}\text{Al}_x)_2$ series.

In this work we present the ^{57}Fe Mössbauer study performed on $\text{Lu}(\text{Fe}_{1-x}\text{Al}_x)_2$ ($x = 0, 0.25$ and 0.50) at $T = 15$ and 295 K (Figure 1). This study has been complemented with ac magnetic susceptibility, $\chi_{ac}(T)$, measurements between 5 and 350 K with an exciting field of 4 Oe, and with exciting frequencies of 1, 9, 90, 476, and 1.368 Hz. We have also measured FC/ZFC magnetization vs. temperature curves, $M(T)$, between 5 and 350 K with an applied field of 4 Oe (Figure 2).

In LuFe_2 , both Mössbauer spectra consist of two sextets with intensity ratio 3:1 according to the presence of an easy magnetic axis along the [111] direction. [4] In the diluted compounds the Al atoms are randomly distributed over the 16d sites. The Mössbauer spectrum of $\text{Lu}(\text{Fe}_{0.75}\text{Al}_{0.25})_2$ at 295 K has been fitted with two symmetric doublets with relative intensities given by the binomial distribution. At $T = 15$ K, the $\text{Lu}(\text{Fe}_{0.75}\text{Al}_{0.25})_2$ Mössbauer spectrum shows the typical profile of a diluted compound. The spectrum has been fit with a model which considers that the Al atoms are randomly distributed over the iron sites. The $\text{Lu}(\text{Fe}_{0.50}\text{Al}_{0.50})_2$ spectra recorded at $T = 15$ K and $T = 295$ K are both a narrow paramagnetic doublet. In this case, due to the poorly structured profile of the spectra, they have been fitted with just one doublet.

In order to investigate the origin of the magnetic spectrum observed in $\text{Lu}(\text{Fe}_{0.75}\text{Al}_{0.25})_2$ at 15 K we have performed $\chi_{ac}(T)$ at different exciting frequencies and FC/ZFC $M(T)$ measurements (Figure 2). At high temperatures ($T \sim 300$ K for $x = 0.25$, and $T \sim 70$ K for $x = 0.50$) a peak is observed in both ZFC $M(T)$ and $\chi_{ac}(T)$ curves. Irreversible phenomena occur at temperatures below the maxima in $M(T)$, and a clear dependence with the exciting frequency is observed in the $\chi_{ac}(T)$ curves. Similar behaviour is observed at lower temperatures ($T \sim 45$ K for $x = 0.25$, and $T \sim 10$ K for $x = 0.50$); however, the low temperature peak in $\chi_{ac}(T)$ is almost frequency independent, which seems to indicate the existence of a spin-glass state. These results are in agreement with the existence of magnetic clusters with different sizes and different magnetic responses.

Consequently, the magnetic spectra observed in $\text{Lu}(\text{Fe}_{0.75}\text{Al}_{0.25})_2$ at $T = 15$ K indicates that the magnetic iron moments are blocked at that temperature. In contrast, the paramagnetic spectra observed in $\text{Lu}(\text{Fe}_{0.50}\text{Al}_{0.50})_2$ at $T = 15$ K indicates that the blocking temperature is lower than 15 K. This results suggests that the lower temperature process, which takes place at $T = 10$ K in $\text{Lu}(\text{Fe}_{0.50}\text{Al}_{0.50})_2$, is at the origin of the freezing of the magnetic moments although further work is in progress to determine the exact nature of the phenomena observed.

Magnetic properties of $\text{YCo}_x\text{Ni}_{3-x}$ compounds.

E. Burzo, R. Tetea, I. G. Deac

Faculty of Physics, Babes-Bolyai University, Cluj Napoca, Romania

The YCo_3 and YNi_3 compounds crystallize in a PuNi_3 -type structure. In the above lattice the 3d transition metal atoms occupy three types of sites. The cobalt and nickel magnetic moments are dependent on the characteristic environment of a given site. The neutron diffraction studies show values of cobalt moments of 0.55(3), 0.79(4) and 0.04(1) μ_B [1]. Very weak nickel moments were reported in YNi_3 , namely 0.057(3), 0.073(3) and 0.065(3) μ_B respectively [2].

The high field measurements performed on YCo_3 show the presence of two field induced successive transition at $B_1=60$ T and $B_2=82$ T [3]. These metamagnetic transition are believed to occur at different crystallographic Co sites and are considered to come from a special shape of density of state near the Fermi level.

By gradual substitution of cobalt by nickel in YCo_3 we expect that the magnetic behaviour of the pseudobinary compounds will be modified. The presence, in the same compound, of very weak nickel moments in addition to Co ones results in interesting magnetic properties.

The $\text{YCo}_x\text{Ni}_{3-x}$ compounds were prepared by arc melting the constituent elements in a purified argon atmosphere. The samples were heat treated in vacuum, at 950°C, for 10 days. The X-ray analysis shows the presence of one phase only, of PuNi_3 type. The lattice parameters are slightly dependent on composition due to nearly the same radius of Co and Ni ions.

The magnetic measurements were performed in the temperature range 5-900 K and external fields up to 9T. Above the Curie points, the susceptibilities were determined by using a Faraday type balance. Some magnetization isotherms, obtained for the compound having $x = 2.4$ are plotted in Fig.1. A transition towards a state having somewhat higher magnetization is induced by an applied field of 5-6 T, at low temperatures (5 K). The variation of magnetization above this transition is dependent on composition.

The increase of the magnetization at the critical field is of 0.012 μ_B ($x=2.7$), 0.07 μ_B ($x=2.4$) and 0.03 μ_B ($x=1.8$). We attribute these transitions to the nickel atoms whose magnetization's increase under the action of external field.

Similar transitions have been observed for cobalt in ThCo_5 where two states with different magnetizations are induced by an applied magnetic field [4]. In our case, the transition is not so sharp as in ThCo_5 . We attributed the observed behaviour to a distribution of exchange fields and consequently of the critical fields during this ferromagnetic-ferromagnetic type transition determined by the presence of both Co and Ni atoms in the lattice.

There is experimental evidence that in observed metamagnetic transition nickel is involved. The high magnetization state in YCo_3 is observed in fields more than one order of magnitude greater than experimentally observed in the present study. In our system the critical field is little dependent on composition even the exchange interactions decrease strongly when cobalt is replaced by nickel. Also, the observed changes in the magnetization is of the order of magnitude of nickel moment induced when replacing yttrium by gadolinium in YNi_3 [5]. In this case the mean value of nickel moment increase from 0.07 μ_B (Y) up to 0.15 μ_B (Gd).

The neutron diffraction studies performed on $\text{Er}(\text{Fe}_x\text{Ni}_{1-x})_3$ [6] show that Ni atoms prefer the 18 h sites. We suppose that a similar substitutional preference takes place in $\text{YCo}_x\text{Ni}_{3-x}$ compounds. We note that in PuNi_3 type structure the ratio of the atoms in h:c:b sites is 2:1/3:2/3.

In a first approximation we suppose that the nickel magnetic moment of h site in $\text{YCo}_x\text{Ni}_{3-x}$ is the same as that determined in YNi_3 (0.065 μ_B). In this case the nickel contribution to the magnetiza-

tion will be 0.019 μ_B ($x=0.3$); 0.040 μ_B ($x=0.6$) and 0.078 μ_B ($x=1.2$). By comparing the induced nickel moment in GdNi_3 , we expected an increase of Ni moment at the metamagnetic transition of the same magnitude as nickel moments in YNi_3 .

These agree with experimental data, except for the compound with $x=0.6$. Probably that in this case the high decrease of the exchange interactions, as evidenced by changes in Curie temperatures, will influence significantly the nickel moments.

If we suppose that the decrease of the nickel moment is proportional to the exchange field, from the value evidenced in compound with $x=0.3$, the induced moment will be about half than that expected, in agreement with the experimental data. The compound with $x=0.6$ seems to be nonmagnetic. The above behavior is analyzed in correlation with band structures.

Magnetostriction in $\text{Sm}_2\text{Fe}_{17}$ before and after nitrogenation.

H. Chen, J. Xu, Y. Zhang, H. Du, C. Wang, Y. Yang
Physics School, Peking University, Beijing, China

Introduction

The interstitial $\text{Sm}_2\text{Fe}_{17}\text{N}_3$ compounds have excellent intrinsic magnetic properties for permanent magnet applications [1][2]. The high Curie temperature (750K), high saturation magnetization (1.56T, 300K), strong uniaxial anisotropy (12T, 300K), and the high theoretical value of (BH)max (59 MGOe) have attracted much attention. The fundamental and application researches were proceeded extensively, relating to the study of crystallographic structure [3], substitution effects of Sm, Fe, or N by other elements, and different manufacture process to product SmFeN magnet, etc. However, no literature reported the magnetostriction in $\text{Sm}_2\text{Fe}_{17}\text{N}_3$. In this paper, we present a investigation of magnetostriction in $\text{Sm}_2\text{Fe}_{17}$ and $\text{Sm}_2\text{Fe}_{17}\text{N}_3$.

Experiments

The investigated $\text{Sm}_2\text{Fe}_{17}$ sample was produced by strip casting technique [4], similar to melt spinning, using a wheel speed of 1 m/s. The dimension of selected $\text{Sm}_2\text{Fe}_{17}$ plate is $10 \times 10 \times 0.3 \text{ mm}^3$. This sample was then annealed at 1323K for a week.

The investigated $\text{Sm}_2\text{Fe}_{17}\text{N}_3$ powder sample was bonded with epoxy resin, because the $\text{Sm}_2\text{Fe}_{17}\text{N}_3$ powders will decomposed into Sm nitride and $\alpha\text{-Fe}$ at temperatures above 873K. The dimension of bonded sample is $10 \times 10 \times 0.8 \text{ mm}^3$. The strain gauges were sticking on the sample's surface, parallel or perpendicular to the magnetic field. The measurements were carried out using a Wheatston bridge; the data acquisition and processing were proceeded by a computer. To eliminate the magnetic resistor effect and temperature effect of the strain gauge, the compensation strain gauge was sticking on a copper plate, and placed together with the sample.

Results and discussion

Fig. 1 shows the λ_{\parallel} -H hysteresis loop of $\text{Sm}_2\text{Fe}_{17}$. The λ_{\parallel} is negative, the value of it increases with increasing field. The $\lambda_{\parallel}(0)$ is -75×10^{-6} . The λ_{\perp} -H hysteresis loop of $\text{Sm}_2\text{Fe}_{17}$ is shown in Fig. 2. The λ_{\perp} is positive, the value of it increases with increasing field, and unable to obtain saturation at 2T field. The $\lambda_{\perp}(2\text{T})$ is 78×10^{-6} .

Fig. 3 illustrates the λ_{\parallel} -H hysteresis loop of $\text{Sm}_2\text{Fe}_{17}\text{N}_3$. The λ_{\parallel} is also negative. The curve shows a magnetic hysteresis. Fig. 4 displays the comparison of magnetostrictions of $\text{Sm}_2\text{Fe}_{17}$ before and after nitrogenation. It is obviously that the λ_{\parallel} is lower after nitrogenation, because of the nonmagnetic epoxy composition. The lower value at low magnetic field can be attributed to the anisotropy increase dramatically after nitrogenation. The saturation field has increased very much.

The negative magnetostriction may result in compress anisotropy, due to the inverse effect of magnetostriction. The magnetostriction anisotropy can be used in the SmFeN bonded magnet fabrications [5].

Magnetic properties of Zr-doped $\text{Lu}_2\text{Fe}_{17}$ single crystal and its hydride.

$\text{Lu}_2\text{Fe}_{17}$ might be considered as the representative of the Fe-sublattice in a very interesting group of magnetic materials, R_2Fe_{17} (R - rare-earth metal), with extremely delicate balance of ferro- (F) and antiferro- (AF) magnetic interactions (because Lu is non-magnetic metal) [1, 2]. Different substitutions in the R and Fe-sublattices as well as introduction of the light atoms (hydrogen) can affect this balance and lead to a change of the type of magnetic ordering. $\text{Lu}_2\text{Fe}_{17}$ is characterized by two types of magnetic ordering: ferromagnetic up to Curie temperature $T_C = 130$ K and incommensurate helical magnetic structure with the collinear arrangement of Fe moments in the basal plane below the Néel temperature $T_N = 274$ K. It was found that hydrogenation of $\text{Lu}_2\text{Fe}_{17}$ leads to a suppression of antiferromagnetism and induction of the ferromagnetic state with $T_C = 393$ K [3]. In present work, we studied the effects of substitution (Zr for Lu) and interstitial (H) atoms on magnetic properties of $(\text{Lu}_{1-x}\text{Zr}_x)_2\text{Fe}_{17}$ compounds.

Alloys with $(\text{Lu}_{1-x}\text{Zr}_x)_2\text{Fe}_{17}$ ($x = 0.2, 0.4$) nominal compositions were prepared by melting pure elements and attempt to pull single crystals by means of modified Czochralski method in a tetra-arc furnace was done. The X-ray powder diffraction and thermomagnetic analyses showed that the alloy with $x = 0.4$ is multiphase. For the $(\text{Lu}_{0.8}\text{Zr}_{0.2})_2\text{Fe}_{17}$ compound, the hexagonal crystal structure of the $\text{Th}_2\text{Ni}_{17}$ type was approved for the main (>90%) phase. Hence, the solubility range of Zr substitution for Lu in these compounds was determined as $x = 0 - 0.2$. Hydrogenation of $(\text{Lu}_{0.8}\text{Zr}_{0.2})_2\text{Fe}_{17}$ single crystal without powderization of the sample was successfully performed and magnetization along the principal axes of the initial compound and its hydride was measured in magnetic fields up to 5 T at 4.2 - 320 K.

Influence of substitution of Zr for Lu could be expected to be similar to the situation observed for a case of a substitution of the tetravalent Ce for Lu in $(\text{Lu}_{0.8}\text{Ce}_{0.2})_2\text{Fe}_{17}$ since Zr is tetravalent as well. In $(\text{Lu}_{0.8}\text{Ce}_{0.2})_2\text{Fe}_{17}$, ferromagnetism characteristic for $\text{Lu}_2\text{Fe}_{17}$ at low temperatures was suppressed and the AF ground state was observed with $T_N = 247$ K [4], i.e. lower than in $\text{Lu}_2\text{Fe}_{17}$. However, we found a completely opposite effect for Zr substitution: the AF state present in $\text{Lu}_2\text{Fe}_{17}$ at elevated temperatures is suppressed completely in $(\text{Lu}_{0.8}\text{Zr}_{0.2})_2\text{Fe}_{17}$. Zr-doped compound is found to possess a spontaneous magnetic moment of $34.1 \mu_B/\text{f.u.}$ in the ground state and has an easy-plane type of magnetic anisotropy in the whole range of magnetic ordering. The values of magnetic moment and anisotropy field in the ground state of $(\text{Lu}_{0.8}\text{Zr}_{0.2})_2\text{Fe}_{17}$ are practically the same as in $\text{Lu}_2\text{Fe}_{17}$, however the temperature of magnetic ordering is increased from 274 to 325 K.

There are two important factors which influence strongly the magnetic properties of the compounds studied: change of interatomic distances and the additional electron from the substitution atoms. The fact of importance of the change of interatomic distances is confirmed by the dramatic effect of the hydrostatic pressure which is found to enhance AF. Since the lattice parameters of $\text{Lu}_2\text{Fe}_{17}$, $(\text{Lu}_{0.8}\text{Zr}_{0.2})_2\text{Fe}_{17}$, $(\text{Lu}_{0.8}\text{Ce}_{0.2})_2\text{Fe}_{17}$ do not differ considerably, both the 4th electron and the anisotropy of the change of the lattice parameters (change of the c-parameter is assumed to influence stronger than the change of the parameter a due to presence of the Fe atoms in the 4f position – “dumbbells” along the c-axis) are important and determine the particular changes of magnetism upon substitution. Hydrogenation as one of the methods of a significant increase of the interatom-

ic distances leads to a similar development of magnetism of $\text{Lu}_2\text{Fe}_{17}$, $(\text{Lu}_{0.8}\text{Zr}_{0.2})_2\text{Fe}_{17}$, $(\text{Lu}_{0.8}\text{Ce}_{0.2})_2\text{Fe}_{17}$ compounds.

In $(\text{Lu}_{0.8}\text{Zr}_{0.2})_2\text{Fe}_{17}$, concentration of hydrogen content was determined by the volumetric method as 1.5 H at/f.u. Hydride $(\text{Lu}_{0.8}\text{Zr}_{0.2})_2\text{Fe}_{17}\text{H}_{1.5}$ has a spontaneous magnetic moment of $35 \mu_B/\text{f.u.}$ in the ground state and ferromagnetic structure in the whole range of magnetic ordering with T_C about 370 K, i.e. considerably higher than in parent compound. Hydrogenation of $\text{Lu}_2\text{Fe}_{17}$ and $(\text{Lu}_{0.8}\text{Ce}_{0.2})_2\text{Fe}_{17}$ crystals was also found to stabilize ferromagnetism in the whole range of magnetic ordering; and the ordering temperature was strongly increased.

The work is a part of the research project AVOZ10100520 and has been supported by grants GACR 202/06/0185 and GAUK 109-10/257015.

Synthesis of SmCo_5 compound has become a new advanced stage of development of hard magnetic materials. The highest coercive force (H_{ci}) was received for sintered Sm-rich (SmCo_{5-x}) magnets. Post sintering heat treatment (HT) including slow cooling from 1120 to 850°C and rapid cooling to room temperature increases H_{ci} from 0,1 to more than 3,5 T. According to X-ray diffraction data the changes of lattice parameters of SmCo_5 phase after aging at 1200–800°C revealed the increase of Sm content in SmCo_5 with decreasing temperature. The mechanism of Sm enrichment has not been determined yet. In recent years, the extended X-ray absorption fine structure (EXAFS) technique has been successfully applied to investigate the local atomic structure of alloys. In this work, we have investigated the local and crystalline structure of SmCo_5 phase in as-cast hypo- and hyperstoichiometric $\text{SmCo}_{5\pm x}$ alloys after different heat treatment.

Ingots with nominal composition of SmCo_x ($x = 5, 4.5, 4, 3.5$) were prepared by induction melting in Ar atmosphere followed by casting in an iron mould. The ingots were aged in a vacuum furnace in series at 1200°C for 2 h + 1000°C for 5 h + 900°C for 10 h. The phase identification was carried out by X-ray diffraction (XRD) using $\text{CuK}\alpha$ radiation. EXAFS spectra above the L_{III} -Sm and K -Co edges at 4 – 300 K were measured at the E4 beamline of HASYLAB (DESY, Hamburg, Germany) in transmission mode. EXAFS spectra analysis was performed with VIPER program.

Due to evaporation and oxidation process decreasing of Sm content takes place during HT. According to XRD data, after final aging the sample N1 ($x=5$) consists of the main SmCo_5 phase and minor rhombohedral $\text{Sm}_2\text{Co}_{17}$ phase. Sample N2 ($x=4.5$) consists of only SmCo_5 phase. Samples N3 and N4 ($x=4, 3.5$) consist of a mixture of SmCo_5 and two crystalline modifications (rhombohedral and hexagonal) of Sm_2Co_7 phase. Table presents the unit cell parameters of SmCo_5 phase for samples N1-N4 after different aging.

It can be seen that unit cell parameters of SmCo_5 phase of the sample N2 do not change with reduction of the aging temperature. Therefore, it is assumed that the composition of N2 corresponds to the stoichiometric SmCo_5 compound. At 1200-1000°C the hyperstoichiometric alloy N1 is contained within the homogeneity limits and represents the solid solution SmCo_{5+x} , enriched with Co. Aging at temperatures lower than 1000°C results in formation of the $\text{Sm}_2\text{Co}_{17}$ phase by decomposition of the SmCo_{5+x} solid solution below the miscibility gap. Precipitation of $\text{Sm}_2\text{Co}_{17}$ reduces Sm enrichment of solid solution, and after aging at 900°C the lattice constants of SmCo_5 phase are similar to those of sample N2. The unit cell parameters of SmCo_5 phase for samples N3 and N4 differ from those of N1-N2. The c value is below the stoichiometric one and does not change with decreasing temperature of aging, whereas a value exceeds the stoichiometric one and increases after aging at 900°C (see Table). These changes of lattice constants evidence the enrichment of SmCo_5 compound with Sm. Indeed, the changes in the composition from SmCo_5 to SmCo_{5-x} via the formation of high-density crystallographic shear planes were observed by TEM.

EXAFS function $\chi(k)k^2$ Fourier transform moduli representing qualitatively the radial distribution curves $F(r)$ are shown on Fig. 1.

EXAFS data analysis demonstrates that reduction of aging temperature leads to the decrease of static local disordering in all samples. At the same time transition from monophasic (N1-N2) to diphasic (N3-N4) causes significant redistribution of samarium local environment (Fig. 1). The

scale of changes reaches its maximum at N2-N3 transition. According to wavelet-analysis two nearest spheres of samarium local environment in all samples are formed by Co atoms only. Two-sphere model provides satisfactory quality of fitting in monophasic samples (N1-N2) whereas we had to use 3-sphere Co-Co-Sm model for diphasic alloys (N3-N4). This once again confirms Co atoms substitution with Sm in CoSm_5 lattice of Sm-enriched alloys (N3-N4).

In conclusion, EXAFS measurements and XRD study of the unit cell parameters of SmCo_5 phase in as-cast SmCo_5 based alloys after different heat treatment evidence the enrichment of the SmCo_5 phase with Sm by partial replacement of Co atoms by Sm.

Impact of Aluminium on the magnetic properties of RT2 compounds (R = rare-earth, T = transition metal) through the modification of the electronic structure.

R. Boada¹, J. Chaboy¹, M. A. Laguna-Marco^{1,2}, C. Piquer¹, F. Jiménez-Villacorta³

1. Física de la Materia Condensada, Instituto de Ciencia de Materiales de Aragón, Zaragoza, Spain; 2. Advanced Photon Source, Argonne National Laboratory, Chicago, IL; 3. SpLine / Spanish CRG (BM25), European Synchrotron Radiation Facility, Grenoble, France

The exact nature of the induced magnetic moments remains an open key problem into the understanding of the magnetic interactions in many magnetic systems. This is the case of the spin-polarization of the 5d states of the rare-earth in R-T intermetallic systems (where R denotes a lanthanide and T a 3d transition metal). The Laves phase compounds RFe₂ and RA1₂ exhibit ferromagnetic ordering. However, while the RA1₂ systems show ferromagnetism (FM) below 150 K, the magnetic ordering temperature varies between 550 and 650 K through the RFe₂ series. It is thought that the FM order in the RA1₂ compounds is exclusively due to the rare-earth ions within a RKKY interaction framework. By contrast, the magnetism of the RFe₂ results from the competition of the localized 4f magnetism of the rare-earth and the itinerant magnetism of the transition metal. The exact nature of the R-T interaction is not well accounted a priori by any theoretical model and only phenomenological descriptions addressing the critical role of the R(5d)-T(3d) hybridization have been reported [1-3]. The problem of characterizing the 5d states and of determining the exact nature of the R-T interaction becomes critical in the case of the R(FexAl_{1-x})₂ compounds.

In addition, one of the most peculiar phenomenon occurring in the Laves phase RT₂ compounds is the fact that in several cases the substitution of a magnetic T by a non-magnetic atom as Al induces ferromagnetic order [4]. This behaviour has been addressed to the modification of the 3d density of states (DOS) whose shape near the Fermi level, EF, is rather peculiar. Different hypothesis have been formulated to account for the impact of Al into the magnetic properties of RT₂ [6-8]. However, these interpretations do not take into account the change of the DOS near EF due to the Al substitution. By contrast, theoretical band calculations suggest that the strong hybridization between the T(3d) and Al(3p) bands modifies the shape of the characteristic peak of the DOS in such a way that upon increasing Al content N(EF) increases and the magnetic properties of the system are modified.

Aimed to shed light on this debate, we report in this work a combined magnetic and XAS study of the (RyR'_{1-y})(FexAl_{1-x})₂ compounds where R=Ho, Er and R'=Y, Lu. These new series of compounds have been tailored in such a way that the spin polarization of the 5d states due to the rare-earth and to the transition-metal is varied in a controlled way. Our main aim is to determine the relationship between the DOS modification induced by the substitution of Fe atoms by Al, and the change of the magnetic properties of these systems. To this end we have performed a detailed x-ray absorption spectroscopy (XAS) study of these compounds at the Fe K-edge and at the L1 and L3-edges of the rare-earth. Due to the element and shell selectivity of the XAS technique and the extreme sensitivity of the near-edge region of the absorption spectrum to the modification of the DOS, it is possible to address that differences in this energy region reflects the different magnetic state, as determined from a different DOS, while differences in the high energy region are linked to structural effects.

The analysis of the XANES spectra recorded at the Fe K-edge (see Fig. 1) indicates that when a magnetic rare-earth is substituted by a non-magnetic one (Y or Lu) for a fixed Fe content, no significant modification of the near edge region is observed. By contrast, the Fe K-edge is strongly changed upon substitution of Fe by Al. These results indicate that in the former case the modifica-

tion of the magnetic properties of the systems is due to a simply dilution of the magnetic moment of the rare-earth. However, Al influences the magnetic properties of the compounds by modifying the DOS and then this effect has to be incorporated in order to account for the magnetic properties of the Al substituted systems. Similar results are found at the rare-earth L1-edge whose near edge region reflects the R-T hybridisation [7]. Consequently, the combined analysis of the XAS recorded at different edges indicates that the observed modification of the magnetic behaviour is due to the influence of Al into the peculiar DOS of the system. The expected results should gain insight into the origin of induced magnetic polarization in the 5d states and to assess the importance of RKKY interactions and R(4f)-R(5d)-Fe(3d) hybridisation in mediating the magnetic coupling.

A History of Magnetic Recording Areal Density Improvements — A Transducer Perspective.

R. Fontana

IBM Almaden Research Center (retired), San Jose, CA

Over the last 30 years, the areal density of magnetic recording disk products increased from 6 Mbit/in² (1978) to 200 Gbit/in² (2007) or a factor of 30,000. During this period, the transducer or head, i.e. the component that writes bits onto the disk surface and that reads the presence of these bits by detecting the stray fields from the written bit, evolved from a yoke structure with discrete wound coils and machined (i.e. sawed) and glued ferrite poles to today's lithographically intensive thin film processed devices with separate elements for reading and writing operations. This paper will describe the evolution of the magnetic recording head structure over these last 30 years and will discuss 1) how the introduction of MR and GMR films for sensing written bits with smaller area and 2) how the ability of the transducer to write bit cells having a sub-lithographic dimension along the written track, i.e. bit pitch, and a continually narrower dimension along the track pitch changed the areal density landscape for magnetic recording.

Table I illustrates the bit cell and head dimensions for magnetic recording in comparison to semiconductor processing minimum features over the last 30 years. Dramatic annual increases in magnetic recording areal density were achieved between the 1990 and 1996 time frame due to the introduction of MR films and even more dramatic changes in areal density were achieved between 1996 and 2002 due to the introduction of GMR films. These areal density increases were achieved because the high sensitivity of the GMR films allowed for the detection of smaller bit cells, in particular bit cells formed with successively narrower track pitches.

The impact of GMR films on magnetic recording areal density is better illustrated in Figure 1 where a history of the bit cell size for magnetic recording, DRAM, SRAM, and NAND flash is plotted. Note that in the early 1980's the bit cell area for magnetic recording, DRAM, NAND (or the EPROM equivalent) were essentially equivalent and remained comparable until 1991. Nine years later in 2000, after the introduction of first MR films (1991) and then GMR films (1998) for sensing the presence of bit cells, the area of magnetic recording bit cell was a factor of 6 – 7 smaller than comparable silicon based memory cells.

In sum, this paper traces the evolution of the read/write transducer used in magnetic recording over the last 30 years with particular emphasis on the impact of lithography and GMR films.

YEAR	1978	1990	1996	2002	2007
Areal Density (Gbit/in ²)	0.006	0.073	1.00	63	200
Bit Cell Area (μm ²)	100	8.5	0.6	0.01	0.003
Track Pitch (μm)	30	14	3.3	0.35	0.15
Bit Pitch (μm)	2	0.6	0.18	0.043	0.02
Bit Aspect Ratio	25	23	18	8.0	7.5
Yoke Width (μm)	40	11.2	2.6	0.28	0.12
MR Width (μm)	NA	7.0	1.65	0.17	0.075
IC Minimum Feature (μm)	3.0	0.6	0.22	0.08	0.05

The Spin Valve GMR Sensor.

B. Gurney

San Jose Research Center, Hitachi Global Storage Technologies, San Jose, CA

In this presentation I will discuss the spin valve giant magnetoresistance sensor that helped propel the hard disk drive industry to unprecedented areal density growth over the last decade. The advent of the spin valve sensor introduced a class of magnetic devices with a free and a pinned ferromagnetic layer that has become the standard for numerous sensor designs and a useful tool in many scientific investigations.

Around the time of the discovery of GMR by Albert Fert and Peter Grunberg the recording industry was on the verge of introducing a recording head with separate write and read elements where the reader used anisotropic magnetoresistance (AMR~1%). Could GMR (GMR~5-50%) be used instead? The ensuing flurry of research (that continues today) resulted in a much more sensitive recording sensor (Fig. 1) well suited to the 1-200 Gbit/in² areal density where it has been used, and led to a much deeper understanding of transport in ferromagnetic and layered materials.

The spin valve structure grew out of studies of Fe/Cr and Co/Cu multilayers when the origin of GMR was first being elucidated. These multilayers yielded high MR but required thick stacks and high saturation fields. What was needed was a sensor that would produce a high signal, low noise, a linear response in a few Oe field and also be compatible with the size and environmental constraints of recording. The spin valve successfully met those requirements and was introduced in products in 1997.

The basic structure (Fig. 2) derives its signal from the sharing of electrons between two ferromagnetic (F) layers separated by a conducting spacer. Spin dependent scattering in the bulk and at the boundaries of the F layers leads to an overall conductance that is different when the F layer magnetizations are parallel versus antiparallel. Control of the magnetization in the layers is an important feature of the structure where electrostatic, interlayer and current induced fields balance to properly orient the free layer and exchange anisotropy is used to fix the pinned layer direction. The need for strong pinning generated considerable research which led to the discovery of new antiferromagnets and a deeper understanding of exchange anisotropy.

Following the spin valve's introduction there was an explosive growth of new structures and improvements because layered structures provide many more degrees of freedom compared to a single alloy layer. Engineering of the interfaces by growth or by nanolayering with additional materials, control of scattering at the outer boundaries of the structure, improved pinning using a synthetic antiferromagnetic structure, and dual spin valves are a few examples. To investigate new structures significant changes in sputtering technology were needed including introduction of multiple target systems, higher quality vacuums and control of layers to the submonolayer level. The spin valve concept of responsive free layer and fixed pinned layer has been extended to other phenomena and devices, including tunneling magnetoresistance sensors that are now replacing GMR in disk drives and current perpendicular to the plane GMR structures.

More than 5 billion spin valve GMR heads have been used in hard disk drives. Along with other improvements in recording, they have made possible areal density increases between 60% and 100% per year (Fig. 3) bringing unprecedented storage capacity to customers, and helping to herald the age of the internet and pervasive digital video storage.

GMR spin valves, tunneling magnetoresistive devices, and beyond: transport, magnetism, and materials science.

*O. Heinonen, E. W. Singleton, B. W. Karr, Z. Gao, H. Cho, Y. Chen
Seagate Technology, Bloomington, MN*

The rapid increase in areal density storage capacity in magnetic hard disk drives over the past decade has, to a large extent, been enabled by advances in reader technologies. The discovery of giant magnetoresistance (GMR) [1] led to rapid development of current-in-plane (CIP) spin valve sensors [2] and directly resulted in an annual growth rate of areal density exceeding 100%. More recently, tunneling magnetoresistive (TMR) devices, with even higher signal than spin valves, have begun to replace GMR spin valves in disk drives.

In this presentation, we will review the underlying physics of spin valves and tunneling readers with an emphasis on the interplay between transport, magnetism, materials properties, and signal-to-noise ratio (SNR). For spin valves, we will examine the effects of bandstructure matching of the majority and minority spin channels of the ferromagnetic (FM) layers with the conduction bands of the normal metal (NM) spacer, and the effects of interfaces. Much improvement in the performance of spin valves came from carefully analyzing and engineering materials properties for optimal transport and magnetic performance, for example the use of synthetic antiferromagnets with Ru interlayers [3], surfactants for improved NM spacer and NM-FM interface properties [4], and specular capping layers [5]. All these impressive achievements in materials science brought the GMR ratio of sheet films up to about 20%.

The hard drive industry turned more recently to TMR devices for improved signal properties and because the heat dissipation in CIP spin valves became a problem as the devices were further scaled down in size. Initial efforts were focused on TMR devices with aluminum oxide barriers. In these devices Al is typically deposited on the CoFe electrode, and subsequently oxidized. The oxidation process both has to draw Al out from the CoFe electrode, and uniformly oxidize the Al without over- or under-oxidizing. Over-oxidizing leads to formation of Co oxides and the TMR signal rapidly degrades. Under-oxidizing leaves metallic Al pinholes which shunt current and degrade the TMR signal. For these reasons, it is difficult to achieve uniform Al oxide barriers with suitably low resistance-area product.

Other early barrier materials were HfO_2 and Ti oxide (non-stoichiometric). HfO_2 barriers gave a relatively low TMR signal, about 12%, but provided a very uniform barrier with TMR ratio maintained down to thinner barriers than for Al oxide. A peculiar property of HfO_2 is also that at the thinnest barrier thickness at which TMR is observed, the inter-layer exchange coupling between the FM electrodes is anti-ferromagnetic. While this further pointed to excellent interface properties, it made for poor TMR devices, as the inter-layer exchange conspired with magnetostatic interactions to give the sensors poor symmetry properties. Ti oxide, on the other hand, provided a larger signal (~19%) for even thinner barriers than HfO_2 or Al oxide, with a weak ferromagnetic interlayer coupling. This paved the way for reliable, high-SNR devices, which were subsequently put in to production. More recently, MgO -based [6] TMR devices, with TMR ratios exceeding several hundred percent, have been developed for hard drive applications. Much of the physics and materials science developed for CIP spin valves and earlier tunneling readers could be leveraged for rapid development of functioning MgO -based tunneling devices.

Ultimately, TMR readers will have to be replaced by devices with lower resistance-area (RA) product. Even at an RA of $1 \Omega\text{-}\mu\text{m}^2$, the resistance of tunneling readers will become prohibitive. Furthermore, the noise in TMR readers – shot noise, thermal magnetic noise, as well as spin-depend-

ent noise caused by spin-momentum transfer – scales poorly with diminished devices size and degrades the reader SNR. Currently under development are metallic current-perpendicular-to-plane (CPP) spin valves as well as current-confined-path CPP spin valves. These latter devices provide an RA product intermediate between all-metallic CPP spin valves and TMR readers, while maintaining high SNR.

GMR and TMR Sensors for non-storage applications.

M. Ruehrig, G. Rieger, J. Wecker

Corporate Technology MM1, Siemens AG, Erlangen, Germany

Less than a decade after the breakthrough discovery of the GMR effect by Grünberg and Fert [1] the new effect was sufficiently perfected and controllable to be introduced in most advanced commercially available products. Incorporating GMR spin valve sensors [2] and its technologically closely related counterpart TMR in cutting edge technology hard disk drives until today fuels the incomparable scaling law which keeps driving the magnetic recording industry towards ever higher recording densities.

Much less dramatic, though, was the influence of the GMR respectively TMR technology in other magnetic sensor applications. Although the potential to replace existing technologies like AMR or Hall sensors was soon realized after the discovery, GMR sensors until recently hardly gained significant market share in automotive and industrial applications.

Siemens started its GMR development for automotive and industrial applications soon after the breakthrough discovery as early as 1991. While focussing first on high signal exchange coupled multilayer systems, the potential of highly sensitive spin valve sensors was soon realized. In 1997 the first commercially available angular spin valve sensor in a crossed full bridge arrangement based on a proprietary reference layer system [3] was introduced to the market [4].

This system which is called AAF (artificial antiferromagnet) or SAF (synthetic antiferromagnet) reference system not only allowed a significant improvement of the thermal stability of the reference magnetization with enough rigidity against external disturbing magnetic fields, it also significantly reduced disturbing (magneto static) field interactions with the measuring layer due to the partially compensated net magnetic moment of the reference layer. Based on this concept a full sine-cosine Wheatstone bridge sensor was developed and marketed first by Siemens and afterwards by Infineon.

More recently the underlying concept was successfully transferred to the development of spin valve like TMR sensors [5] which are expected to gain significant importance due to the potential for higher MR signal, better thermal stability, improved sensitivity and beneficial scaling behaviour.

Today spin valve systems with exchange biased reference systems are state of the art. However, in many technologically relevant areas bridge arrangements are needed which are not so straightforward to be realized in exchange biased reference layer systems.

This paper will give an overview on non-storage GMR and TMR sensor applications by discussing the basic requirements for position, speed, angular, field and current measurements. For selected examples we will discuss options to tailor the sensor response curve by magnetic stack design with special focus on automotive and industrial applications.

New ideas for sensor bridge arrangements will be presented together with new readout schemes for TMR sensors.

The SIEMENS activities in GMR respectively TMR sensor development were partly funded by the German federal ministry for education and research (BMBF) and the European Union via RTN NEXBIAS, ULTRASMOOTH and SPINSWITCH

Spintronic devices for memory and logic applications.

B. Dieny, R. Sousa, G. Prenat

SPINTEC, CEA/CNRS/UJF/INPG, Grenoble, France

Giant magnetoresistance[1] found its first application in magnetoresistive spin-valve heads for hard-disk drives[2]. Low field magnetic sensors for position encoders were also developed based on this technology[3] as well as MRAM using pseudo spin-valves[4].

Later on, the observation of large magnetoresistance at room temperature in magnetic tunnel junctions (MTJ)[5,6] opened new prospects of applications. Thanks to the current-perpendicular-to-plane geometry, new MRAM architecture could be conceived allowing reaching much higher density than in earlier spin-valve MRAM designs[7]. The first generations of MRAM design were based on field induced switching with its improved version named "toggle switching"[8]. Freescale launched a first 4Mbit MRAM product based on this technology in 2006.

The discovery of the possibility to manipulate the magnetization of magnetic nanostructure by a spin-polarized current constituted another major breakthrough in the development of spintronics. Berger already observed in 1982 that electrical currents could have a direct influence on the propagation of domain walls[9]. However, it is the prediction[10,11] and observation[12] of the possibility to switch the magnetic configuration of spin-valves or MTJ which triggered a considerable interest of the scientific community for these so-called spin-transfer effects. This effect provides a new way to write information in magnetic nanostructures and especially MRAM. The advantages of using spin-transfer writing in MRAM are a better scalability of MRAM design, lower power consumption and better write selectivity[13,14]. In addition, thermal assisted write schemes combined with either field or spin-transfer writing were proposed, offering the ultimate scalability in MRAM design[15]. Intense R&D efforts are in progress in large companies as well as start-ups to bring these advanced MRAM designs to production.

Besides memory applications, the combination of CMOS components with embedded MTJ in above-IC technology allows conceiving all sorts of innovative hybrid logic devices such as reprogrammable logic gates in which MTJs are used as variable resistance influencing the switching threshold of the CMOS circuits. Innovative architecture of complex electronic devices can also be conceived in which logic and memory are much more intimately intertwined than with CMOS only components.

In an historical perspective, the talk will review these present and future developments.

SPINTEC's activity of this topic was partly funded through ANR PNANO CILOMAG and European RTN SPINSWITCH.

A dynamic scratch test to study read/write head degradation due to head disk interactions.

A. Wallash¹, H. Zhu¹, D. Chen²

1. Advanced Technology, Hitachi GST, San Jose, CA; 2. Mechanical Engineering Department, UC Berkeley, Berkeley, CA

As the head-disk spacing is reduced to increase areal density in hard disk drives, the likelihood of head-disk interactions increases. When these head-disk interactions involve direct contact to the read or write transducers at the air bearing surface, magnetic performance degradation is possible due to wear, mechanical deformation, or changes in stress induced magnetic anisotropy.

A dynamic scratch test is described to produce and study head degradation. Key features are the use of customized “nano-defects” on the disk, and a Guzik XY spin stand with a special *in situ* quasi static (QST) transfer curve measurement.

Disk indentations, scratches or embedded diamond or TiC particles were produced using a CSM NanoScratch tester with *in situ* AFM. Figure 1 shows examples of a progressive load scratch (left), an indentation (center) and an embedded diamond particle (right). The scratch and indentation were made using a Rockwell conical spherical diamond tip with a radius of 10 μ m. The height of the “pile-up” around the scratch or indentation is a function of the normal force, or load, of the diamond tip. The pile-up around the scratch/indentation is what hits the reader and writer while flying. To embed a particle into the disk, a single diamond particle, with a radius of 0.6 μ m, was pushed into the disk using a flat, 10 μ m x 10 μ m diamond tip until only 50nm protruded above the disk surface. Using these techniques, a large variety of defect shapes, heights and hardness can be made by varying the diamond tip radius, normal load profile, media substrate and particle size and type.

Magnetic head performance was measured before and after sweeping the read/write transducers repeatedly across the defect on the disk. Results are presented that compare the robustness of GMR and TMR head designs to head degradation caused by head disk interactions.

Figure 2 shows the QST transfer curves for a GMR read sensor after each sweep across the progressive load scratch shown in Fig. 1. Note the abrupt slope reversal, or “pin flip” after the 28th sweep across the defect, the flip back after sweep 43, and other dramatic changes in amplitude and asymmetry. The pin flip is explained by a reversal of the pinned layer in the GMR stack due to mechanical stress changes, and is remarkably similar to that caused by electrostatic discharge [1]. Other forms of read sensor head degradation, such as magnetic instability, will also be reported.

Figure 3 shows the resistance of a TMR sensor vs. sweep number over the hard, embedded diamond particle shown in Fig. 1. Failure analysis indicates that the abrupt resistance decrease after the 3rd sweep across the embedded particle is due to smearing/shorting of the tunneling barrier at the air bearing surface. Further sweeps “lap” away the smear and result in a partial recovery of the resistance. While no pinned layer flipping was observed in TMR heads, they were more easily degraded by head disk interactions that cut through the carbon overcoat on the head. In contrast, the GMR design exhibited pin flip but did not show the abrupt resistance decrease.

Figure 4 shows two Auger SEM images of the air bearing surface of two heads after the scratch testing. Brighter regions indicate wear of the carbon overcoat, confirming contact directly to the read/write transducers.

Changes in track averaged amplitude (TAA) and overwrite due to write head degradation, as well as wear of the carbon overcoat (COC) on the head and of the disk defects, will be discussed.

It is concluded that dynamic scratch testing provides valuable information about the strengths and weaknesses of the read/write transducers during head disk interactions, as well as wear characteristics of disk defects and the COC on the head.

Effect of Segregant Surface Energy on PMR Media Roughness.

Q. Dai, H. Do, K. Takano, B. Marchon
Hitachi GST, San Jose, CA

Introduction

Recently the HDD industry has migrated to Perpendicular Recording (PMR) for higher areal density [1]. PMR technologies used thus far generally relied on media with small, well-segregated grains separated by amorphous oxide grain boundaries such as SiO₂ [2]. Up to now, however, the selection of the oxide for the grain boundary appears to be mostly empirical process. The materials choice and its implication on magnetic performance as well as on the tribological consequences are not well understood.

In the present paper, we will report detailed examinations of PMR media made with various oxides as segregants. The focus is the impact of the oxide property on resulting media roughness. We will demonstrate that oxides that facilitate the formation of small grains will also be more likely to form rougher media, leading to overcoat coverage difficulty.

Experiments

To study how oxides affect the PMR media grain growth and resulting media roughness, we have carried out experiments using a variety of oxides varying in surface energy as well as in heat of formation [3, 4]. The heat of formation gives an indication of the stability of the oxides. Surface energy of the oxides, on the other hand, may affect the overall grain structure. Table I shows the oxides used in the investigation, and the corresponding heat of formation and surface energy values. Disk samples were made such that all layers have the same thickness and composition, with the exception of the oxides.

Results and Discussions

Fig. 1 shows the corrosion susceptibility of media made with the oxides shown in Table 1, as a function of surface energy. The maximum anodic current of the media was used as a gauge of the overcoat coverage, which in the present experiment is affected only by the roughness. It is observed that as the oxide surface energy increased from V₂O₅ to ZrO₂, the anodic current of the corresponding sample actually became lower. This indicates that the resulting media became smoother, and thus less likely to corrode. Although not reported here, we have observed that as the surface energy of the oxides decreased and the corrosion results deteriorated, the jitter noise actually decreased, possibly indicating smaller grains were achieved.

The inverted relationship between magnetic performance and the corrosion susceptibility is not surprising. It is likely that low surface energy oxides are better candidates for stabilizing small grains, analogous to the role of surfactants. At the same time, the low surface energy segregant may lead to media with higher roughness, leading to coverage difficulty.

AFM measurements shown in Fig. 2 support the above hypothesis. The maximum valley depth of the finished media is captured and plotted against the surface energy of the oxides used in these samples. It is clear that the lower the surface energy, the deeper the valley between grains. The result is consistent with those shown in Fig. 1, where as the valley depth increased, the anodic current also increased. In the full paper we will discuss in detail our understanding of the effect of segregant surface energy on the structure and how it might impact media roughness.

Stress Induced Permanent Magnetic Signal Degradation of PMR System.

S. Lee¹, S. Hong¹, N. Kim¹, J. Ferber¹, X. Che¹, B. D. Strom²

1. Samsung Information Systems America, San Jose, CA; 2. Apple Inc., Cupertino, CA

In the past, investigations of scratches have been notoriously difficult for lack of control in producing the scratches, and for the difficulties in finding and characterizing the micrometer scale scratches [1]. Both challenges have been overcome in this investigation. As a result, the study has revealed several important characteristics of the way media responds to scratch stress. Design guidelines for improved media designs follow from these revelations.

First, we found that PMR media is more sensitive to scratch stress than LMR media, both in its mechanical response and in the way that recorded magnetic patterns are affected. Fig. 1(a) shows the penetration depth of the tip measured while scratching and the residual scratch depth (measured after scratching) for PMR media using Hysitron nano-scratch system. Also shown in Fig. 1(a)) is the interface between DLC and the media layers before deformation. This Figure illustrates the relative elastic versus plastic response of the media at various loads. Of particular note is that the 20 μ N load produced penetration (residual) depth of 4.0nm (0.9nm), yet induced partial magnetic erasure. Both the severity of erasure and its width increased with load. Fig. 1(b) shows the residual depth after scratching for PMR and LMR media samples, as measured by AFM. Except at the highest loads, the PMR media shows greater residual depth, indicating greater plastic deformation of the media multilayer structure. The strength of this conclusion rests on the technique of applying the same stress to both media types, and analyzing the media in the same fashion. This conclusion raises serious concerns about PMR media reliability.

Second, we found that wherever residual “scratch” damage was observed, the magnetic patterns recorded on the media were damaged also. This observation is in contrast to earlier observations of magnetic patterns remaining undisturbed after mechanical “indentation” [2]. We attribute the difference to the material stresses and strains caused by friction during scratching; these friction stresses are absent during indentation. In particular, plastic strain in the ferromagnetic recording layer destroys its capacity as a memory medium. TEM cross section image of damaged PMR media was shown in Fig. 2 when 50 μ N load was applied during nano-scratch test. Damaged magnetic region turned out to be not re-writable possibly due to grain orientation change.

One more important observation is that the extent of permanent damage to magnetic patterns is broader than the apparent residual mechanical damage after scratching. This observation is consistent with the theory that plastic strains in the ferromagnetic layer result in magnetic degradation. These sub-surface strains are not always apparent from the surface morphology.

Finally, this investigation has led to a new development in media design. Rather than focusing on improving structural properties of protective overlayers (i.e. DLC and lubricant layers), the aforementioned observations suggest that strengthening the magnetic films would lead to greater scratch robustness for the media. Further improvements can be achieved by mechanically optimizing hardness of intermediate layer and soft magnetic underlayer so that mechanical stress cannot be concentrated on magnetic layer itself during head-disk interface contacts. Such approaches will facilitate the integration of PMR media while maintaining reliability of the HDD products.

Scratch Induced Demagnetization of Perpendicular Magnetic Disk.

M. Furukawa, J. Xu, Y. Shimizu, Y. Kato
Central Research Laboratory, Hitachi, Ltd., Fujisawa-shi, Japan

1. Introduction

The magnetic recording density of hard disk drives (HDDs) increases every year. To achieve this, HDD head/disk spacing has been reduced. In addition, perpendicular magnetic recording (PMR) was developed to surpass the super-paramagnetic limit of longitudinal disks for even higher recording density [1], and the stress induced demagnetizations are even more critical [2]. Therefore, the scratch resistance of PMR disks is an important issue. We analyzed the scratch performance of a trial PMR disk by focusing on scratch induced demagnetization.

2. Scratch Test

The scratch resistance of a disk can be evaluated at a drive level, e.g., an operation shock test [3]. However, a drive level test needs a magnetically capable head and disk and is usually time consuming. We instead proposed a component level scratch test method. The first, the disks whose magnetic pattern was randomly pre-written are used. Then, scratch mark was scribed using a stylus type scratch tester. The stylus was spherical, and had a $0.5\ \mu\text{m}$ tip radius and 100-400 μN applied load. The scribing velocity was as slow as 0.1 mm/s to avoid any friction heating effects on the demagnetization [4]. The scratch depth was measured by an atomic force microscope (AFM) and the demagnetization was analyzed by a magnetic force microscope (MFM).

3. Results

The AFM and MFM images of the scratched areas at applied loads of 100 and 200 μN are shown in Fig. 1. The scratch was scribed in a circumferential direction on the disk, i.e., across the bit length direction. When the applied load was 100 μN , the scratch depth was about 1.1 nm, and no demagnetization was observed in the MFM image. However, when the applied load was increased to 200 μN , the scratch depth increased to about 3.8 nm, and demagnetization was observed in the scratched area.

A scratch scribed in a radial direction on the disk, i.e., along the bit length direction, was also investigated. A comparison with the circumferential direction, both the depth of the scratch and demagnetization showed similar behaviors. We conclude that the demagnetization is not related to bit orientation.

4. TEM Analyses and Discussion

For understanding scratch induced demagnetization, we conducted a cross-sectional analysis of the scratches by using transmission electron microscopy (TEM).

The TEM image of the scratched area of the trial PMR disk is shown in Fig. 2. The demagnetization observed disk was used. The carbon overcoat of the disk remains. It was not damaged by the scratch, but the grains in the recording layer tilted significantly, up to about 30° . From this observation, we believe that scratch induced demagnetization is closely related to the grain tilt of the recording layer. A simple schematic calculation (Fig. 3) shows that a grain tilt of 30° contributes about 2 nm to scratch depth. Therefore, dense and not easily tilted grains in the recording layer are important for scratch resistant PMR disks.

5. Conclusion

Scratch tests and a study of scratch induced demagnetization were conducted for a trial PMR disk. Scratch induced demagnetization happens when the scratch depth is up to 3.8 nm. After analyzing the structure of magnetic layer in disk with TEM, it was found that the grain of the recording layer,

which is vertically orientated in a PMR disk, tilted under the scratch. A recording layer with a dense and not easily tilted grain structure is a must for a reliable hard disk drive.

INTRODUCTION

As areal densities approach the Tb/in² point, the requirement for ever lower head-medium spacing (HMS) is increasingly urgent. Conventionally, HMS has included fly-height, head and disk overcoat and head recession. More recently, it was deemed convenient to divide fly height into the sum of the disk touch-down height (TDH) and the head-disk clearance. Moreover, disk lubricant thickness, which had long been a negligible part of the HMS budget, cannot be ignored any longer [1], and it now amounts for about 10% of the total HMS. In addition to the static aspect of the lubricant contribution to spacing, dynamic aspects (i.e. moguls, ripples) stemming from slider interactions have to be taken into account as well [2]. Finally, some recent modeling work has been published that describes the evolution of a lubricant film on a slider surface. Such phenomenon is highly relevant to today's head-disk interface, as lubricant pickup from the disk to the slider is known to affect overall drive reliability.

In this paper, we will describe experiments and modeling aimed at better understanding lubricant dynamics on a slider air-bearing surface (ABS), both at rest and during flying. We will present recording data obtained on intentionally lubricated sliders, that suggest a slow removal of lubricant off the trailing ABS pad by air shear. An attempt will be made to reproduce experimental data with modeling calculations, using shear maps obtained from an air-bearing solver.

EXPERIMENTAL

Heads and Disks: Femto-long heads, designed to fly at a nominal 9nm at 15,000RPM, were lubricated with 2nm of fractionated ZTetraol (Mn=3010) using standard dipping procedures. Lube thickness was estimated from TOF-SIMS imaging. Sliders were flown on a standard commercial disk.

Recording Measurements: Immediately after loading the head, a servo pattern and a square wave bit pattern at 700 MFlux/s were written. The servo pattern ensured that the head stayed on track, thereby eliminating effects of thermal drift and minimizing the noise in the read-back signal. After applying a correction for thermal decay, the Wallace spacing loss formula was used to estimate the change in head-media spacing from the readback amplitude.

Modeling: Shear maps were calculated using the CML solver. Both Couette and Poiseuille shear maps were computed at the ABS surface, and added together. Shear flow was calculated assuming a no-slip boundary condition, using bulk viscosity values. Flow from diffusion was obtained using a constant diffusion coefficient obtained experimentally. We used a “free” lubricant layer of 1nm thickness with an effective viscosity equal to twice the bulk viscosity, on top of a “restricted” layer of 1nm thickness [4].

RESULTS AND DISCUSSION

Figure 1 shows lubricant maps obtained at various times. It is clear that the lubricant is generally being displaced downtrack from the pads towards the deposited end (DE). These maps also delineate areas of stagnation where lubricant accumulates. These specific ABS locations are typically where droplets are seen when present. Another important feature is the fact the lubricant flow seems to avoid the ABS trailing pad. This beneficial feature originates from the fact that the down-track component of the shear stress is negative around this area, in effect pushing the lubricant away from it.

Figure 2 shows experimental magnetic spacing evolution from two different heads, as a function of time. As the lubricant film is displaced from the trailing pad, spacing decreases slowly by a total of 0.4-0.8nm in about 2 hours of continuous flying. This curves compare favorably with the model prediction, obtained by calculating the average lubricant film change on the trailing ABS pad as a function of time.

In the full paper, more experimental and modeling details will be described. In particular, the effect of viscosity will be probed by showing results obtained on sliders coated with Zdol. Also, the effect of diffusion constant of the lubricant on the etch cavity will be investigated.

Effect of Thermal Bonding on Frictional Properties of Monolayer Lubricant Films Coated on Magnetic Disk Surfaces.

H. Zhang¹, Y. Mitsuya², A. Fuwa¹, Y. Fujikawa¹, K. Fukuzawa¹

1. Nagoya University, Nagoya, Japan; 2. Nagoya Industrial Science Research Institute, Nagoya, Japan

Monolayer perfluoropolyether (PFPE) films that are partially bonded to the disk surfaces are widely used for lubrication of magnetic disks. The bonding ratio (ratio of bonded thickness to total film thickness) may impact tribological behavior of lubricant films; however, studies so far are limited to conditions of heavy load and fast rotation that possibly damage bonded molecules. In this work, under lightly loaded and slowly rotated conditions, we measured the frictional properties of monolayer PFPE films that had different bonding ratios adjusted by thermal treatment. Friction mechanisms of mobile and bonded molecules are discussed by comparing the sliding-speed-dependent and molecular-weight-dependent friction properties.

Magnetic disks overcoated with 3-nm-thick amorphous-nitrogenated carbon films (average surface roughness: 0.45 nm) were used. The lubricants used were PFPE Zdol2000 and Zdol4000, functional polymers with different molecular weights of 2000 and 4000 g/mol, respectively. PFPEs films were dip-coated on the disk surfaces and were then annealed at 120°C. Anneal time was varied to adjust the bonding ratio. The total film thickness after thermal treatment was fixed at 2 nm. A self-developed pin-on-disk type tribotester [1] was used for friction measurements. A glass ball with a 1.5-mm diameter and an average surface roughness of 0.6 nm was used as the slider. The slider was loaded at a radius of 20 mm and the rotational speed of disks was set at 1 or 2 rpm. The external load from 0 to 1 mN was incrementally applied after one sliding revolution. At each external load, friction forces were measured at 60000 points during sliding and their average was taken. Figure 1 shows the frictional properties of Zdol2000 films with different bonding ratios measured at 1 rpm. Friction of the 5%-bonded (non-annealed) film increased linearly with external load as described by Amontons' law. In contrast, friction forces of the annealed films increased with increasing bonding ratio and exhibited a nonlinear load dependency, which were well fitted by the Johnson-Kendall-Roberts model as plotted with solid curves in Fig. 1. Figure 2 compares the frictional properties measured at 1 and 2 rpm for the 5%-bonded and the 100%-bonded Zdol2000 films. With increasing speed, friction of the 5%-bonded film increased, whereas friction of the 100%-bonded film showed no obvious change. We thus speculate that mobile lubricant molecules show liquid-like frictional properties which are dominated by viscosity resistance, whereas bonded lubricant molecules exhibit elastomer-like frictional properties which are determined by energy dissipation during molecule deformation.

Figure 3 shows the frictional properties of Zdol4000 films measured at 1 rpm. Properties similar to Zdol2000 were observed. In contrast to Zdol2000, however, the dependency of friction on bonding ratio was weaker for Zdol4000. Compared with Zdol2000, Zdol4000 has a larger molecular weight, and thereby a higher viscosity and a longer chain length (equivalent to a higher flexibility of bonded molecules). Considering the liquid-like and elastomer-like properties of mobile and bonded molecules, these differences can rationally explain the larger friction of non-annealed Zdol4000 films and the lower friction of bonded Zdol4000 films as compared with Zdol2000.

To ensure the reliability and durability of the head disk interface of magnetic disk drives, the lubricant film flow on the disk surface has become a significant concern since it is related to recovery performance when the film is damaged. So far, the flow characteristics of lubricant film have mainly been evaluated using the flow from the step-shaped lubricant boundary (step-boundary flow). This flow is categorized to that under ideal conditions, which is quite different from the sliding-induced depletion of lubricant film. In the present study, step-boundary and replenishment flows were compared for perfluoropolyether (PFPE) lubricant to clarify the similarities and differences between the two conditions.

2.5 inch-sized magnetic disks covered with hydrogenated diamond-like carbon and coated with Zdol2000, a polar lubricant, were used for flow measurements. The step-boundary and replenishment flows were measured through film profile changes with elapsed time using a scanning ellipsometer and an optical surface analyzer.

To measure the replenishment flow, lubricant depletion was made by in-contact sliding of a glass ball with a diameter of 1.5 mm. Gentle and mild sliding conditions were selected to avoid severe damage to the layering structure of the lubricant molecules. The conditions include a sliding velocity of 0.52 m/s, a loading force of 20 mN (2 gf), and disk turns of 30,000 passes. To accelerate depletion, the glass ball was driven oscillatorily in the disk radial direction at a frequency of 0.5 Hz and a seek distance of 0.2 mm. Typical lubricant profile changes for the two cases thinner than the monolayer (coated film thickness: $h_0=2.0$ nm) and nearly bilayer ($h_0=4.6$ nm) are demonstrated in Fig. 1 with elapsed time as a parameter. The monolayer case exhibits an ordinary recovery process, while the nearly-bilayer case exhibits a peculiar feature in three categories: i) a typical U-shaped valley appears as if the lubricant was peeling off; ii) reflow profiles from the peak toward the original lubricant surface and toward the valley are quite different; iii) the left bank of the valley moves forward, which means that the piled up molecules are flowing to the valley, while the right bank remains stationary, as if the lubricant molecules are frozen. The behavior of the right bank suggests that an unrecoverable phenomenon might occur under special conditions.

Depletion recovery rates for different initial coated film thicknesses are compared in Fig. 2, where the rate is defined as the area of the recovery cross section divided by the initial depleted cross section. The recovery rates for the monolayer and multiplayer cases are found to be roughly proportional to a logarithmic scale of time. However, for the nearly-bilayer case, the recovery rate exhibits saturation from the early stage.

The step-boundary flow was measured using the same lubricant/disk combinations as in the replenishment flow. Comparing these two flows, the unrecoverable phenomenon occurred when the bottom thickness of the valley, h_b , reached the monolayer thickness [1]. Using the spreading profiles, the diffusion coefficient distribution was calculated (Fig. 3). The diffusion coefficient, which became maximum around a thickness slightly thinner than the monolayer thickness, sharply decreased with thickness, which corresponds well to the recovery rate shown in Fig. 2. The unrecoverable phenomenon cannot be explained from the diffusion coefficient distribution obtained from the step-boundary flow, but it can be attributed to the unstable phenomenon peculiar to polar lubricants.

Coverage Analysis of Molecularly Thin Lubricant Films using Molecular Dynamics Simulations and CAICISS Measurements.

Y. Ikai, N. Nakamura, H. Chiba, T. Imamura
Fujitsu Laboratories Ltd., Atsugi 243-0197, Japan

Introduction

In recent HDD products, the flying height of head sliders has been reduced to less than 10 nm. For further reduction of the flying height, a lubricant film on a disk surface has to be thinned with maintaining the complete coverage over the surface. It was difficult, however, to precisely investigate the molecular-scale conformation of the lubricant films using conventional techniques.

A new method using coaxial impact collision ion scattering spectroscopy (CAICISS) was proposed to evaluate the coverage of thin lubricant films [1]. CAICISS can quantify chemical compositions on a surface by detecting the energy of the helium ions backscattered on the surface. In the proposed method, it was presumed that if a lubricant film of perfluoropolyether completely covers the surface, the fluorine-to-carbon atomic ratio (F/C ratio) of the surface should become 2.

In this study, we calculated the conformation of molecularly thin lubricant films by molecular dynamics (MD) method, and investigated the validity of the coverage measurement method using CAICISS.

Simulations

Tanaka et al. [2] calculated coverage properties of Fomblin Z DOL on a disk surface by MD simulations. We carried out similar calculations to generate lubricant films of Fomblin Z TETRAOL 2500. The lubricant molecules were placed one after another at 6.0 nm height above the surface with an initial velocity toward the surface. Using this method, we generated four different lubricant films with randomly varying the initial position of each molecule. The generated films were separated into two groups in regard to the conformation. Figure 1 (a) is one of the high coverage results and Fig. 1 (b), the low coverage ones.

We then calculated the coverage and F/C ratio as a function of the film thickness. The coverage was simply calculated as a ratio of the covered area to the entire analysis area.

The F/C ratio was calculated assuming the CAICISS measurements. As Fig. 2 shows, we counted the numbers of F and C atoms considering the shadow cone radii [3] at an incident angle of 15 degrees from the surface. Figure 3 shows the calculated results for the high coverage group (a) and low coverage group (b). For both cases, the F/C ratio gives good agreement with the coverage at any film thickness. It shows that the coverage measurement method using CAICISS can evaluate the accurate coverage of lubricant films even with molecular-scale holes.

Experimental

We measured the F/C ratio of the samples prepared for different film thickness using CAICISS. The measurement parameters here were He for the incident ions, an acceleration voltage of 2 keV, and an incidence angle of 15 degrees from the surface.

Figure 4 shows the F/C ratio measured by CAICISS in comparison with the four calculated results. The high coverage results of the simulations gave good agreement with the measurements, and the low coverage ones were significantly lower than the measurements. It means that the high coverage group better expresses the conformation of the prepared sample.

Conclusions

We carried out MD simulations to generate lubricant films on a carbon protective film and calculated the coverage and F/C ratio for various film thicknesses considering the shadow cone radii. From the simulation results, we confirmed that the coverage measurement method using CAICISS

can evaluate the accurate coverage of molecularly thin lubricant films. We also verified the MD simulation results in comparison with the CAICISS measurements.

Time Dependence of Head-Media Interference at Low Fly Heights.

J. He, J. Hopkins, S. Duan, K. Johnson
HGST, San Jose, CA

Touchdown height (TDH) is the fly height (FH) at which the head and disk start to make sustained contact. In the past, TDH had been found to correlate with disk roughness [1, 2]. However, the picture becomes significantly more complicated with the use of ultra smooth disks. Low roughness surfaces allow the head to fly much closer to the disk allowing forces that used to be negligible to come into play [3, 4, 5]. Lubricant film on the disk adds additional complication. The mobility of the lube allows the formation of lube moguls and/or ripples under the flying head that lead to head disk interference [6, 7]. All these effects make the head disk contact much more complicated than the simple picture of asperity or roughness induced contact.

In this paper, we describe a phenomenon that when a head is flying on a lubricated disk at FH values near the TDH, the onset of head-disk interference is a function of the FH and the flying time. The time to interference is called the Contact Free Time (CFT). We propose a lubricant migration mechanism to quantify CFT. A calculation based on this hypothesis agrees reasonably well with the data. Fig. 1 shows the plot of the quartic root of the CFT vs. FH and the result is seen to be extremely linear. The finite time needed for head-disk contact to develop reveals the subtle yet critical role of the lubricant. Lubricant dynamics under the influence of a flying head have been studied by others. One particular experiment shows that lube moguls form at the peaks of the substrate topography [6]. This result was not expected since the lube would be naturally pushed down from the top of peaks due to strong air shear. Nonetheless, the authors were able to make a convincing argument that lubricant flow would migrate to the peaks based on the disjoining pressure gradient originating from van der Waals forces. In this study, the head was flying on the order of 15 nm, much higher than the ~2.5 nm FH in our experiment. Because the van der Waals forces increase inversely with the cube of the head media separation, the disjoining pressure gradient should be an even greater effect for our work.

The mechanism of the formation and growth of lube moguls is illustrated in Fig. 2. Moguls grow in height with each pass of the slider until one or more of the lube moguls bridges the head and disk. The capillary force of a lube-bridged head-disk system is on the order of 5 mg-force for a 10 μm x 10 μm lube filled area [8]. This force is large enough to cause the head to hit the disk surface. We calculate lube flow from only the effect of the disjoining pressure gradient (Poiseuille flow) following the formulism and lubricant parameters from [5] and [8].

The flow of lubricant due to disjoining pressure gradient is:

$$q = h^3 / 3\eta \partial\Pi/\partial x, \quad (1)$$

where h is the lubricant film thickness with an average thickness $h_0 \sim 1\text{nm}$, η is the effective viscosity $\sim 1.0\text{ Pa}\cdot\text{sec}$, and Π is the disjoining pressure. The continuity equation is:

$$\partial h/\partial t = -\partial q/\partial x \quad (2)$$

The change of disjoining pressure due to the head is:

$$\Delta\Pi = -A / 6\Pi (FH - h_0)^3, \quad (3)$$

where A , the Hamaker constant, $\sim 10\text{-}19\text{ J}$

Combining the above equations, we derive the CFT as:

$$\text{CFT} = c_4 (FH - h_0)^4, \quad (4)$$

where $c_4 = (9\Pi \eta \delta a^2 \lambda / 2A h_0^3 \Delta t)^{1/4}$

δa is the length parameter characterizing the sharpness of the slider trailing pad edges (where the disjoining pressure gradient arises) and is taken to be $1\mu\text{m}$. Δt is the interaction time between the

lube and the head can be expressed as the duty cycle, $\sim 10\text{-}4 \lambda$ where λ the period of the rotation [6].

From eqn. (4), c is the slope of $t^{1/4}$ vs $(FH - h)$, $\sim 6.1 (s^{1/4}/\text{nm})$, quite close to the value of 8.3 in Fig. 1. c is proportional to $\eta^{1/4}$ and inversely proportional to $h_0^{3/4}$, and is amenable to verification with different lubricant types and thicknesses. We can also draw a conclusion from the expression that the head will be able to fly stably longer on disks with thinner and higher viscosity lubricants.

Air bearing surface designs for less humidity sensitivity.

S. Zhang, G. Tyndall, M. Suk

Advanced Technology, Samsung Infomation Systems America, San Jose, CA

I. Introduction

In today's hard disk drives, air passing under the slider is typically compressed more than 10 times the ambient pressure. If the drives are running in a humid environment, the water vapor contained in the air can be easily compressed to reach super-saturation in the air bearing, which may cause the condensation of the vapor and thus the pressure drop in the air bearing. As a result, the air bearing is unable to support the slider with the existing flying attitude and needs to lower slider's flying height (FH) to regain the air bearing forces to balance the forces from the suspension [1, 2]. To minimize this humidity effect, one efficient method is to optimize the air bearing surface (ABS) to get it less sensitive to the humidity. In this paper, we present the concept of the air bearing's humidity sensitivity and strategies about how to reduce it through ABS optimization. Three ABS designs are proposed to illustrate the optimization approach. The simulation results indicate that the humidity sensitivity can be reduced significantly for optimized ABS than that not optimized.

II. ABS Designs for Less Humidity Sensitivity

Slider loss its FH in a humid environment and the amount of FH loss is related to both the relative humidity (RH) and temperature, the two parameters that determine the water content in the air bearing [1, 2]. We define the humidity sensitivity of an ABS as a ratio of FH at RH 70% and temperature 70 C divided by the FH under dry condition. The higher the ratio, the less sensitive of the air bearing to the humidity is.

The sensitivity ratio can be calculated by solving the FH under humid and dry conditions numerically. In brief, we solve the Reynolds equation for the FH under dry condition using the CML code [3] directly, and solve a humidity model that combines a solution of Reynolds equation with a pressure adjustment for the FH under a humid condition [2].

In order to reduce the humidity sensitivity, we have two methods in terms of ABS design: one is to optimize ABS to yield a smaller loss of air bearing force induced by vapor condensation. A derived equation indicates that a lower air bearing pressure can help to realize it [2]. But it is conditionally effective because when the pressure is lowered somewhere in the air bearing, it has to be increased somewhere else to maintain a constant air bearing force to balance the force from suspension unless a smaller suction force is preferred that may trade off air bearing's stiffness. Another method for reducing the humidity sensitivity is to optimize ABS to have a stiffer air bearing to resist the FH loss due to the vapor condensation. The air bearing stiffness is defined as the change of the air bearing force under a unit change of the slider's flying attitude such as FH, pitch or roll angles. A stiffer air bearing needs a smaller FH adjustment to compensate a given amount of change of air bearing force.

Based on the above discussion, we propose three ABS designs (Fig. 1) that have different humidity sensitivity. They are for 3.5" drives and fly at the same FH with a rotation speed 7200 rpm. Table 1 shows the simulation results of humidity sensitivity and air bearing stiffness for the three ABSs. The results indicate that Design 1 is the most sensitive to the humidity while Design 3 is the least. If look at the peak air bearing pressure, it does not show a direct relation with the humidity sensitivity explicitly because the loss of air bearing forces is not just a function of the peak pressure, but also a function of the pressure distribution over the whole integration area. The results in Table 1 also show that the air bearing stiffness has a major contribution in minimizing air bearing's humidity sensitivity. The higher the air bearing stiffness, the less humidity sensitive the air bearing is.

Because design 3 has the stiffest air bearing, it therefore gets the least humidity sensitivity among the three ABS.

III. Conclusion

ABS optimization is an efficient method to minimize the humidity sensitivity of the air bearing. To illustrate the optimization strategy proposed, we design three ABS with different humidity sensitivity. The simulation results indicate that the humidity sensitivity can be reduced significantly for optimized ones than those not optimized.

INTRODUCTION

Deposition of thick, high performance, permanent magnet(PM) materials is a critical enabling technique for the development of advanced magnetic microsystems. Recent approaches to fabricate thick PM films include sputtering of rare earth-transition metals or alternatively, electroplating of L10 CoPt or FePt alloys. However, both of these methods require high deposition temperatures and/or post-deposition annealing to achieve strong magnetization, which limits their compatibility within MEMS process flows. Co-rich CoPt films exhibit good magnetic properties in their as-deposited state due to the high anisotropy induced by the incorporation of Pt in the hexagonal phase of Co. Recently, Zana and Zangari electroplated Co₈₀Pt₂₀ thin films on textured seed layer of Cu (111) and Ru (0001) so that columnar growth and fine-grained microstructure were achieved [1, 2]. However, the previously reported films/arrays were limited to 2 μm in thickness. For MEMS device design, a large magnet volume is desired to achieve large magnetic forces and electromechanical energy exchange, so thicker films and patterned arrays are needed. In this work, Co-rich CoPt films/arrays with thickness around 10 μm are electroplated on both amorphous Cu and textured Cu(111) seed layers on silicon wafers.

EXPERIMENTS

Cu seed layers of 100 nm thickness were DC sputtered on silicon wafers by magnetron sputtering system without intentional heating [3]. Amorphous Cu seed layers formed on Si(100) wafers for which the native oxide had not been removed. In contrast, Cu (111) textured seed layers formed on H-terminated Si(110) wafers. After the seed layer preparation, AZ-4620 photoresist mask patterns with arrays of small magnets (150 μm x 150 μm) were defined by photolithographic techniques. Then, the CoPt was electroplated into the defined mask patterns from an amino-citrate bath [1]. The optimum electroplating conditions were found to be sensitive to the type of seed layers. Therefore, different sets of parameters were used for the two different seed layers [4]. The magnetic properties were measured by a VSM. In the analysis of the measured results, no demagnetization correction was performed.

RESULTS

After 90 min of electroplating, films with thickness of 8 and 10 μm were successfully fabricated on un-textured Cu and textured Cu (111) seed layers, respectively. The cross-sections clearly show that both films grew columnarly, as shown in figure 1. Figure 2 shows in-plane and out-of-plane hysteresis loops of magnetic films and arrays electroplated on un-textured and textured Cu seed layers. It can be seen that the coercivities reach as high as 260 kA/m (3300 Oe) and 330 kA/m (4100 Oe), respectively. The magnets on un-textured seed layers show perpendicular magnetic anisotropy with out-of-plane coercivity 260 kA/m much higher than in-plane coercivity of 130 kA/m. It is interesting to see that the magnets grown on textured seed layers did not show an out-of-plane anisotropy as reported in the previous investigations of thinner films [1, 2]. Instead, the magnets showed high coercivities of 330 kA/m and 320 kA/m for the out-of-plane and in-plane directions, respectively. In addition, in both cases, the patterned magnets arrays showed better squareness than that of films, due to the decrease of demagnetized field in the patterned arrays. The magnetic properties of the magnetic arrays are listed in table 1.

The in-situ measurements of magnetic properties, as magnetic susceptibility and gradient, are sometimes difficult tasks as there are no hand-held commercial devices. This kind of measurements are very important in mining and Magnetic Geology research both on Earth and in Space. At the Spanish National Institute of Aerospace Technology (INTA) it has been developed a magnetic susceptometer and gradiometer for measuring the magnetic properties of the Martian and Moon soil. As the magnetic signal is extremely low, a huge effort needs to be done to increase the Signal-to-Noise Ratio of the instrument. Thus, mechanical detection of the signal has been disregarded. Instead of it, we have developed an optical detection device based on optical fiber sensing techniques. In this work we report an optoelectronic device for the measurement of a vibrating magnetic Micro-Electro-Mechanical System (MEMS).

The scheme of the device (Figure 1) is very similar to [1, 2]. The light coming from a Light Emitting Diode (LED) is guided with a PolyMethyl-MethAcrylate (PMMA) optical fiber to a mirror on the vibrating MEMS. This light is reflected to the sensing fibers located around the emitting fiber ('Daisy' configuration). The light is then guided to a photodiode which will detect more or less light intensity depending on the distance of the mirror to the fiber extreme.

Figure 2 shows the voltage measured by the photodiode as a function of the distance by means of an EG&G photocurrent amplifier. In the figure it can be seen that the best sensing zone corresponds to the distances between 400 and 700 μm , the steepest part of the curve. The central part of this area is taken as the working point (WP) for further measurements.

Once the sensor is set in the WP we measure the sinusoidal variations of the voltage corresponding to the vibration of the magnetic MEMS. The amplitude of the signal produced by the vibrations of the MEMS is very small compared to that of the WP so to maximize the resolution of the device, a high pass filter (HPF) has to be added in the front-end electronics. In Figure 3 it is shown the schematic of the transimpedance amplifier and the HPF (cut-off frequency of the order of 10 Hz) used. The output of this circuit is directed to a lock-in amplifier.

The calibration of the 'Daisy' configuration fiber-optic sensor for a vibrating MEMS can be made with a piezoelectric loudspeaker with a well known amplitude to voltage characteristic curve. Figure 4 shows the locked-in signal versus the vibration amplitude of the loudspeaker. Every point is the average of 100 measurements. The calibration of the device by least squares method gives a slope of $1.8059 \pm 0.0011 \text{ mV}/\mu\text{m}$. The standard deviation of every point was used to determine the uncertainty, which is of 4 nm in the 100-1000 nm range.

The need for portable power generating devices is increasing rapidly, which spurred the research in micro electric power generation. In this paper, we present a design of micro generator attached to a flywheel that is passively supported by a high-temperature superconductor (HTS) bearing. The generator is in the form of the axial flux machine, which is also used as a motor to spin up the flywheel. We fabricated the stator coils using MEMS techniques. In this paper, we derived a mathematical model of the axial flux machine and verified the model against finite element analysis and experiments.

Fig.1 illustrates the schematic diagram of the system. The system consists of an electroplated planar stator, flywheel, and HTS bearing. The flywheel levitates above HTS when HTS is cooled and takes torque from the planar stator which consists of an axial flux type brushless DC motor/generator. The planar stator is fabricated with 5-lines, 100 μ m-width, and 50 μ m-height using MEMS techniques, as shown in Fig. 2. Fig. 3 shows the picture of the HTS bearing and the flywheel.

For the convenience of the analysis of the axial flux machine, we cut the motoring permanent magnets through an imaginary line at $r=R$, and unroll the axial surface as shown Fig. 4. Assuming the uniform field distribution in the radial direction, we can use 2D magnetostatic analysis to determine the field distribution. If we consider only the field by the motoring permanent magnets, the field is described by a potential equation $\nabla^2\psi=\nabla\cdot\mathbf{M}$ (1) where \mathbf{M} is the magnetization vector representing the permanent magnets. The magnetization vector in eq.(1) is a periodic function for our case, and can be expressed as a Fourier series. If we consider only the first term of this Fourier series (space fundamental), eq.(1) can be solved analytically after applying appropriate boundary conditions. The axial field is obtained as $B_z=\mu_0 M_0 \sinh(qt_m) \exp(-q(t_m+g)) \sin(qx)$ (2). Using this field equation, we can derived the torque and back-emf equation as $T=1.5 n_c k_b F_0 R_{avg} I_0$ (3) and $E_a=F_0 R_{avg} \omega n_c k_b \sin \theta$ (4).

The analytical model is verified with a finite element analysis. The designed axial flux machine is built and tested in a prototype. The flywheel in the prototype rotates up to 51,000 rpm and stores the rotational kinetic energy of 337J. The complete spin down time is 3hr 20min inside a vacuum chamber. At maximum speed, the no-load three-phase electric output of the micro generator is 802mVrms, which matches with the model.

Introduction

Achieving the desired properties of magnetic thin-films is a precondition for a successful fabrication of magnetic micro devices. Typically, these films are anisotropic, with a hard and an easy axis perpendicular to each other. In this case, it is necessary to measure the properties of such films along both axes to guarantee that the specified magnetic properties are met. Such a non-destructive in-situ measurement using micro sensors substantially increases the production efficiency [1]. This paper presents the development and fabrication of a hysteresis measurement system consisting of two independent sensors oriented at an angle of 90° to each other. This allows measuring the properties of anisotropic magnetic thin-films along the two desired axes. Each sensor represents a micro transformer, with the magnetic thin-film forming one leg. The measurements of the magnetic properties have to be carried out at exactly the same location. To fulfill this requirement, the sensors are designed to alternatively being engaged at the measurement spot. The sensors are intended for mounting in a micro actuator ultimately, which will perform the positioning [2]. The Leibniz Universität Hannover's Institute for Microtechnology (imt) carried out design and fabrication of the hysteresis loop micro sensor, while the innomas developed the measurement electronics executed the sensor evaluation.

Design and Fabrication

To achieve an optimal micro sensor design, a Finite Elements Method (FEM) analysis was carried out using ANSYS simulation software [3]. The induced voltage in the sensing coils is proportional to the change of magnetic flux in the magnetic layer.

The hysteresis loop micro measurement system was fabricated in thin-film technology. Each micro sensor consists of a NiFe81/19 ring core with air gap and two pairs of spiral coils. The core's gap orientation determines the measurement direction. Therefore, the two gaps are perpendicular to each other and this way covering both the easy and the hard axis of the magnetic thin-film. The magnetic core has a footprint of 400 µm x 400 µm, the air gap length is 30 µm. The total building height of the micro sensors is 62 µm. Each core carries a pair of six-turn excitation coils on top of two ten-turn sensing coils. The cross sections of the coils are 10 µm x 12 µm and 5 µm x 5 µm, respectively.

The micro sensor system was deposited on a glass wafer in five layers. For fabricating both the core components and the coil layers, electroplating NiFe81/19 and Cu, respectively, were applied. Photo masks were used for patterning micro molds for the deposition. As insulation material, photosensitive epoxy (SU-8TM) was used [4]. Seed layers required for electroplating on insulators were created by sputter deposition and (in case of the coil seed layer) removed by Ion Beam Etching (IBE) after completing the electroplating process. The first and the last layer were planarized using Chemical-mechanical Polishing (CMP) [5, 6]. Figure 1 shows a micrograph of the fabricated hysteresis loop micro sensor chip.

Experimental Results

For an excitation sinus current of 31 mA, a frequency of 100 kHz, and a material film thickness of 20 nm, a measurement signal of about 6 mV was achieved. Comparing the results measuring with-

out probe a significant increase of the induced voltage is shown. The difference between the measurement wave form with and without probe allowed to reconstruct the hysteresis loop.

Magneto-Impedance (MI) sensor is very attractive as a highly sensitive magnetic field sensor. However, certain amount of bias field is required for operation because the sensor has only poor linearity and small sensitivity around zero magnetic field. To solve this problem, integration of SmCo thin film magnet with MI sensor has been proposed [1], where the magnet can generate only a fixed bias field. When we consider practical use, adjustability of the bias field after fabrication is desirable because dimensions and characteristics of the magnetic film can vary according to unintentional variations in fabrication conditions while precise setting of the bias field is essential to obtain high linearity as well as high sensitivity. In this paper, we propose an adjustment method of the bias field of a thin film magnet integrated with the MI sensor. We fabricated a CoNbZr thin film MI sensor with L-10 FePt thin film magnet, and showed that it is possible to adjust the bias field after fabrication.

Figure1 shows a top view of the fabricated sensor, where two Meander-type thin film MI sensors were arranged on FePt film side by side so that we can compose a Wheatstone bridge circuit by adding two resistors. Firstly, a 1.3 μ m thick FePt film was RF-magnetron sputter deposited on a Si substrate, was patterned into a 0.6 mm-long and 2.4 mm-wide square by lift-off process, and then was annealed at 600 degrees C. After forming a 1 μ m thick SiO₂ layer, a 1 μ m thick amorphous CoNbZr soft magnetic film was sputter deposited, then was patterned into 500 μ m-long and 30 μ m-wide meander lines by lift-off process. After forming Al electrodes, uniaxial anisotropy was induced in a transverse direction of the CoNbZr stripes by a rotational field annealing followed by a static field annealing of 3kOe at 400 degrees C. Finally we magnetized the FePt film with a static field of 10 kOe at RT.

We evaluated MI properties of the sample when various magnetizing angles were given in an in-plane direction with respect to the magnetizing field. Because the MI sensor has the sensitivity only along with its longitudinal direction, cosine components of the bias field generated by the magnet work as an effective bias field. In order to control the magnetization angle precisely, in-plane isotropy of the magnet film is required. The magnetization curve of the FePt film after the whole process that is shown in Fig.2 indicates good isotropy even after the field annealing of CoNbZr film.

Figure3 shows MI properties of the sample with magnetizing angles of 0-90 degrees. A bias field of 13.1 Oe was obtained when the magnetization is in the longitudinal direction, i.e., magnetizing angle is zero. We confirmed that the effective bias fields that can be estimated from the field shift in the Fig.3 coincide well with the cosine component of the bias field at zero degree as shown in the inset. We composed a Wheatstone bridge circuit and measured the bridge voltage induced by a pulse voltage as a function of externally applied field, which is shown in Fig.4. A linear sensor property was obtained.

In summary, we proposed the adjustment method of the effective bias field based on the magnetization-angle control of FePt bias magnet and achieved linear sensor characteristics in the fabricated sample.

INTRODUCTION

We have presented a pulse frequency modulation (PFM) amorphous wire CMOS IC Magneto-Impedance (MI) sensor¹, which enable to omit the analog-to-digital (A/D) converter in the electronic compass for mobile phone application² by counting the number of the microprocessor timing pulse in the multi-vibrator pulse width. Elimination of A/D converters is useful for downsizing, speed up and cost cutting in the mobile phone electronic compass. However, output stability of the PFM-MI sensor should be improved by canceling the fluctuation of sensor circuit parameter (R, C) with temperature variation.

We newly constructed a pulse width modulation (PWM) amorphous wire CMOS IC MI sensor on the basis of the PFM-MI sensor detecting the pulse duty ratio proportional to the applied magnetic field strength, in which the sensor circuit parameter (R, C) are canceled in the sensor output equation for improvement of the magnetic field sensing stability for temperature variation.

PWM-MI SENSOR CIRCUIT

Fig.1 represents a PWM-MI sensor circuit configuration modifying the PFM type amorphous wire CMOS IC MI sensor.

Capacitor C1 begins to charge through resistor R1 toward Vdd. When the voltage across C1 reaches the threshold voltage Vth, the output of inverter Q1 goes LOW and that of Q2 goes HIGH, turning analog switch S1 ON and thereby discharging C1. The current from C1 is drawn the ground through r, an on-resistance of analog-switch. Two charge-discharge operations continue indefinitely, and the period of oscillation is therefore $T = T_1 + T_2$ (see Fig.2).

T is approximately to be the charging periods of T1charge and T2charge.

The sensor output is the pulse duty ratio expressed in equation (1) (see Fig.2), in which the sensor circuit parameter (R, C) is canceled, while R,C appear in the sensor output (pulse frequency) of the PFM-MI sensor expressed as $f = 1 / F(RC) 1$.

Fig.2 shows dc magnetic field detection characteristics of the PWM-MI sensor.

A non-hysteresis detection characteristic is obtained for ± 1 Oe, which is transformed to a highly linear characteristic in the microprocessor signal processing.

Fig.3 shows measured results of the output stability of the PWM-MI sensor for temperature variation (25 – 65 degrees centigrade). A highly stable characteristic is resulted in the PWM-MI sensor with the output variation less than about 0.1%/Celsius, while the output variation is large in the PFM-MI sensor of about 3 %/Celsius.

Microfabrication process and characteristics of thin-film noise suppressor integrated onto the re-wiring layer of a LSI chip.

M. Yamaguchi¹, T. Fukushima¹, T. Akiba², A. Nakamura²

1. Dept. of Electrical and Communication Engineering, Tohoku University, Sendai, Japan; 2. Division of Process & Device Analysis Engineering Development, Renesas Technology Corp., Kodaira, Japan

Ferromagnetic resonance (FMR) losses of soft magnetic thin film are useful for suppressing electromagnetic noise up to GHz range generated from a Large Scale Integration (LSI) chip. Basic researches for model transmission lines [1], [2] and preliminary demonstration for package-open LSI chip [3] are reported already. In this paper we proceeded to find out a practical need for magnetic film integration for a LSI chip, processed the film on the bare LSI chip, also processed hundreds of solder bumps for flip-chop bonding, and actually evaluated the magnetic near field emission.

The targeting application is for a re-wiring layer on a LSI chip. The re-wiring layer offers ever thick and long multilayer wiring which meet a need to increase the number of wires on a LSI chip having a fine design rule [4]. Typical thickness of the wire is more than a few microns and length is longer than a millimetre. These wires are processed at the final step of microfabrication process and the use of re-wiring layer is growing year by year. On the other hand, the power carrying and the information carrying electric currents flowing in the densely drawn re-wires often cause electromagnetic noise problem.

The test chip is a one-chip microprocessor with size of 10.8 x 10.4 mm² and chip thickness of 725 μm . The clock frequency is 40 MHz and the corresponding frequency spectrum reaches several hundred MHz and beyond. The close-up view of the chop is shown in Fig. 1. There are nominally 300 solder bump electrodes with diameter of 250-300 μm . A 1.0 μm -thick Co₈₅Nb₁₂Zr₃ amorphous soft magnetic film with saturation magnetization of 1.1 T, anisotropy field of 845 A/m, relative permeability of 1000 and ferromagnetic resonance frequency of 1.1 GHz was sputter-deposited on top of the polyimide passivation layer, followed by 0.5 μm -thick SiO₂ deposition to make sure the insulation. After electrode opening by a lift-off process, the chip was annealed at 340 degree-C for 2 hours in a dc 0.3T field. Then solder bumps were formed by a screen-mask method. We also processed copper film instead of magnetic film as a reference. The completed chip is shown in Fig. 2 and was then bonded to a test printed circuit board to evaluate magnetic near field emission.

An electromagnetic near field measurement system (Type EMV-200, Hitachi display device, Inc.) with the probe size of 2.2 mm² was used at a measurement distance of 3.85 mm in a frequency range of 10 MHz-1.44 GHz. The level of magnetic filed was successfully attenuated by the magnetic film, which was better than Cu film up to 360 MHz (9th harmonic). Attenuation of 3-7 dB was also seen up to GHz range. Maximum attenuation achieved was 6.7 dB at 774 MHz. These demonstrate the usefulness of magnetic film.

1. Functional Materials Research Center, Korea Institute of Science and Technology, Seoul, South Korea; 2. Material Science & Engineering, Yonsei University, Seoul, South Korea

Magneto impedance (MI) effect, which implies sensitive change of impedance of soft magnetic materials with external magnetic field, has been attracted experimental and theoretical investigations because of its high sensitivity, resolution, and low power consumption. [1~3] In particular, the fact that the sensitivity of MI device is one of the highest of all magnetic sensors intrigued efforts to develop small field detection sensors such as magnetic particle detector.

However, conventional MI devices having millimeter dimension, despite their high MI ratio, cannot exploit the full capacity of MI effect because field measurement often involves spatially localized one. Moreover, since the MI effect is closely related to the magnetic permeability of the soft magnetic materials, impedance response to the external magnetic field shows basically non-linear and symmetric behavior which can be problematic for practical application. [4] In this work, we have fabricated calibrated MI sensors with micro dimensions using $\text{Co}_{32}\text{Fe}_{32}\text{Ni}_{34}$ electroplated nanocrystalline wires which is expected to be adequate for localized magnetic field detection.

CoFeNi soft magnetic alloys with width: 30~70 μm , length: 40~150 μm , and thickness: 1 μm were electroplated on silicon substrates. For electrical contacts, outer (inner) electrodes with 75 μm (40 μm) in length were deposited on the wires by sputtering method. For ac measurement, we used a function generator as a signal source while the rms value of the device ac voltage was converted into dc value using Analog Devices AD8361 rf detector chip and then amplified in order to increase signal to noise ratio. This measurement technique is adequate for small ac signal measurement of which typical amplitude is less than a few hundreds of micro volts.

Figure 1. shows the MI profile of micro sized sensor. The maximum value of MI ratio of our devices with respect to external magnetic field was measured to be 22% as the ac current with the frequency of 22MHz and the power of 5dBm was applied. In order to obtain linear response, the device output was calibrated in the external field range of 0~10 Oe by numerically fitting sensor output to sigmoidal function and calculate inverse value from stored numerical coefficient. Figure 2. illustrates final output characteristic of the device. From linear fit, it was shown that the slope of the calibrated output is 1.00326 and has linearity of 0.7%FS. Furthermore, sensitivity of sensor output was found to be 4.1mV/Oe. Considering voltage detecting capability of conventional digital voltmeters, this result shows that the present device can detect magnetic field having magnitude less than 0.05Oe and spatial localization, in average, a few micro meters.

In summary, we have demonstrated that magneto impedance sensor can be miniaturized with retaining its macroscopic sensitivity. Although further work needs to be done in order to realize in-situ and dynamic detection of magnetic particle, it is expected that the calibrated sensor of this kind can be applied to the localized magnetic field detection such as chip-cytometer.

1. Background

Recently GMI sensors based on amorphous magnetic metal wire has been commercialized and is expanding its application fields. Major commercial applications include motion sensors for mobile phones and electronic compasses for automobile.

Although GMI sensor has potentiality to offer very high sensitivity of about 0.1nT resolution¹⁾, commercialized products shows relatively low sensitivity, with the noise level of +/- 300-500nT. It is rather due to the cost/performance consideration for the nature of applications, which measures mainly geomagnetism. The authors tried to improve the sensitivity and attain lower noise level in order to expand the application field of the MI sensors.

2. Development

Low noise level of nano-tesla order was made possible by following 2 developments.

(1) Sensor element design

Special design is applied to achieve high sensitivity. Fig. 1 shows the magnified view of the element. Sensor coil is wrapped around the amorphous wire with the pitch of 50 microns with MEMS technology. The length of the wire is set to 4 mm, in order to reduce the demagnetizing field.

(2) Low noise electronic circuit (Fig. 2)

AC coupling is applied so that only the changing magnetic field can be effectively detected, and high resolution amplifier is selected. These measures create very high sensitivity with low noise level.

3. Results

Noise of the sensor output were observed in a magnetic shield tube. Fig. 3 shows the comparison of outputs between electronic compass product and developed sensor. Noise level were suppressed in +/- 0.5 nT. A photograph of the developed sensor is shown in Fig. 4.

4. Applications

Developed high sensitivity sensor enables new applications. One example is food inspection. This sensor was confirmed to detect an ferrous object as small as 0.3mm diameter in food. Second example is traffic counter. The sensor was able to detect minute magnetism that generated from an automobile even from the road side. From the detected signal, we can obtain passing car numbers, car speeds, and car lengths are calculated. Many other useful applications are expected.

3-Axis Compact Electric Compass Using Magneto-Impedance Sensor.

M. Yamamoto, Y. Honkura
Aichi Steel Corporation, Aichi-ken, Japan

Introduction

Recently, the electronic compass used in the mobile phone is attracted in order to realize map heading up service. Various types of the electronics compass for mobile phone use such as FG sensor, MI sensor, Hall sensor and MR sensor had been developed and put into market. Only the 3-axis electric compass based on Magneto-impedance (MI) effect developed by Aichi Steel corp. successfully gave best performance to achieve most excellent azimuth accuracy and smallest size as well as low price and low current consumption¹⁾.

The performance of this 3-axis electronic compass has been greatly improved since MI element is much downsized²⁾. Linearity is improved to 0.7%/FS, and hysteresis are much minimized. Accuracy of azimuth is improved from 5 degree to 2 degree.

MI type 3 axis compass³⁾

3-axis type of compact electronics compass has been developed and the internal structure is shown in Fig. 1. Its size is 3.5 × 4.0 × 1.0 mm. Different points of 3-axis type compass from 2-axis type compass is that its circuit has 3 MI elements, a switch alternating X, Y and Z type MI elements, 12 bit ADC and temperature sensor.

The downsized MI element shown in Fig. 2, has the size of 0.3 mm height, 0.6 mm length, 0.4 mm thickness, as small as one-third of previous one (0.93 mm length, 0.5 mm height, 0.28 mm thickness). Amorphous wire is also minimized from 20 μm diameter to 10 μm diameter. Hysteresis is much improved due to above improvements, so Linearity is improved.

When a pulsed current generated by the pulse generator circuit is run through the amorphous wire of 10 μm diameter, the amorphous wire is magnetized. When external magnetic field is applied, an voltage is induced in the pickup coil of MI sensor element. The voltage is proportional to the external magnetic field strength.

Fig. 3 shows excellent 0.7%/FS linearity characteristics with 10 μm diameter. Fig. 4 shows the azimuth accuracy of 2 degree when measured from 0 to 360 degree of the direction against North due to linearity improvement and circuit noise improvement.

Applications

The compass with azimuth accuracy of 2 degree has been developed. Today the compass is widely used in mobile phone to make map heading up service with GPS. It also is used in the automobiles and boats to show the azimuth. In future, it is expected that map heading up service will be improved to move more smoothly and quickly.

Giant magnetoresistive sensors for DNA microarray.

L. Xu¹, H. Yu², S. Han¹, S. Osterfeld¹, R. L. White¹, N. Pourmand², S. X. Wang¹

1. Materials Science and Engineering, Stanford University, Stanford, CA; 2. Stanford Genome Technology Center, Stanford University, Palo Alto, CA

Introduction

In recent years, Giant Magnetoresistive (GMR) sensors have shown a great potential as sensing elements for biomolecule detection^[1-3]. GMR sensors are sensitive, can be easily integrated with electronics and microfluidics, and can generate fully electronic signals. The GMR detection system is also cheap and can be easily made portable. All these advantages make the GMR sensors attractive over the fluorescent sensors. In this work, we successfully deployed GMR sensors in a prototype DNA microarray. Prior researches^[3] reported detection of DNA with concentrations above 1nM using GMR sensors. However, in order to be of use in most medical applications, the GMR sensors have to achieve a concentration sensitivity down to 1pM or less. With the help of “double modulation” detection technique and better surface chemistry, we accomplished detection of DNA samples down to ~10pM. Further research on microfluidics showed a great potential of improving the sensitivity to 1pM or below.

Materials and Methods

The principle of the GMR sensor is as follows: we coated the sensor surface with probe oligonucleotides. Target DNA sample was then applied onto the GMR sensor. Complementary target DNAs hybridized to the probe oligonucleotides and stayed on the sensor surface, while noncomplementary DNAs were washed away by rinsing. One end of the target DNA was modified to have a biotin group, which could bind to the streptavidin group attached to the magnetic nanoparticles. The stray field from the nanoparticles then generated the signal. A “double modulation” technique was used for signal readout. In this technique an AC magnetic field (frequency = 208Hz) was applied to excite the signal and an AC current (frequency = 500Hz) was passed through the sensor for signal readout. The interaction between the AC field and AC current generated a peak at 708Hz in the frequency domain. When the magnetic nanoparticles were at the vicinity of the GMR sensors, their stray field decreased the AC field sensed by the sensors, and therefore generated a signal change in the 708Hz peak. With this technique we could effectively reduce the 1/f noise, while eliminating electromagnetic interference at the same time.

Results

We performed DNA assays with various concentrations. The results are shown in Figure 1(a). The lowest concentration was 10pM, which gave signals of 2-4 uV. Scanning Electron Microscopy images of these assays were shown in Figure 1(b). The particle coverage corresponds well with the magnetic signal and the nominal DNA concentration.

One limiting factor for the sensitivity is the diffusion of target DNA to the sensor surface. To further improve the sensitivity, we are working on integrating microfluidics with the GMR sensors. Microfluidics can confine the DNA solution within the vicinity of the sensor surface. Therefore, the target DNAs do not need to travel a very long distance before binding to the probe oligonucleotides. This can potentially improve the sensitivity and decrease the assay time. Figure 2 shows Scanning Electron Microscopy images of some preliminary experiments. The particle coverage of 10pM assay with microfluidics was higher than the corresponding 10pM assay without microfluidics, and the 1pM assay with microfluidics also showed decent particle coverage, indicating that microfluidic GMR sensors are very promising.

Device for individualized detection of articles containing magnetic microwires based on ferromagnetic resonance.

P. Marín^{1,2}, D. Cortina³, J. Calvo³, A. Hernando^{1,2}

1. Instituto de Magnetismo Aplicado, Universidad Complutense de Madrid, Las Rozas, Spain; 2. Departamento de Física de Materiales, Universidad Complutense de Madrid, Madrid, Spain; 3. Micromag 2000, S.L., Las Rozas, Spain

Glass coated amorphous microwires, show very interesting magnetic properties with a broadband range of applications. Among others, they present ferromagnetic resonance and therefore absorb electromagnetic energy on the microwave region of the spectrum. These microwires consist of an inner core of an amorphous metallic composition of typically tens of μm coated with glass. They are obtained by an extracting melt-spinning technique, based on Taylor's classical method [1]. The study of microwave properties is very promising technologically. At the microwave region (approaching GHz range), the ferromagnetic resonance occurs. As a rule, and using Kittel equation [2] for ferromagnetic resonance frequency, it is necessary to apply a low frequency bias field to observe the effect.

The experiments realized show how a high frequency signal (1.28 GHz) can be modulated by the presence of a non bistable magnetic microwire. Figure 1 shows a draft of the set-up. A magnetic microwire of composition $\text{Fe}_{2.25}\text{Co}_{72.75}\text{Si}_{10}\text{B}_{15}$ is situated between Helmholtz coils connected to a low frequency (10 Hz) power supply. Simultaneously an electromagnetic wave (1.29 GHz), corresponding to microwire ferromagnetic resonance frequency, is generated by the emitting antenna. The modulated signal is received by the spectrum analyzer through the reception antenna. The magnetization precession at resonance frequency is only observed in a magnetically saturated microwire. So, the electromagnetic wave absorption occurs with bias field frequency.

Figure 2 shows the power level evolution with low frequency magnetic field intensity and the corresponding hysteresis loop. The temporal evolution of this signal is the consequence of high frequency signal modulation. The modulation effect can be modified by means of low frequency magnetic field intensity. The highest modulation is observed at microwire magnetic saturation. The modulation shape can be also modified by means of magnetic microwire low frequency hysteresis loop.

Based in this principle a device for individualized detection of articles containing magnetic microwires[3] has been developed. Figure 3 shows the electronic blocks diagramme. Each article to be identified has been tagged with a magnetic microwire characterised by certain hysteresis loop. The detection is based on high frequency signal modulation by means of ferromagnetic resonance. The signal detected by the reception antenna depends on microwire characteristics.

Two-domain model for orthogonal fluxgate.

M. Butta, P. Ripka

CVUT v Praze - FEL - MagLab, Praha, Czech Republic

Orthogonal fluxgate has been patented in 1951; this principle was almost forgotten as the main-stream large-size parallel fluxgate has shown lower noise and better stability. Orthogonal fluxgates based on microwires and planar microstructures reappeared recently; these devices have a good potential for miniaturization as they need no excitation coil. The working mechanism of the orthogonal fluxgate has not been fully understood yet. In [1] Primdahl proposed a simple model describing the rotation of the magnetization M , due to the circumferential magnetic field $H\Phi$. That model was based on the assumption of isotropy of the magnetic material; the first hypothesis Primdahl made, was the collinearity of B and H . Fundamental mode transverse fluxgate was later analysed by Sasada [2]; he has shown that this device cannot work without anisotropy.

Primdahl's model cannot be applied to the second-harmonic mode orthogonal fluxgates with electrodeposited magnetic wires. Measurement of the axial and longitudinal B-H loops (performed as explained in [3]) revealed significant anisotropy (as seen from Figs. 1 and 2). Moreover Primdahl's model cannot explain some typical features of the gating curves. Using this model we derived that the distance between the peaks in the gating curves depends linearly on the longitudinal field. We show that this is not true in the linear range of the fluxgate (Fig.3); the distance between the maxima changes only for high field values (i.e. comparable with the saturation field in circumferential direction). The observed distance between the peaks of the gating curve for small longitudinal field corresponds to the coercivity in circumferential direction (Fig.4).

We propose a new model for the mechanism of orthogonal fluxgates, suitable for electrodeposited magnetic wire. We assume the presence of easy axis of anisotropy in longitudinal direction, as typically found in these wires. Our model consists of two longitudinal domains with opposite direction of magnetization. The longitudinal field H_z causes domain wall movement from the central position: the domain with magnetization antiparallel to H_z becomes smaller (Fig.5). When we apply circumferential field $H\Phi$, both the domains rotate in order to achieve the minimum energy direction between the easy axis and the orthogonal direction, where $H\Phi$ lies (Fig. 6). In the longitudinal direction we obtain net magnetization M_z due to the difference between the magnetic moments projected into the z axis. M_z is maximum when the domain magnetization has longitudinal direction, and decreases when $H\Phi$ rotates them towards circumferential direction. The resulting gating curve is shown in Fig. 7. If we take into the account also the hysteresis in circumferential direction, this gating curve must be modified: the magnetization vectors are aligned in longitudinal direction when the circumferential component zero, i.e. for $H\Phi$ equal to positive and negative coercivity. The resulting gating curve will have two peaks (Fig. 8), in correspondence to the coercivity in circumferential direction, as proven by the measurements (Fig.4).

We have performed experiments to validate the model, especially to verify difference in the roles between $H\Phi$, which rotates the domains, and H_z , which moves the domain wall. The measurements were made on wires kindly supplied by S. Atalay [4].

This model can be also used to understand the coil-less fluxgate [5] mechanism, even if the detailed discussion about this topic is out of the scope of this paper.

Fabrication and characterization of magnetic tunnel junction field sensors with a Co_2MnSi thin film.

M. Masuda, T. Uemura, K. Matsuda, M. Yamamoto

Division of Electronics for Informatics, Graduate School of Information Science and Technology, Hokkaido University, Sapporo, Japan

Magnetic tunnel junctions (MTJs) with a Co-based full-Heusler alloy (Co_2YZ) thin film have attracted much interest as promising spintronic devices. We recently developed fully epitaxial MTJs with a Co_2YZ thin film and a MgO tunnel barrier, and demonstrated a relatively high tunnel magnetoresistance (TMR) ratio of 109% at RT (317% at 4.2 K) for $\text{Co}_2\text{Cr}_{0.6}\text{Fe}_{0.4}\text{Al}/\text{MgO}/\text{Co}_{50}\text{Fe}_{50}$ MTJs [1] and a TMR ratio of 90% at RT (192% at 4.2 K) for Co_2MnSi (CMS) /MgO/ $\text{Co}_{50}\text{Fe}_{50}$ MTJs [2]. In these MTJs, the free layer of Co_2YZ was formed in the lower electrode. This is because the use of the Co_2YZ film as a lower electrode enables *in-situ* annealing at temperatures higher than 400°C for improving the film quality before growing both the MgO tunnel barrier and pinned upper layer. For field sensor applications, however, it is much more desirable for a free layer to be formed in the upper electrode so that the size and shape of the free layer can be easily controlled. In this study, we fabricated fully epitaxial MTJs with a CMS free layer for the upper electrode, and demonstrated relatively high TMR ratios by carefully optimizing the annealing temperature of the CMS upper electrode. Furthermore, shape-dependent TMR characteristics were obtained for field sensor applications.

The fabricated MTJ layer structure was as follow: (from the substrate side) MgO buffer (10 nm)/ $\text{Co}_{50}\text{Fe}_{50}$ (40 nm)/IrMn (10 nm)/ $\text{Co}_{90}\text{Fe}_{10}$ (2 nm)/Ru (0.8 nm)/ $\text{Co}_{50}\text{Fe}_{50}$ (3 nm)/MgO barrier (2.5 nm)/CMS (50 nm)/Ru cap (5 nm)/(CoFe/MgO/CMS-MTJ). The CMS and $\text{Co}_{50}\text{Fe}_{50}$ films were used as an upper free layer and a lower pinned layer, respectively. The magnetization direction of the lower $\text{Co}_{50}\text{Fe}_{50}$ layer was pinned through exchange biasing. All layers in the MTJ structure were successively deposited on a MgO(001) single-crystal substrate in an ultrahigh vacuum chamber (with a base pressure of about 8×10^{-8} Pa) through the combined use of magnetron sputtering and electron beam evaporation. The MgO buffer and tunnel barrier were deposited by electron beam evaporation at 400°C and RT, respectively. Other layers were deposited by magnetron sputtering at RT. After the deposition of the CMS layer, it was annealed *in-situ* at 300°C for 15 min. We fabricated MTJs with both memory and sensor configurations by controlling the shape of the CMS free layer. In the memory configuration, the easy axis direction of the magnetization of the CMS free layer is parallel to that of the $\text{Co}_{50}\text{Fe}_{50}$ pinned layer, while they are orthogonal each other in the sensor configuration. After the microfabrication, the MTJs were annealed at 325°C for 60 min in a vacuum of 5×10^{-2} Pa under a magnetic field of 5000 Oe to fix the magnetization direction of the $\text{Co}_{50}\text{Fe}_{50}$ electrode.

X-ray pole figure measurements for CMS111 diffraction revealed that the CMS upper electrode layer was grown epitaxially with the L_2 structure. Figure 1 shows TMR major loops measured at RT and 4.2 K for a fabricated MTJ with a width (W) of 10 μm and length (L) of 50 μm . Here, the direction of L is defined along the pinned direction. The fabricated MTJs exhibited clear exchange-biased TMR characteristics with a relatively high TMR ratio of 94% at RT (209% at 4.2 K), a value comparable to that reported for MTJs with a CMS lower electrode and a $\text{Co}_{50}\text{Fe}_{50}$ upper electrode (90% at RT, 192% at 4.2 K) [2]. This result suggests that the annealing at 325°C improved the effective spin polarization of the CMS film without deterioration of the tunnel junction.

Figure 2 shows TMR minor loops at RT for MTJs with (a) $W = 5 \mu\text{m}$, $L = 25 \mu\text{m}$ (memory configuration), and (b) $W = 25 \mu\text{m}$, $L = 5 \mu\text{m}$ (sensor configuration). Anisotropic TMR characteristics,

depending on the junction shape, were obtained. As shown in Fig. 2(b), inducing the shape anisotropy with the easy axis direction perpendicular to the pinned direction weakened the hysteresis nature. A field sensitivity of approximately 0.4%/Oe was obtained. Although a weak hysteresis nature remained mainly due to a formation of multiple magnetic domain structures, device-size reduction to a sub-micron length would lead to a hysteresis-free, linear response.

High sensitive thin film wattmeter using magnetic thin film.

H. Tsujimoto, H. Toratani, Y. Deguti

Faculty of Engineering, Osaka City University, Osaka, Japan

Abstract

The new thin film wattmeter with the magneto resistance effect was proposed. The new magnetic thin film wattmeter has a three-layered structure (conductor film - insulation film - magnetic film). We could get the electric power consumption in the load from the voltage across the magnetic film along the current. We reported the circle shaped magnetic thin film wattmeter had the highest sensitivity by the results of computer simulation and the characteristic of the pre-production sample. We reported that the magnetic thin film wattmeter using the magnetic thin film was very useful as the embedded wattmeter into various electronic devices.

1. Introduction

Recently, the new energy such as the fuel battery is studying actively and the saving energy of the various electronic devices included household electric appliances are studying very much. The decrease of the electric power consumption is an important problem. The giant magnetic resistance effect (GMR) film has been applied to the magnetic recording head, the magnetic sensor, and so on, and those researches improve rapidly. We have reported that magnetic thin film device made by the magneto resistance effect film functions as a multiplier, a modulator and was used for the miniature wattmeter. The structure of the element is shown in the figure 1.

The characteristic when the form of the thin film wattmeter was made to change was analyzed. And the characteristic of the thin film wattmeter with a high sensitivity was studied with this paper.

2. Simulation and experiments

Fig.1 shows the basic structure of the thin film wattmeter by the magnetic thin film.

The thin film power meter has a three-layered structure. The top layer is a conductor film, the intermediate layer is an insulation layer and the bottom layer is a magnetic thin film with a magneto resistance effect. This power meter has two inputs and an output. One input is the current (I_1) that flows through a load and another input is the current (I_2) in proportion to applied voltage to the load. The current I_1 flows the top layer of the thin film wattmeter and the current I_2 flows in the magnetic film. The output is the voltage drop of the magnetic film along the current I_2 . The output voltage relates the electric power consumption in the load. The output characteristic of the thin film wattmeter was simulated and the output characteristic of the pre-production sample was measured.

The top layer of the pre-production thin film power meter is a conductor film (Cu: 25 μ m), the intermediate layer is an insulation film (Polyimide film: 25 μ m) and a bottom layer is magnetic thin film (MR film: 0.1 μ m). The width of the pre-production thin film power meter is 5mm and length is 21mm. When the electric power consumption in the load increased from 0 W to 70 W, the output of the wattmeter increased linearly from 0.32 V to 1.2 V. The frequency characteristic of the wattmeter was flat in the range of 2 kHz.

The changes of the resistance of the several wattmeters from the circle to the square were studied. Fig.2 shows the simulated characteristic of the resistance changes of the circle shaped wattmeter and the square shaped wattmeter when the input current I_1 applied. The current I_2 was 1mA. The diameter of circle wattmeter was 20 mm and the size of the square wattmeter was 20mm x 20m. The change of the resistance of the circle wattmeter was larger than that of the square wattmeter. Fig.3 shows the characteristic of the resistance changes of the pre-production film wattmeter. The change of the resistance of the circle wattmeter was larger than that of the square wattmeter. As

shown in Fig.1, the resistance change of the circle wattmeter of Fig.3 was about twice larger than B in the same as the result of Fig.2.

3. Summary

The new thin film wattmeter with the magneto resistance effect was proposed. We showed that we could get the electric power consumption in the load and that the circle shaped magnetic thin film wattmeter had the highest sensitivity. We reported that the new wattmeter was very useful as the embedded wattmeter.

Acoustic Interferometer Based on Magnetostrictive Delay Lines.

C. Petridis¹, V. Vassiliou¹, M. Kollár², E. Hristoforou¹

¹ Mining and Metallurgy Engineering, National Technical University of Athens, Athens, Greece;

² Electrical Engineering and Information Technology, Slovak University of Technology in Bratislava, Bratislava, Slovakia

This work presents an acoustic interferometer with absolute position measurement ability, based on the magnetostrictive delay line (MDL) technique actuated by sinusoidal elastic microstrains generated on the MDL. These microstrains produce a voltage output across a search coil, depend on the position of this coil with respect to the excitation coil and being a superposition of the main propagating acoustic wave and the two reflected waves from the respective ends of the MDL. Determination of the position is accomplished by measuring the phase of individual harmonics of the voltage induced due to propagating magnetoelastic waves.

The position sensor is illustrated in Fig. 1. It comprises of a magnetostrictive $\text{Fe}_{77.5}\text{Si}_{7.5}\text{B}_{15}$ ribbon, to act as MDL and two coils made of enameled copper wire. Sinusoidal current is transmitted through the excitation coil. The sensing or search coil is connected with a lock-in amplifier for the output signal conditioning and processing.

The generated microstrains are governed by a Gaussian-type dependence on the applied field as was shown in [1]. Following our MDL model, it can be seen that the induced voltage is proportional to

$$V_i \propto 1 + k_0 \sin(2\omega t - 2kl) - \sin(4\omega t - 4kl) \quad (1)$$

where k_0 and k are constants and l is the distance between the two coils.

Having set the excitation coil in a fixed position, then at a given excitation frequency, the change of the position x of the search coil results in a change of the induced voltage. Filtering particular harmonics one can record the amplitude or the phase of the 2nd or the 4th harmonic of the voltage induced in the sensing coil.

Change of the position of the search coil was checked by a laser interferometer during experiments. Figure 2 illustrates the 4th harmonic dependence on the distance in arrangement shown in Figure 1, at 30 kHz excitation frequency. The linear dependence as predicted by (1) can be observed, that is the proof of the absolute position ability measurement. The non linear behaviour at small displacements is due to the presence of ambient field caused by the excitation coil.

Figure 3 illustrates the phase dependence of the 2nd harmonic. A quazi-linear response can also be observed for this case. Figure 4 illustrates the dependence of the amplitude of the 4th harmonic, showing a non monotonic response (also qualitatively predicted by our model) that is clearly not suitable for measuring purposes. It is also evident that sensing of the 4th harmonic phase gives somewhat better results than that of 2nd. The sensitivity of the sensor, provided that the excitation coil is firmly fixed in position and well shielded, has been determined to be better than $5 \mu\text{m}$. Such a sensitivity and the ability of measuring the absolute position of the search coil, makes the sensor able to operate in numerous applications.

2D magnetic sensor based on planar Hall effect and surface nano-structuration.

J. Briones, F. Montaigne, M. Hehn, G. Lengaigne, D. Lacour

Laboratoire de Physique des Matériaux, Nancy-University, CNRS, Vandoeuvre lès Nancy, France

A topological modulation of magnetic thin films can induce magnetic anisotropy originating from magnetostatic energy. The lateral modulation can be obtained by self-organization (ex. growth on step bunched substrates), either by a top-down approach (anisotropic chemical etching for V-grooves fabrication). The use of e-beam lithography allows us to achieve a better control of the modulation. Such a way, it is possible to change locally the periodicity and the direction of modulation. This can be used to elaborate 2D magnetic sensors based on the Hall planar effect. We will show that we have succeeded in realizing wavy shaped Si substrates with periodicities as low as 200 nm. An AFM picture recorded on a $\text{Ni}_{80}\text{Fe}_{20}$ thin film deposited on a prepared surface with a periodicity of 300 nm is presented in the figure 1 inset. First, we have investigated the magnetic properties of several magnetic multilayers taking profit from their specific electronic transport properties. Indeed, the combination of anisotropy of magneto-resistance measurements (AMR) in different configurations with numerical simulations is a powerful tool to extract informations about the magnetic behaviour of our thin films. Without any modulation, our films always present an intrinsic anisotropy. We have demonstrated that patterning the substrate can counter this anisotropy and even impose a different easy axis of magnetization. AMR curves presented on the figure 1 show how we electrically determined the easy axis direction. The top and bottom AMR curves were obtained on NiFe films deposited on the same substrate but with orthogonal modulation directions. The black curves were recorded with a field applied along the current. On the contrary, the grey curves were obtained with a field applied in a direction perpendicular to the current. From this set of measurements, we can conclude without any ambiguity that the easy axes of magnetization are along the step direction in both cases. Moreover, the effect of thermal annealing under different field conditions has been studied. Once the control of local anisotropy by surface nano-structuration demonstrated, we have taken a step forward in designing and then developing a bidimensional magnetic sensor based on planar Hall effect. An optical photograph of the magnetic sensor is presented in the inset of figure 2. The two active parts composing the sensor can be distinguished at center of macroscopic electrical leads patterned by a standard UV lithography process. The two active parts are composed of a thin NiFe layer deposited on wavy shaped substrate. The modulation directions are orthogonal for each part of the sensor thus, each of them has a sensitive direction perpendicular to the other. This allows to determined both the amplitude and the direction of an in-plan magnetic field. The figure 2 presents the electrical response of one part of the sensor as a function of an magnetic field applied along its modulation direction. It can be noticed that the Hall planar effect delivers a linear response in the low field range as expected. More over the measure sensitivity is as high as 75 V/T.A. To conclude, we have been able to demonstrate the concept of a high precision bidimensionnal magnetic sensor based on the combination of planar Hall effect and surface nano-structuration.

Advanced Techniques for Modelling and Detection of Cracks in Hot Wire Steel.

R. Marklein, M. Rahman

Department of Electrical Engineering and Computer Science, University of Kassel, Kassel, Germany

Abstract

This paper presents innovative and advanced electromagnetic techniques for the in-line inspection of hot wire steel. The hot wire inspection procedure is performed with the eddy current (EC) sensor technique. Any type of crack on the upper surface of the steel wire disturbs the eddy current distribution, which can be detected by the eddy current sensors. However, the eddy current distribution is only weakly influenced by cracks, which are parallel to the wire, so-called longitudinal cracks. The conventional eddy current sensors cannot detect these cracks properly. To detect such longitudinal cracks a number of new EC sensors have been developed and successfully tested. Different numerical methods – the finite element method (FEM) and the boundary element method (BEM) have been used to model this NDT situation. The presented work is a part of the so-called INCOSTEEL project which is sponsored by the European Commission through the Research Fund for Coal and Steel (INCOSEEL: In-line quality control of hot wire steel - Towards innovative contactless solutions and data fusion).

Statement of the Problem of Hot Wire Steel Inspection

The production of long steel products like steel wires, rods and bars within the steel market is subjected to very strict specifications, with regard to quality and reliability as well as in terms of increasing productivity. Non-destructive testing (NDT) techniques are widely used for quality assurance in steel manufacturing, e.g., for the detection and evaluation of all potential types of internal and surface defects. The goal of the project called INCOSTEEL is to optimise the in-line detection of transversal and longitudinal defects produced in the manufacturing process of hot wire steel of diameter $D = 6 - 42$ mm. Material assessment is carried out at a temperature of $1000^\circ - 1200^\circ$ C at a rolling speed of up to 120 m/s. The aim of this presentation is to discuss the electromagnetic modelling techniques and to present the results of different EC sensors, developed for the INCOSTEEL project.

Simulation Results of Eddy Current (EC) Sensors

In this section the modelling of the detection of a crack with a point-coil (p-coil) sensor is reported (see Fig. 1). A p-coil sensor consists of a group of small elementary coils (see Fig. 1 a). Each element has the height of 3 mm and the diameter of 3.1 mm (see Fig. 1 b). 260 turns of copper wire is wound over a ferrite core to form a single element. In Fig. 1c the elements marked as 2 and 3 work as the receiving coils, while the other lone element works as the excitation coil. The simulations are performed by a 3-d eddy current simulation tool called Faraday, which is based on BEM technique.

Fig. 1c shows a snapshot of the detection process. 50 mm of a steel wire of the diameter $D = 31$ mm has been simulated here. The size of the crack is: length $l = 10$ mm, width $w = 1$ mm and depth $d = 1$ mm. The eddy current distribution on the steel surface is displayed in the bottom of Fig. 1c, where a excitation frequency of $f = 74$ kHz is used. The obtained voltage in the sensor coil is recorded and plotted on the top of Fig. 1c to determine the response of the sensor when a crack crosses the sensor.

Figure 2: a) Experimental A-scan, b) synthetic A-scan. Fig.2 shows the simulated A-scan (b) compared to the measured A-scan (a), which validates the predicted A-scan.

Thermally modulated flux concentrator for minimizing 1/f noise in magnetic sensors.

W. Wang, Z. Jiang

Electrical Engineering, University of Wisconsin - Milwaukee, Milwaukee, WI

Magnetic Tunneling Junction (MTJ) based field sensor is a promising candidate for ultra-low field sensing [1-2]. However, MTJ's 1/f noise limits the low frequency sensing resolution, which is important in many medical and military applications. This impact can be minimized by modulating the field at 1kHz or higher frequency. Currently, the MEMS based modulation approach demonstrates the best results [1]. However, this approach suffers from low modulation efficiency and remaining magnetization in flux concentrator which impacts the sensing limitation. We propose a novel thermally modulated flux concentrator to overcome those two limiting factors.

The proposed approach is to replace the flux concentrator material from Permalloy or CoZrNb to magnetic materials with Curie points around sensing temperatures (room temperature in most cases). The field modulations can be achieved by modulating the flux concentrator's temperature around its Curie point, i.e. modulating the flux concentrator between ferromagnetic materials and paramagnetic material. Since the the flux concentrators are thin plates, their vertical thermal diffusion time is very short. If we take MnAs as an example, 20°C temperature range around Curie point (45°C) is enough for modulation purpose. The low frequency magnetic fields can be modulated at 1 kHz or higher frequencies, where the 1/f noise of magnetic sensors is greatly reduced.

The material selections are based on application temperatures. For the room temperature applications, MnAs (T_c at 45°C) and LaMn₂Ge₂ (T_c at 42°C) are the potential candidate materials.

Although MEMS based modulation approach has a much wider operation temperature range, the proposed approach has following advantages for the applications with predictable operation temperature, such as, medical applications.

(1) Higher Signal to Noise Ratio

Since there is no flux concentrator motion required, the gap between the flux concentrator and the magnetic sensor can be much smaller in the proposed approach. It's reported that 35% gain increasing was resulted from 0.5μm gap reduction (5μm to 4.5μm) between magnetic sensor and the flux concentrator [3]. In contrast, the MEMS flux concentrator motion requires quite large margins on the minimum gap between magnetic sensor and flux concentrator. This margin inevitably leads to low modulation efficiency.

Since the downstream electronic measurement circuits filter out all signal components not at the modulation frequency, the final measured data are the modulated field components only. Higher modulation efficiency leads to higher signal level and signal to noise ratio.

(2) higher sensitivity

Although the easy axis of the flux concentrator is often designed in perpendicular to the field to be measured, there is still some hysteresis along flux concentrator's hard axis [3]. Similar hysteresis is expected in Permalloy based flux concentrator. Such hysteresis contributes to the sensitivity limit for low field sensing. In contrast, the proposed thermal modulation does not have such hysteresis. Magnetic domains are nucleated during each thermal modulation cycle.

(3) Less fringe fields from modulation driving sources

One possible implementation scheme for the proposed approach is to use laser beam to deliver the thermal energy and to remove the heat by passive cooling through substrate. Such implementation can separate the modulation driving source far from the magnetic sensor. Therefore, the fringe field from modulation driving source can be reduced significantly.

We've done a preliminary thermal analysis on the proposed thermally modulated flux concentrator. The flux concentrator is a pair of 50nm thick MnAs thin film trapezoids on 300μm thick GaAs substrate, whose bottom surface temperature is at 25°C. ANSYS thermal analysis results demonstrate successful field modulation with repeated heating and cooling cycles at 1kHz. The average heating power needed is 44mW for the flux concentrator with the same size of the MEMS based flux concentrator [1]. The cycle to cycle temperature repeatability is also simulated.

The left axis of Figure 1 shows the simulated temperature waveform within one cycle during stable operation. The stable operation condition is reached when the temperature difference between the start and end point of a given heating/cooling cycle is less than 0.01°C. The right axis of Fig. 1 shows the field amplification factor within one cycle under a constant external magnetic. The field amplification is completely lost when the temperature of the flux concentrator reaches Curie temperature (45°C for MnAs).

In summary, We presented a novel thermal modulation approach to reduce 1/f noise in MTJ based magnetic field sensor. The thermal analysis demonstrates the first order feasibility of the proposed approach.

We report scanning gate measurements that incorporate silicon probes coated with magnetic films to make the first measurements of the room temperature (RT) response of semiconductor Hall crosses to local applied magnetic fields under various local gate conditions [1-4]. The crosses consist of 400 nm and 100 nm wide shallow quantum wells of InAs (fig 1), and local gating was achieved by applying a voltage to the scanning probe. We have found that under certain small gate voltages (V_g) the devices are strongly responsive to the local magnetic field, and that the results may be described using a finite element model. This approach is useful for the design and optimization of local magnetic field sensors, such as those based on extraordinary magnetoresistance (EMR) effects.

The shallow AlSb / InAs / AlSb 2DEG used for these devices was 80 Å from the surface, and had a RT Hall mobility of 7,070 cm²/Vs and carrier concentration of 1.9E12 /cm², as measured from mesoscopic van der Pauw samples. The RT mean free path of the electrons in the 2DEG is thus estimated to be around 160 nm. We have built Hall crosses with critical dimensions down to 100 nm (spanning the diffusive / ballistic transport transition) using electron beam lithography in combination with ion milling, and measured their response to uniform currents and magnetic fields, as well as to non-uniform magnetic and electric fields by scanning probe microscopy with both magnetic and non-magnetic probes.

In the 400 nm devices at low V_g we observe around 8 times higher Hall voltage signal when a magnetic probe rather than a non-magnetic probe is used. This magnetic signal is centered in the Hall cross, rather than having peaks at each of the corners as is observed for the non-magnetic probes, and reverses in sign when the magnetization of the probe is reversed. With the same magnetic probe, as V_g is increased the central signal peak elongates along the cross diagonal, changing orientation when V_g or magnetic probe field orientation is reversed (fig 2). These results are reproduced using a FEM model (fig 3) that incorporates the Lorentz force in the conductivity tensor and a standard parabolic semiconductor band structure with a band gap of 0.38 eV and Fermi level in zero bias at 0.15 eV above the conduction band. We also measure an asymmetry in the strength of the peak Hall voltage for positive and negative gate voltages, indicating that the resistance increase with negative bias is larger than the resistance decrease with positive bias.

In the 100 nm devices, in which we are entering the ballistic regime, we observe somewhat different behavior. At low V_g a single peak signal is observed at the center of the cross, as for the 400 nm devices. However, as V_g is increased in magnitude in either direction, the signal disappears from the center of the cross and flares instead in the voltage arms of the device (fig. 4), a behavior we have not observed in the 400 nm crosses. It appears that since the leads are now on the same length scale as the probe (probe diameter ~ 50 nm) we are able to scatter carriers into the voltage leads even when the probe is a considerable distance from the center of the cross.

Field dependence of the magnetocaloric effect beyond the mean field approach: a universal curve for the magnetic entropy change.

V. Franco, A. Conde

Department of Condensed Matter Physics, Sevilla University, Sevilla, Spain

Currently, the field dependence of the magnetocaloric effect is being studied intensively for two main reasons. From a fundamental point of view, the analysis of this field dependence for different types of materials can give further clues of how to improve the performance of refrigerant materials for the magnetic field range employed in actual refrigerators (generally 10 to 20 kOe). From a practical point of view, the knowledge of the laws governing the field dependence of the magnetic entropy change can provide tools for making plausible extrapolations to magnetic field values outside the available experimental range in some laboratories.

The theoretical description of this field dependence has usually been made on the basis of a mean field approach, which corresponds to a power law of the field with an exponent $2/3$. However, the authors have recently demonstrated that experimental data do not necessarily follow this $H^{2/3}$ law [1]. Instead, a relationship between the value of the exponent and the critical exponents of the material has been demonstrated.

The study of materials with a second order phase transition allowed finding a universal curve for the magnetic entropy change: not only the different magnetic entropy change curves of a material measured up to different maximum applied fields collapse onto a single curve, but also series of alloys with the same values of the critical exponent collapse onto the same curve [1,2]. This universal curve was initially derived in a purely phenomenological way using results of soft magnetic amorphous alloys. More recently, it has been applied to several crystalline rare earth alloys [3] and its existence can be demonstrated theoretically.

In this talk, the different procedures for constructing the universal curve will be described, outlining the demonstration of its existence and considering the particularities of different universality classes. This will be illustrated with experimental results from different types of materials, ranging from transition metal based alloys to rare-earth crystals and from bulk materials to nanoparticles. The practical applications of the universal curve (a tool for making extrapolations in temperature or field, and for enhancing the resolution of the experimental data close to the peak entropy change) will also be discussed.

1. Electromagnetism Department, INRIM, Torino, Italy; 2. Physics Department, Politecnico di Torino, Torino, Italy

Materials presenting Magnetocaloric Effect (MCE) are promising candidates for magnetic cooling technologies because they exhibit a first order magneto-structural phase transition induced by magnetic field which is accompanied by a large entropy change [1]. The accurate measurement of the entropy change as a function of temperature and field allows to classify an MCE material according to its refrigeration capacity. Materials presenting an inverse magnetocaloric effect MCE effect have been recently discovered: the inverse MCE leads to an endothermic response under the application of field [2-4].

In this work we analyze a polycrystalline Ni-Mn-Sn sample which, depending on the initial sample temperature, presents both positive and a negative MCE features. Ni-Mn-Sn provides an ideal test for experimental and analytical methods used to estimate the MCE effect, since both endothermal and exothermal effects occur in a rapid sequence, in conjunction with a martensite to austenite magnetostructural phase transition.

In order to compare different experimental methods with a phenomenological model, direct isothermal entropy changes, $\Delta s(\Delta H)_T$, were determined using a calorimeter based on Peltier cells measuring the heat flux associated to an applied magnetic field up to $\mu_0 H = 2$ T [5]; the same experimental setup was used for calorimetric temperature scans in the presence of magnetic field to estimate Δs during heating/cooling at constant field. Adiabatic temperature changes $\Delta T(\Delta H)$ of the same sample were measured using a custom built cryomagnet insert under an applied field up to 7 T [6,7].

The phenomenological model used is based on the idea that the magnetic field changes the magneto-structural phase transition temperatures displacing the curves $s(T;H)$ in the (s,T) plane. The $s(T;H)$ curves are described by the following function (Fig.1):

$$s(T;H) = s_0 + c_{p0} \ln(T) + (c_{p1} - c_{p0}) \int (1/T) x(T;H) dT + s_L(H) x(T), \quad (1)$$

where c_{p0}/T and c_{p1}/T are the heat capacities of the martensite and austenite respectively, s_L is the entropy discontinuity at the first order phase transition and $x(T)$ is the volume fraction of the sample occupied by the austenite. All these parameters can be determined fitting the integral of the specific heat in zero field measured by a calorimetry scan. The dependence from H and T of x gives the phase transition evolution. In the specific case: $x(T;H) = 1/2 \tanh[a(T - T_0(H))] + 1/2$ and $T_0(H)$, the phase transition temperature, is inversely proportional to H in the case of the inverse magnetocaloric effect discussed here (Fig.1). The $\Delta s(\Delta H)_T$ and $\Delta T(\Delta H)$ can be predicted by comparing two $s(T;H)$ curves made at two different fields, H_1 and H_2 : $\Delta s(\Delta H)_T = s(T;H_2) - s(T;H_1)$; $\Delta T(\Delta H) = T(H_2; s) - T(H_1; s)$.

In order to achieve the same initial conditions, each $\Delta s(\Delta H)_T$ was measured after a zero field cooling to 270 K in order to completely transform back the sample to the low temperature martensite phase.

The comparison between isothermal entropy changes $\Delta s(\Delta H)_T$ and adiabatic temperature changes $\Delta T(\Delta H)$ measured at different temperatures T and field $\mu_0 H = 2$ T shows that these two methods lead to results directly comparable in the framework of a simplified phenomenological model. The experimental $\Delta s(\Delta H)_T$ and $\Delta T(\Delta H)$ peaks in the temperature range of the inverse magnetocaloric effect, presented in Fig.2, can be predicted by the model assuming $T_0(\mu_0 H) = T_0 - [0.14 \times (\mu_0 H)]$ K

and $s_L(\mu_0 H) = s_L + [0.04 \times (\mu_0 H)^2]$ J kg⁻¹ K⁻¹. The determined behavior of T_0 , which shifts to lower temperatures as H increases, is in perfect agreement with temperature scan results performed at fields up to 2 T.

Model output of the $s(T)$ curve in the martensite-to-austenite phase transition (increasing temperature). In the case of inverse magnetocaloric effect, the phase transition temperature is decreased by field application.

Isothermal entropy change ($\Delta s(\Delta H)_T$) and adiabatic temperature change ($\Delta T(\Delta H)_s$) measured during heating experiment for $\mu_0 H = 2$ T have been plotted together in order to highlight their consistency.

Magnetocaloric properties of $\text{La}(\text{Fe},\text{Co},\text{Si})_{13}$ bulk material prepared by powder metallurgy.

M. Katter, V. Zellmann, G. Reppel, K. Uestuener
Vacuumschmelze GmbH & Co. KG, Hanau, Germany

Introduction:

The good magnetocaloric properties of intermetallic compounds based on $\text{La}(\text{Fe},\text{Si})_{13}$ make these materials very promising candidates as working materials for magnetic refrigeration at room temperature [1]. The preparation of bulk material by conventional casting is hindered by the very sluggish formation of the cubic NaZn_{13} crystal structure which requires a long term homogenization heat treatment. The homogenization time can be reduced considerably by melt spinning or strip casting [2,3]. However, with these techniques no bulk material can be produced. It is the aim of this paper to describe an industrially applicable powder metallurgical production route to prepare fully dense bulk magnetocaloric materials with tightly controlled Curie temperatures based on $\text{La}(\text{Fe},\text{Co},\text{Si})_{13}$.

Experimental:

Commercial powders of elemental Fe and Si were mixed with coarse powders of LaH_2 as well as various La-Fe-Co-Si pre-alloys and milled in kg quantities in a jet mill under inert gas to a particle size of $< 5 \mu\text{m}$ according to Fisher Sub Sive Sizer (F.S.S.S.). The powders were compacted either isostatically or in a die applying a pressure of 1.5 to 4 t/cm^2 . The green parts were then sintered between 1333 K to 1433 K for 4 to 8 h under inert conditions. The density of the bulk samples was measured by the Archimedes principle. The magnetic properties were determined in a vibrating sample magnetometer for magnetic field strengths up to 17 kOe in the temperature range from 160 K to 370 K. The magnetic entropy change was deduced from these data according to the Maxwell relation $\Delta S = - \int (\partial M / \partial T) H dH$. For some samples also the adiabatic temperature change for a field variation of 17 kOe was measured directly in an electromagnet.

Results and Discussion:

Fig. 1 shows the magnetocaloric properties of ternary $\text{La}(\text{Fe}_{0.893}\text{Si}_{0.107})_{13}$ sintered at 1413 K to a density of 7.19 g/cm^3 . The sample shows a strong first order type magnetocaloric effect. The magnetic entropy change for a field change of 16 kOe amounts to 21.9 J/kgK at a temperature of about 193 K. For this field change, the width of the entropy peak at half height, ΔT_{WHH} , is determined to be 6.6 K. The properties compare well with values reported in the literature for conventional cast, melt spun and strip cast material [1-3]. For a similar sample, a maximum adiabatic temperature change of 4.2 K was measured for a field change of 17 kOe. It is worth to mention that according to these results the NaZn_{13} structure was obviously formed during reactive sintering out of the elemental starting powders without any melting and casting at all.

In order to increase the Curie temperature, the starting powders were blended with Co-rich powders, pressed in a rectangular die and sintered at 1353 K to a density of about 7.2 g/cm^3 and dimensions of about 23x19x13 mm. With the Co content increasing from 4.6 to 10.2 wt.%, the peak temperature increases from 254 to 336 K, the magnetic entropy change decreases from 9.4 to 4.5 kJ/kgK and ΔT_{WHH} increases from 13.7 to 31.5 K (all values for $\Delta H = 16$ kOe), s. Fig. 2. The values are consistent with results reported for conventionally cast bulk samples [4]. The blocks can be machined by conventional techniques to the shapes required in magnetic refrigeration prototypes.

Conclusions:

Applying the powder metallurgical technique of reactive sintering, fully dense magnetocaloric bulk material based on La-Fe-Co-Si was produced in kg quantities. The Curie temperatures were tailored to the commercial relevant range from about 250 to 340 K. Such materials are available to

be tested in magnetic refrigeration prototypes. The production process can be upscaled to industrial levels straight forward.

In this paper we present the magnetic and microstructural results we obtained on the $\text{Gd}_5\text{Ge}_2\text{Si}_2$ compound doped with about 4.5 atom percent Sn; this doping level is 4 times that of our earlier studies [1, 2]. In the previous studies, we observed that doping the $\text{Gd}_5\text{Ge}_2\text{Si}_2$ compound with about 1% of either Fe, Al, Co, Cu, Ga, or Mn greatly reduced or completely eliminated its hysteretic losses as well as changing the characteristics of its magnetocaloric effect peak, whereas the same amount of Sn doping had instead negligible effect [1, 2]. The results of the present study provide valuable insight concerning the mechanism that different types of metal dopants have in both reducing the hysteresis losses and changing the characteristics of the magnetocaloric peak of $\text{Gd}_5\text{Ge}_2\text{Si}_2$.

The $\text{Gd}_5\text{Ge}_{1.8}\text{Si}_{1.8}\text{Sn}_{0.4}$ Sn-doped sample for this study was similarly prepared by arc melting as in the previous studies [1, 2]. Figure 1 shows respectively the room temperature x-ray powder diffraction spectra of the Gd_5Si_4 (A), $\text{Gd}_5\text{Ge}_2\text{Si}_2$ (B), and (C) $\text{Gd}_5\text{Ge}_{1.8}\text{Si}_{1.8}\text{Sn}_{0.4}$ compounds; the spectrum of the Gd_5Si_4 is analogous to that of $\text{Gd}_5\text{Ge}_2\text{Si}_2$ below its structural phase transition temperature of ~270 K. Thus, Figs. 1(A) and 1(B) respectively illustrate the typical orthorhombic and monoclinic structures of the undoped $\text{Gd}_5\text{Ge}_2\text{Si}_2$ below and above the phase transition temperature. Fig. 1(C), instead, shows that the spectrum peaks of the Sn-doped sample closely match those of the $\text{Gd}_5\text{Ge}_2\text{Si}_2$ monoclinic phase, with the exception of a slight shifting of the peaks to lower angles. This suggests that, at room temperature, similar to $\text{Gd}_5\text{Ge}_2\text{Si}_2$, the structure of the Sn-doped sample is monoclinic, except for a slight increase in the lattice parameters. These x-ray diffraction results are consistent with the corresponding microstructure and magnetic results. In fact, from the analysis of the SEM and EDS results, we concluded that about half of the tin atoms reside within the large grains of the main phase, while the other half segregated to the grain boundaries. This is different from what we had previously observed on $\text{Gd}_5\text{Ge}_2\text{Si}_2$ doped with either Fe, Al, Co, Cu, Ga or Mn, where the resulting microstructure consisted of a parent majority phase and a minority phase (rich in silicon and the respective doping element) [1, 2]. Consequently, the formation of the minority phase resulted in the partial depletion of Si from the majority phase [1, 2]. Figure 2 respectively show the M vs. H loops (A) and the entropy change, ΔS_m vs. T plot (B) for a $\Delta H=5$ T of the $\text{Gd}_5\text{Ge}_{1.8}\text{Si}_{1.8}\text{Sn}_{0.4}$ sample. Similar to what we previously observed in $\text{Gd}_5\text{Ge}_2\text{Si}_2$ doped with about 1% Sn, the M vs. H loops shows the presence of hysteretic losses in the same temperature range where the ΔS_m vs. T plot exhibits a large magnetocaloric peak. Except for minor differences, the magnetocaloric properties (the hysteresis losses, Fig. 2A and magnetocaloric peak, Fig. 2B) of $\text{Gd}_5\text{Ge}_{1.8}\text{Si}_{1.8}\text{Sn}_{0.4}$ are basically the same as those of undoped $\text{Gd}_5\text{Ge}_2\text{Si}_2$.

To conclude, therefore, the present study conducted on $\text{Gd}_5\text{Ge}_{1.8}\text{Si}_{1.8}\text{Sn}_{0.4}$ re-enforces the previously stated hypothesis that the formation of a minority phase, rich in Si and the corresponding doping element is key for eliminating the hysteresis losses in $\text{Gd}_5\text{Ge}_2\text{Si}_2$ by suppressing the first-order orthorhombic-to-monoclinic field-induced phase transition. In fact, the x-ray diffraction spectra of the Fe-doped compound (taken both below and above the phase transition temperature, ~270 K) showed that it retained an orthorhombic structure in the 10-320 K temperature range. Consequently, the orthorhombic-to-monoclinic crystal phase transition did not occur [3], thereby preventing the reverse field-induced monoclinic-to-orthorhombic phase transition. Instead, for the present Sn-doped sample we showed that its magnetocaloric characteristics were similar those of the undoped

$\text{Gd}_5\text{Ge}_2\text{Si}_2$. This finding, combined with the SEM and EDS results, showing that about half of the Sn atoms in $\text{Gd}_5\text{Ge}_{1.8}\text{Si}_{1.8}\text{Sn}_{0.4}$ reside substitutionally in the Ge-Si crystal lattice sites, while the other half segregated to the grain boundaries. This prevented the formation of a distinct minority phase (rich in Si) that is critical in both greatly reducing the hysteresis losses and changing the characteristics of the magnetocaloric peak of $\text{Gd}_5\text{Ge}_2\text{Si}_2$.

Pure graphite, the stable crystalline allotrope of carbon at room temperature and ambient pressure, is known to exhibit a strong and anisotropic “textbook” diamagnetism, due to its delocalized π electrons. Nevertheless, in the last two decades more or less clear evidences of ferromagnetic behavior in carbon at room temperature have been reported. And more recently [1-4], new findings of this kind have appeared in the literature, as the presence of ferromagnetic signals in proton-irradiated Highly-Oriented Pyrolytic Graphite (HOPG). In the latter experimental work, the analysis of possible magnetic impurities has been much more rigorous as to overcome the natural scepticism arose by the former experiments. Experiments employing x-ray magnetic circular dichroism [4] have demonstrated that the magnetic order in the investigated system originates only from the carbon π -electron system. Moreover, several theoretical works seem to support the importance of disorder [5] and/or of vacancy-hydrogen complexes [6] for the appearance of magnetic moments in graphite, though the true physical origin of these effects are unknown.

On the one hand, the possibility of intrinsic long range magnetic order in carbon is appealing from a fundamental scientific point of view because its existence in systems containing only s and p electrons is unusual and would demonstrate the importance of correlation effects between these electrons. On the other hand, the interest in producing organic materials with magnetic properties is obvious. Therefore, we have undertaken a joint research line to study this subject, by making use of the 5 MV tandem ion-accelerator hosted by the CMAM in the Universidad Autonoma de Madrid. At the same time of the ion implantation, the Particle-Induced X-ray Emission (PIXE) technique allows to determine in situ the amount of magnetic impurities in the sample, a crucial issue given the weakness of the reported ferromagnetic signals. The possible existence of ferromagnetism in HOPG samples has been studied [7] through SQUID magnetometry and Magnetic Force Microscopy (MFM).

In our first experiments [7] on this matter, we cut HOPG samples with a typical surface area of 17 mm² and 0.2 - 0.3 mm thick, using clean diamond wire. We conducted ion-beam irradiation of protons of 3 MeV energy, in high vacuum. Montecarlo SRIM simulations indicate a corresponding implantation depth of 75 micrometers for the H⁺ ions (protons). Spot size was here always about 1 mm². Total irradiated doses ranged 40 - 1000 microcoulomb. Using a SQUID magnetometer from Quantum Design, we have measured the magnetization of the samples, with magnetic fields applied parallel to graphene planes. After subtracting the linear (negative) diamagnetic background, in all cases a (weak) ferromagnetic curve was observed, with the sample of intermediate irradiation dose, 200 microcoulomb, exhibiting the higher ferromagnetic signal [7]. Nevertheless, we found somewhat surprisingly that also a non-irradiated HOPG sample exhibit some ferromagnetic signal, comparable with the samples of lesser magnetization. We discard the possibility of all this behaviour being due to magnetic impurities, since our PIXE experiments performed on some of these samples always gave concentrations below 10 ppm of Fe element, and undetectable for other mag-

netic impurities. Furthermore, a measurement performed under the very same conditions in a sample of powder graphite exhibited a perfect diamagnetic curve.

More recently, we have developed a specific sample holder, made of oxygen-free high-conductivity copper, appropriate to be employed both in the SQUID and in the ion-beam chambers, and to be transferred between them. So, the necessity is avoided of neither to touch the sample nor to add or remove any gluing substance, therefore assuring that one can really measure the net difference in magnetization of the graphite sample before and after ion irradiation, in these cases where the magnetic signals are so weak. Newly prepared HOPG samples present the same ferromagnetic curves as the former samples (with saturation magnetization around 4 10⁻³ emu/g and coercive fields around 200 Oe) even before irradiation, likely due to the presence of defects and/or hydrogen already in the unirradiated samples. Finally, we have conducted experiments using protons, alpha particles and carbon as irradiating ions, under different conditions of energies and fluences, and discuss their effects on the magnetization curves of HOPG samples.

Photocatalysis is a fantastic way to clean facilities, living environments, and even reduce the spread of infections such as SARS in hospitals [1,2]. One of the most crucial tasks in water-works technologies is a separation of the photocatalyst from the liquid phase. Therefore we have designed a system constituted of a photoactive medium (nanocrystalline TiO_2 in the anatase modification) adsorbed on magnetic particles, which can be easily removed from the liquid phase by an applied magnetic field. In this work, we focus on magnetic characterization of the magnetically separable photocatalysts formed of maghemite nanoparticles coated by anatase. A series of samples was prepared by a novel synthetic technique described in [3] using a suspension of maghemite nanoparticles coated by citric acid (the final functional material was named after it: MagCit). The photoactive TiO_2 layer was subsequently adsorbed on the nanoparticle surface. The obtained products were dried and finally annealed at 100°C, 200 °C and 400 °C, respectively, to improve crystallinity of the originally amorphous anatase phase. The series of composites was characterized using powder X-ray diffraction (XRD), scanning electron microscopy (SEM), BET analysis, and transmission electron microscopies (TEM, HRTEM). The XRD patterns revealed maghemite phase (with C-type subcell) and anatase modification of TiO_2 . The magnetite nanoparticles are covered by TiO_2 forming a needle-like microstructure (Figure 1, right panel) with high surface area, which is definitely more efficient for photocatalysis, than a compact monolayer. Magnetic properties of the prepared series were investigated by means of magnetization measurements in the temperature range 2–350 K and magnetic fields up to 7 T. As an example, the room-temperature hysteresis loops are shown in Figure 2 (left panel). We observed no significant effect of the final heat treatment on the saturated magnetization value. The temperature dependence of the zero-field cooled (ZFC) and field-cooled (FC) magnetization (Figure 2, right panel), respectively, suggest a minor effect on the final particle size; the furcation point on the ZFC and FC curves appears at slightly lower temperatures for the MagCit sample annealed at 200 °C, probably caused by a slightly enhanced agglomeration rate in case of the higher annealing temperature.

In addition, an interesting feature was observed when comparing the maghemite particle size obtained from the XRD and magnetic measurements, respectively. While the characteristic scattering domain (equivalent to the mean particle size) in the XRD experiment is about 5 nm, results of the magnetic measurements suggest much larger particle size (20 nm). Detailed investigations by HR TEM method revealed, that the material consists of ~ 100 nm agglomerates of 3–5 nm maghemite nanoparticles, which are regularly coated by the anatase porous layer. Additional measurements of the a.c. magnetic susceptibility supported the idea of strongly interacting small magnetic particles (superferromagnetism [4]) with a typical range of the inter-particle interaction of about 25 nm.

Elastic model for complex hysteresis in molecular magnets.

C. Enachescu¹, L. Stoleriu¹, A. Stancu¹, A. Hauser²

The spin transition solids [1] are molecular compounds belonging to the class of molecular magnets and are switchable between two states in thermodynamic competition: the diamagnetic low spin state (LS) and the paramagnetic high spin state (HS). The switch is accompanied by complex hysteretic processes that are fundamental for applications in information storage.

To understand this complex behavior, several models of the spin transition have been elaborated, involving short and long range interactions of elastic origin similar to the ones used in ferromagnetic materials [2]. The long range elastic interactions are due to the pressure which appears in the finite crystal as a consequence of the molecule volume and shape change. The short range interactions between two molecules depend on the distance between them and their orientation in the network.

In this paper we model the hysteretic behavior in a spin transition compound, considering the molecules situated in a bi-dimensional lattice and interacting with elastic connecting springs (fig. 1). The system size in the simulations is up to 4000 molecules.

At high temperature/low pressure the molecules are in the HS state; by changing the temperature or the pressure they can pass to LS state, if able to exceed the elastic force from closest springs. The switch of individual molecules is checked randomly with a Monte Carlo procedure. When a molecule changes its state, the new equilibrium positions of all molecules are calculated. The transition of a molecule from a state to another corresponds to a change of its volume and modifies the global interactions in the system and finally the position of each molecule (fig.2). The transition depends on random factors, but also on the status of the neighbor molecules.

In fig.3 we present experimental and simulated thermal hysteresis at various pressures, and we notice that they are in a good agreement. As expected, increasing pressure shifts the hysteresis loop in temperature.

In a previous work, we proved that the First-order reversal curves method provides valuable information on the interaction distributions in the sample [3]. In fig. 4, one can see simulated FORC curves for the thermal hysteresis at different pressures; we notice that the distribution is shifted towards higher temperatures but its shape does not change.

This model is able to correctly describe hysteresis in temperature and pressure. In the full paper, the role of interactions will be explained and a study concerning the size effects will be presented.

Field-dependent ($M(H)$), thermoremanent (TRM) magnetization and AC susceptibility ($\chi'(T)$, $\chi''(T)$ and $\chi''(\chi')$) experiments of one dimensional chain-like molecular magnet $[\text{Fe}^{\text{II}}(\Delta)\text{Fe}^{\text{II}}(\Lambda)(\text{ox})_2(\text{phen})_2]_n$ have been performed.

The $M(H)$ behavior of the sample measured at different temperatures has been shown in Fig. 1. The nature of $M(H)$ loop is found to be varied with changing temperature. viz., i) for $T > T_m$ (see the 10 K curve, $T_m \sim 8.6$ K)^[1,2], the $M(H)$ curves behave like paramagnets; ii) for $7 \text{ K} < T < T_m$ (see the 8 K curve), the magnetization value dramatically increases only with small applied field and shows no hysteresis loop, which is the characteristics of a soft magnet or superparamagnet (SPM); iii) for $2 \text{ K} < T < 7 \text{ K}$ (see the 2.5, 3 and 5 K curves), finite-size hysteresis loops have been observed, accompanied by a discontinuous step occurred at ~ 7000 Oe. The coercive field increases with decreasing temperature, however, the discontinuous step seems to be unchanged with varying temperature. iv) for $T \leq 2 \text{ K}$ (see the 2 and 1.7 K curves), the area of the hysteresis loop further increases and the discontinuous step becomes unobvious. In cases of i), ii) and iii), high field magnetization shows no hysteresis and no saturation even at our highest applying field 7 T. This behavior may be due to the presence of a paramagnetic region in our sample. In addition, the discontinuous step does not always present if we use different scanning interval. Since in most studies on molecular magnets, the field-sweeping rate is tuned to obtain different hysteresis loops^[3], we achieve the same behavior by tuning the interval of scanning field. This is a strong evidence that our sample shows relaxation behavior.

TRM data of our sample measured at temperatures between 1.9~10 K can be quantitatively analyzed with stretched exponential^[3,4].

$$m(t) = m_0 \exp[-(t/\tau)^\alpha] + m_r$$

The relaxation of magnetization could be considered as a consequence of thermal activation between spin states. At low temperature, the temperature dependence of relaxation time, τ , can be fitted by Arrhenius law^[5].

$$\tau = \tau_0 \exp[E_a/k_B T]$$

Fig. 2 (solid square) shows the $\ln(\tau)$ versus inverse T plot which represents Arrhenius law in form of straight line. The solid lines represent the Arrhenius law fitting results. From Fig. 2, two clear straight line portions are evident, signifying two distinguishable regions. The boundary between the regions is indicated by a gray square. The derived activation energies (E_a/k_B), comes out to be 70.9 and 47.1 K in high (I) and in low (II) temperature regions, respectively. The τ in the gray square region is too long to measure in laboratory, so that it is hard to determine the exact boundary temperature. Another approach to find out the boundary is the method used for SPMs. In SPMs, a char-

acteristic freezing temperature (T_f) is of the order $E_a/25k_B$ ^[5]. Although our sample is not SPM, the spin dynamics of most molecular magnets is quite similar to SPMs. Applying this relation to our results, gives $T_f^{\text{I}} \sim 2.8 \text{ K}$ and $T_f^{\text{II}} \sim 1.9 \text{ K}$ in region I and II, respectively. Therefore, we can propose a reasonable boundary temperature at 2.8 K, where the spins were frozen, leading to very long τ .

AC susceptibility is also a powerful tool to study the relaxation behavior. In $\chi'(T)$ and $\chi''(T)$ curves are found to be strongly frequency-dependent and the τ value has been calculated by oscillation frequency. In case of $\chi''(\chi')$ (Cole-Cole plot), the τ value can be obtained by Debye model^[6,7]. They're also plotted in Fig. 2 with open square and open triangle for temperature- and frequency-dependent magnetization curve, respectively.

Both DC and AC measurements show that there are at least three different phases below T_m . It might be caused by the structure frustration or presence of fractional cluster spin glass state.

Spintronics applications require the use of highly spin-polarized current sources. For this purpose, half-metallic ferromagnets, such as various magnetic oxides, have been integrated in spintronic devices and high magnetoresistance values have been recorded. However, their Curie temperatures are too close to room temperature for technological applications. Another possibility to achieve high spin-polarized sources at high temperatures consists of doping the host materials with magnetic ions, as in diluted magnetic semiconductors [1]. We have followed this approach by doping metallic non-magnetic (La,Sr)TiO₃ with 1,5% Co (CoLSTO) [2,3,4]. The samples were grown by pulsed laser deposition with a frequency-tripled Nd:YAG laser ($\lambda = 355$ nm) on SrTiO₃ (STO) (001) substrates.

In order to understand the origin of the magnetic properties of our CoLSTO samples (they revealed magnetic hysteresis cycles [2]), we have performed a broad study including micro- and nano-structural characterization, as well as the measurement of the spin-polarization through the analysis of the magnetotransport properties of tunnel junction devices using CoLSTO electrodes. Quite interestingly, we have found that growth conditions, such as oxygen partial pressure, have a relevant influence on the magnetic properties, probably revealing the role of defects, including oxygen vacancies, on the mechanisms leading to magnetic correlations.

It is well known that phase segregation is a major concern in these magnetic diluted systems [5]. Bearing this in mind, we have performed an extensive structural analysis of our samples combining X-ray diffraction, high-resolution transmission electron microscopy (HRTEM), electron energy-loss spectroscopy (EELS) and Auger spectroscopy. None of these experiments showed any direct evidence for the presence of Co-rich clusters.

To measure the spin polarization, CoLSTO tunnel junction devices with micro- and nanometric size have been fabricated either by optical lithography or by real-time resistance-controlled nanoindentation with a conductive AFM tip [6]. The measurements of the tunnel magnetoresistance (TMR) for the CoLSTO/LAO/Co junctions gave the TMR values up to 20%. (TMR is defined as $TMR = (R_p - R_{ap})/R_{ap}$, where R_p and R_{ap} are the resistances in parallel and anti-parallel configurations). Our TMR results enabled us to deduce that a spin polarization for the CoLSTO system is up to 80% [4]. We will address the dependence of the TMR and spin polarization on temperature and applied voltage bias, as well as the influence of growth conditions on the magnetotransport properties of these tunnel devices, with particular emphasis on the growth oxygen pressure.

Finally, in order to analyze better the origin of the ferromagnetism and spin polarization of CoLSTO films, we have carried out XMCD (X-ray Magnetic Circular Dichroism) experiments at the Co and Ti L_{2,3} edges. These experiments have provided us with useful insights into the electronic states at the Co and Ti sites, which are relevant to understand the microscopic origins of the magnetic properties of the CoLSTO films. In particular, we will show that the spectral signature of both XAS (X-ray Absorption Spectroscopy) and XMCD indicates that cobalt is in ionic states.

Diluted magnetic semiconductors, with (Ga,Mn)As as a typical model material, have attracted attention for last few years due to the carrier-mediated origin of the ferromagnetism. This special feature enables to control the magnetization of the material also by changing the concentration of the carriers, which is very important property for future applications in semiconductor spintronics [1]. The carrier population can be modified by different methods, among which the optical injection of the carriers is the simplest one. The methods of ultrafast laser spectroscopy use a strong femtosecond laser pulse to inject the carriers and a second time-delayed laser pulse to probe the evolution of light-induced changes of material properties. Both carrier dynamics and magnetization dynamics can be investigated by these methods. In addition, the effects connected with the spin polarization of photoinjected carriers can be studied if the optical pumping is performed with circularly polarized light.

We measured simultaneously the dynamics of the sample reflectivity change and the polar Kerr rotation (KR) signal. The investigated samples were thin layers of ferromagnetic $\text{Ga}_{1-x}\text{Mn}_x\text{As}$ ($x = 0.058$) grown by low temperature MBE. The experiments were performed both on as-grown and annealed samples. The easy axis of magnetization is in-plane for both samples. In Fig. 1 (a) we show the KR signal induced by linearly and circularly polarized laser pulses with no external magnetic field applied. The signal consists of two components. One part is strongly sensitive to the polarization of laser pulses and decays monotonously with the time delay. The second part is the same for linear and circular polarization of pump pulses and shows an oscillatory behavior. The polarization-independent part of the KR signal can be fitted well by a damped harmonic function superimposed on a time-dependent background for time delays above 50 ps. The deviation of the fit from the measured data in early stages of the dynamics indicates that ~ 50 ps is the time that is necessary for the oscillations to develop after the carriers are photoinjected. The duration of this transition region agrees well with the measured dynamics of the sample reflectivity change that reflects the (nonradiative) lifetime of the photoinjected carriers (electrons in particular). The dynamics of KR observed in the as-grown and the annealed samples are compared in Fig. 1 (b). The sample annealing resulted in an increase of both the oscillation angular frequency (21 GHz and 24 GHz in the as-grown sample and the annealed sample, respectively) and the oscillation damping time (0.4 ns and 1.1 ns, respectively) – those features are apparent in the Fourier transform of the oscillations as a small shift of the peak position and a considerable narrowing of the peak width (see Inset in Fig. 1 (b)). The frequency of oscillations is also strongly dependent on the laser intensity and the lattice temperature (not shown here).

The oscillatory behavior of the KR signal in (Ga,Mn)As was recently observed by two groups [2], [3]. The explanation of its origin was first proposed by A. Oiwa et al. [2]. They ascribed this phenomenon to the magnetization precession due to the change in magnetic anisotropy, which was induced by the presence of photoinjected carriers. On the other hand, J. Qi et al. [3] suggested that the reason for the anisotropy change could be the laser-induced temperature increase. In our case the estimated relative change of carrier concentration is only $\Delta p/p \sim 0.07\%$, which is highly improbable to cause any detectable change in the magnetic anisotropy. The observed relatively slow development of the oscillations also strongly favors the latter mechanism. Moreover, the duration

of this transition region agrees well with the measured time when phonons were emitted by the non-radiative recombination of photoinjected carriers (i.e., when the lattice was heated up). The oscillation damping is connected with the Gilbert parameter in the Landau-Lifshitz-Gilbert equation [1]. Therefore, the suppression of the damping in the annealed sample reflects the improvement of sample magnetic properties by the annealing. Nanowires are an important class of nanostructures with potential applications in a wide field of disciplines. Thus, such structures can be employed as building blocks for electronic or optoelectronic devices or as highly accurate sensors. This is the reason for which the field related to the preparation of nanowires of various materials increased strongly during the last decade.

The template approach represents one convenient method for obtaining nanowires with controlled morphology. As an example metallic nanowires with magnetic properties such as giant magnetoresistance or anisotropic magnetoresistance were prepared using electrochemical deposition in anodic alumina or ion track nanoporous membranes.

In this report we present our results on preparation of ZnO nanowires doped with cobalt. The templates employed were polycarbonate ion track templates, 30 micrometers thick, with cylindrical pores (diameters ranging from 50 to 600 nm).

Electrochemical deposition was employed to fill the pores with the desired material, cobalt doped ZnO nanowires being fabricated. The deposition was performed using a zinc nitrate bath (0.1 M) with the addition of cobalt nitrate (0.06 M). In figure 1 the electrochemical polarization and the chronoamperometric curves are presented for the cathodic processes employed in cobalt doped ZnO nanowire preparation.

As can be noticed from the figure 1(a) the deposition starts at a potential of approximately -600 mV with a plateau between -760 mV and -900 mV followed by a strong increase of the current towards more electronegative potentials. We assume that a cobalt deposition takes place at more positive currents while the formation of ZnO becomes predominant at more negative potentials.

The results of SEM investigations and of the EDX analysis are presented in figure 2 for two deposition potentials, -800 and -1050 mV. As can be noticed the deposition at lower potentials leads to the formation of wires with a cobalt content of up to 5% while for more electronegative values of the deposition potential the cobalt content is almost negligible.

Magnetic measurements were performed up to this moment on two samples, one with highest Co concentration (5%) for a sample deposited at -760 mV and one with the lowest Co concentration (<1%) for a sample deposited at -1050 mV.

In figure 3 is shown the magnetic moment dependence as a function of temperature for the sample containing 5% Co, measured at 1 T, with the magnetic field aligned perpendicular to the length of the nanowires. This temperature dependence is typical for all the samples measured, at both perpendicular and parallel orientation of the magnetic field with respect to the nanowires' length, and at both 1 T and 50 mT field values. There are no magnetic transitions visible, no significant difference between the two curves at high or low temperatures, and the behaviour is as expected for a Curie or Curie-Weiss paramagnet.

In summary, arrays of ZnO nanowires doped with up to 5% Co were prepared. The approach allows an excellent control of dopant concentration by choosing the appropriate deposition potential. Thus, by this approach, one can tune the Co content in the nanowires by choosing the appropriate voltage of deposition. Such behaviour can lead to the preparation of multisegment or multi-layered nanowires in a similar manner in which multilayered metallic nanowires with GMR properties were obtained. The nanowire samples show paramagnetic-like temperature dependences.

However, field loops at very low (2.5 K) temperatures suggest there may be a proportion of the Co moments that do not behave as purely paramagnetic $J=9/2$ ions, and this may indicate some weak interactions between them. Measurements are underway for samples doped with higher cobalt concentration.

INTRODUCTION

Spintronics is an emerging research field that tries to utilize electron spins as information processing media, which has attracted lots of attention due to its possibilities to enhance the performance of conventional electronic devices [1]. Diluted Magnetic Semiconductors (DMS) are among the most promising candidates for spintronics [2]. While low-dimensional DMS nanostructures are also highly pursued recently, attributing to their unique properties and the applications in nanodevices. Transitional-metal-doped ZnO nanowires or nanorods with room temperature ferromagnetism have been fabricated via various methods, though the origin of room temperature ferromagnetism is still being debated. In this article, room temperature ferromagnetic FeCo-codoped ZnO nanorods were fabricated by CVD and substitution of Fe and Co into ZnO lattice has been confirmed.

EXPERIMENT

The FeCo-codoped ZnO nanorods were synthesized following the procedures reported in previous experiments on Mn-doped ZnO nanowire arrays [3]. High purity Zn foil (Alfa Aesar, purity 99.998%, 0.25 mm thick), $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ powder (Alfa Aesar, purity 99.998%), and FeCl_2 powder (Alfa Aesar, 99.99%, ultra dry) with atomic ratio Zn:Fe:Co = 10:1:1 were used as source materials. Silicon wafers with 300 nm oxide layer were used to collect the products at the downstream and 10 mm away from the source materials. Different deposition temperatures have been used (in this report, 650°C, 750°C, 850°C). The morphologies of as-synthesized FeCo-codoped ZnO nanostructures were investigated by Carl Zeiss 1530 VP field-emission scanning electron microscope (FESEM). The transmission electron microscopy (TEM) and nanoprobe EDS were performed using a FEI Tecnai F20-UT microscope. The magnetic properties of the samples were measured by Quantum Design MPMS-5S superconducting quantum interference device (SQUID) magnetometer.

RESULTS AND DISCUSSION

Fig. 1(a) shows a low magnification TEM image of an (Fe, Co)-codoped ZnO nanowire prepared by CVD. Fig. 1(b)-(c) are the corresponding high resolution TEM images, which show that the nanowire is single crystalline with growth direction along the c-axis. The EDS spectra (Fig. 1(d)) reveal that both Fe and Co are detected at all sampling points and the concentrations of Fe and Co are about 0.8 at%. Fig. 2 is the M-H hysteresis loops of the nanorods at 300 K. The diamagnetic contributions from the silicon wafers have been subtracted from the data. The specimen grown at 850°C has the strongest room temperature ferromagnetic properties with a saturation magnetization ~0.012 emu/g and a coercive field ~100 Oe at room temperature. The results indicate that high deposition temperature will attribute to better magnetic doping and enhance the ferromagnetic ordering, however, once the deposition temperature exceeds certain level (in our case, 850°C).

Magnetic interactions in (Zn,Co)O - effects of heat treatment and co-doping.

M. Wikberg¹, P. Svedlindh¹, V. Coleman^{2,3}, R. Knut², O. Karis², D. Iusan², B. Sanyal², G. Westin³

Diluted magnetic semiconductors have attracted interest both from theoretical and experimental standpoints. In particular transition metal doped ZnO has drawn much attention due to both theoretical predictions and experimental reports of high ferromagnetic transition temperatures (T_c). However, overall the reports have been inconclusive with results ranging from room temperature T_c to the absence of ferromagnetism even at cryogenic temperatures.

An extensive program has been set up to investigate magnetic interactions in Co-doped ZnO and its dependence on annealing conditions and co-doping. In this report we focus on (Zn,Co)O films with 5% Co and in some cases 0.8% Al, prepared by spin coating acetate-based solutions on quartz substrates. Subsequent heat treatments at 600°C or 800°C were performed for 1 hour in ambient or Ar atmosphere. The surface morphology and crystal microstructure of the films were investigated with scanning electron microscopy and grazing incidence X-ray diffraction. These investigations revealed uniform, polycrystalline, and most importantly phase pure films.

Electronic structure measurements were performed on beamline D1011 at MAX lab, Sweden, including X-ray absorption spectroscopy (XAS), X-ray photoelectron spectroscopy (XPS), resonant photoemission spectroscopy (RPES) and X-ray magnetic circular dichroism (XMCD). XMCD was recorded at remanence and showed no dichroism, which is consistent with magnetization results. We find that the Fermi level is located very close to the conduction band in all samples, indicating large amounts of intrinsic defects resulting in highly n-doped systems and also explains why Al co-doping does not affect the Fermi level. Occupied Co states can clearly be seen at the valence band (VB) edge by comparing ZnO and (Zn,Co)O XPS spectra. This conclusion is supported by the RPES results. Al co-doping does not significantly alter the VB of the pure ZnO but reduces the number of Co states at the VB edge for (Zn,CoAl)O. Increased absorption of Co 2p edges upon Al co-doping suggests that less Co 3d states are occupied. This leads to the conclusion that Al co-doping pushes the VB Co 3d states to higher energies.

Magnetic measurements were performed in a Quantum Design MPMS-XL Superconducting Quantum Interference Device (SQUID) magnetometer. Susceptibility ($\chi=M/H$) vs. temperature (T) was studied between 375 K and 2 K, applying a field of 500 Oe. Magnetization (M) vs. field (H) measurements were performed at 2 K between 30 kOe and -30 kOe. The χ vs. T measurements reveal, for all measured samples, a paramagnetic behavior with no sign of a spin ordering even at the lowest temperature investigated. A clear difference in the magnetic response for different annealing conditions has been observed, with a higher magnetic moment for the samples annealed at 800°C (see inset Fig 1a) as well as an additional increase in magnetic moment if annealed in Ar flow instead of in ambient air, Fig 1b. Contrary to expectations, the carrier induced ferromagnetic behavior through Al-doping is not detected. Instead, a distinct decrease in magnetic moment is observed. The absence of magnetic hysteresis but a tendency of magnetic saturation for high applied fields, indicate that the dominating behavior is superparamagnetic and not ferromagnetic.

The electronic structure calculations have been performed using a Green's function Korringa-Kohn-Rostoker (KKR) method within the atomic sphere approximation (ASA). The local density approximation was used along with a spdf basis. In order to treat disorder, the Coherent Potential Approximation (CPA) has been employed. The Heisenberg pair-exchange parameters were calculated using the methodology of Liechtenstein et al.¹.

From calculations, values for the projected magnetic moment on Co atoms are $2.57\mu_B$ with short-range ferromagnetic Co-Co interaction. The calculated chemical interaction indicates a tendency for Co-clustering. The tendency for Co clustering is increased by co-doping with Al. If clustering is favored, some regions of the samples will contain a large concentration of Co. To simulate this situation, we have investigated the magnetic interaction for CoO in the zinc-blende and naturally occurring rock-salt structures. We have found that antiferromagnetic interaction between Co atoms is favored in both structures.

The absence of remanence in both XMCD and SQUID measurements together with the indication from calculations that cluster formation is favored, a tendency increasing with Al co-doping, lead us to the conclusion that the dominating magnetic behavior in (Zn,Co)O is superparamagnetic through the formation of randomly distributed Co-clusters. Although structural data indicates phase pure samples, regions rich in Co-content can not be excluded based on our structural and electronic characterizations. For clusters holding uncompensated spins at the surface, a small effective moment will be measured at low fields (Fig 1 b, moments derived from the low field slope of the M vs. H curves), well below the calculated value for Co atoms. The spins align with increasing field yielding the high magnetic moments detected at high fields (Fig 1b).

Growth of $\text{Zn}_{1-x}\text{Mn}_x\text{O}$ nanorod arrays in aqueous solution.

Y. Fang, J. Persson, M. Göthelid, J. Åkerman

Department of Microelectronics and Applied Physics, Royal Institute of Technology, Stockholm-Kista, Sweden

$\text{Zn}_{1-x}\text{Mn}_x\text{O}$ nanorod arrays have been grown in aqueous solution. The as-grown nanorods were characterized by scanning electron microscopy (SEM), X-ray energy-dispersive spectroscopy (XEDS) and X-ray photoelectron spectroscopy (XPS). The structure of $\text{Zn}_{1-x}\text{Mn}_x\text{O}$ nanorods is hexagonal and the arrays are uniform on the substrate. The incorporated Mn is around 5 at.% and the chemical state of the dopants is Mn^{4+} .

Dietl et al. have theoretically predicted that Mn doped p-type ZnO could show room temperature ferromagnetism [1]. To date, Mn- and Co-doped ZnO 1D nanostructures have been synthesized and room temperature ferromagnetism has been experimentally demonstrated by a number of research groups [2,3,4]. In this work, we use an aqueous solution method to grow $\text{Zn}_{1-x}\text{Mn}_x\text{O}$ nanorod arrays, which is novel, easy and energy saving.

$\text{Zn}_{1-x}\text{Mn}_x\text{O}$ nanorod arrays were grown on Si substrates coated with a magnetron sputtered ZnO seedlayer. The substrates were first cleaned by acetone, isopropanol and deionized water in an ultrasonic bath. 100 ml of 0.025 mol/l zinc acetate dihydrate ($\text{C}_4\text{H}_6\text{O}_4\text{Zn} \cdot 2\text{H}_2\text{O}$) and 100 ml of 0.025 mol/l $\text{Mn}(\text{NO}_3)_2$ solution were mixed together with ammonia ($\text{NH}_3 \cdot \text{H}_2\text{O}$) slowly added into the solution until the pH value reached 10.8. The solution was heated to 90°C using a hot plate. Finally, the substrate was suspended in the solution for 3 hours with the sputtered surface facing down. As shown in Fig. 1, hexagonal nanorods with an average diameter of about 80–100 nm are clearly observed and the uniformity of the rods is good. Mn XEDS peaks in Fig. 2 indicate that the nanorods contain Mn and the atomic percent is about 5%. The nanorods also contain C about 5–6 at.%. One of the reagents in the aqueous solution is zinc acetate, which probably introduces the C contamination into the nanorods. In Fig. 3, the XPS data obtained for the wires can be observed both before and after annealing at 120°C and Ar sputtering for surface cleaning purposes. For Zn and O, the peaks are evident, and the only difference after sputtering and heating is that the intensity is increased and the water peak has disappeared. The sputtered lines show that the chemical state of the Mn is Mn^{4+} , according to the position of the peak at around 643 eV. The fact that the Mn has changed its state from $2+$ (in the solution) to $4+$ is evidence that points to the conclusion that the Mn has been incorporated into the ZnO lattice, and that it is not just residual Mn on the surface of the sample.

In summary, we have successfully grown uniform hexagonal $\text{Zn}_{1-x}\text{Mn}_x\text{O}$ nanorod arrays by using an aqueous solution method, which to the best of our knowledge has not yet been reported in the literature. XEDS and XPS spectra indicate that the Mn has diffused into the ZnO rather than it being residual Mn deposition on the surface. The investigation of the ferromagnetism of these $\text{Zn}_{1-x}\text{Mn}_x\text{O}$ nanorods is underway.

1. Material Physics, KTH, Kista, Sweden; 2. Departement of physics, Uppsala University, Uppsala, Sweden

ZnO is a promising material for new photonic applications due to its large bandgap (3.3eV) and exciton binding energy (60meV). It has also been predicted to be ferromagnetic at room temperature [1], providing a path to semiconductor spintronic applications. Several studies show that ferromagnetism is present in ZnO at room temperature: Ferromagnetic ZnO has been fabricated in bulk and in thin films with pulsed laser deposition [2] (a result disputed by [3]) and also by sputtering [4]. According to Dietls [1] theory the ferromagnetism in ZnO is mediated by holes in the case of Mn doping, thus co-doping with an acceptor species should increase the coupling between magnetic dopants and thus enhance the ferromagnetic behavior of the material. Room temperature ferromagnetism has indeed been shown by co doping where ZnO and Mn were sputtered in N₂ gas in order to introduce acceptors in the lattice [4]. Even though the majority carrier type was electrons, they argued that states introduced by the N acceptor mediated ferromagnetic coupling between the dopant atoms. It has been shown that the solubility of N is very low in ZnO even in a radical state [5], and that the presence of radical N species at the growth is important for an efficient doping. Therefore we propose to use a cyclotron resonance plasma source to enhance the number of N species present during sputtering growth.

The samples were prepared by co-sputtering of ZnO and Mn on Si substrates. The growth rates of each material was measured and adjusted to give a Mn concentration of 5at%. The sputtering gas was varied between Ar and N₂, and a cyclotron plasma source was used in order to enhance the incorporation of N acceptors in the ZnO. The sputtering chamber was evacuated to $\sim 10^{-8}$ mTorr base pressure before sputtering. Temperatures were varied between RT and 450°C. The sputtering pressure was set to 2.5 mTorr. The flow rate was set to a maximum value of 20 sccm. This value was chosen to maximize the number of radical N species from the plasma source [6]. The samples were characterized with an XPERT high resolution x-ray diffraction (XRD) system and a Quantum Design SQUID magnetometer. The x-ray photoelectron spectroscopy (XPS) data was acquired in a custom made XPS system. X-ray magnetic circular dichroism (XMCD) data was taken at the European Synchrotron Radiation Facility (ESRF) in Grenoble. The XMCD signal was measured with the field perpendicular to the sample.

The films show a highly oriented growth, where the Mn doped samples show a small shift in the XRD spectra. It is evident that the incorporation of the Mn and N creates a small lattice distortion. The SQUID measurements show a hysteretic M-H loop at room temperature and at 10K, where samples grown with N₂ and specifically the samples grown with a plasma source enhancement of the N species show the strongest magnetic moment.

When the samples are investigated with XPS we find a shift in the N 1s and Mn2p peaks of the samples. The strongest N and Mn peaks correlate with the SQUID measurements.

XMCD measurements on the other hand show a paramagnetic behavior without any hysteresis.

The correlation between the strong N 1s peak in plasma grown samples and the strong magnetic moment of these samples would indicate that the N state has a strong influence on the ferromagnetism in ZnO, however the lack of XMCD data to support this theory will question similar results obtained where no magneto-optical measurement has been provided.

Squid measurements of ZnO:Mn at 10K

Andreev and Optical Measurement of Spin polarisation in ZnO Based Dilute Magnetic Semiconductors.

J. R. Neal¹, K. Yates², A. J. Behan¹, D. S. Score¹, H. J. Blythe¹, A. M. Fox¹, L. F. Cohen², G. A. Gehring¹

1. Physics and Astronomy, The University of Sheffield, Sheffield, United Kingdom; 2. Blackett Laboratory, Imperial College, London, United Kingdom

Recently there has been considerable interest into dilute magnetic semiconductors (DMS) since they were predicted[1] to exhibit ferromagnetism at room temperature. This has been driven by the aim of finding a material from which spin polarised currents may be injected, manipulated, usefully extracted and are also compatible with existing semiconductor technology.

ZnO based DMS materials have been shown to exhibit room temperature ferromagnetism[2,3]. However, progress has not been straight forward, as many of the techniques employed to characterise these materials are unable to distinguish between genuine DMS behaviour and secondary phases or ferromagnetic clusters within a semiconductor.

This study is concerned with the determination of the polarisation of the carriers, as devices may only be realised when there is a useful polarisation of the itinerant electrons within the DMS.

Here we report the use of Andreev reflectivity to directly measure the polarisation of the conduction electrons in doped ZnO. Andreev reflection occurs at a superconductor/conductor boundary where conduction across the boundary may occur. By measuring the differential conductance the polarisation of the conductor may be determined.

We also report the use of optical magnetic circular dichroism (MCD) to show that the room temperature ferromagnetism in these samples is associated with the ZnO lattice. MCD is a spectroscopic technique that is able to probe the band structure of the samples. When there is a splitting or unequal spin population of an energy band it leads to a differential absorption of circularly polarised light. Hence MCD can be used to identify where the magnetic moments reside in a material.

The thin film Zn(1-x)Co(x)O samples co-doped with up to 1% Al studied were grown by pulsed laser deposition (PLD) on Al₂O₃ (0001) substrates with Co concentrations of 5%. SQUID hysteresis loops of the doped films all show room temperature ferromagnetism, as has been observed previously [4,5,6]. By co-doping with Al, the number of carriers in the thin film was increased to produce carrier densities in the region of 10²¹ cm⁻³ that exhibit metallic conductivity and large moments[7].

Figure 1 shows the Andreev spectrum for a 5% Co, 0.6% Al doped ZnO sample with a moment of 0.6μB/Co, grown at an oxygen pressure of 10⁻⁵ Torr, measured at 4.2K. The data is fitted for the ballistic regime and due to the high contact resistance, the spreading resistance is negligible. From the inset, which shows the reliability of the fit, it can be seen that the polarisation in the sample is 44%.

In order to check that the observed polarisation was not due to metallic Co clusters[8] the signal was measured at many points and no variation was detected.

The 300K MCD spectra, measured in a field of 0.5T, for a 5% Co and 0.6% Al doped ZnO film 240nm thick, with a moment of 0.4μB/Co, grown at 10⁻²Torr, is presented in fig 2. The large signal observed at the ZnO band edge (3.35eV) indicates that the ZnO band electrons are polarised and the observed ferromagnetism is intrinsic to the host ZnO and not due to defect phases.

Furthermore, the strength of the Co²⁺ d-d* feature at 1.95eV is larger than would be expected for paramagnetic Co²⁺ ions[9]. This indicates that the Co²⁺ ions experience a strong exchange field

from the ferromagnetism and hence we can rule out the possibility of Co clusters as the primary source of the observed magnetism[10].

To conclude, we have demonstrated that when Co doped ZnO is co-doped with Al to produce a suitably high carrier density the thin films can exhibit large moments. Also, the splitting of the ZnO conduction band gives rise to a substantial spin polarisation of the conduction electrons which have the potential for exploitation in spintronic devices.

Ferromagnetic semiconductors, as obtained by doping semiconductors with magnetic impurities, are of great interest due to their potential application for future spintronics devices. Titanium dioxide, TiO₂, is a wide band gap semiconductor. In addition it has a high refractive index and dielectric constant and excellent optical transmittance in the Vis-IR region. This is very suitable characteristics for electronic and optical applications. Adding to this the magnetic properties when doping with e.g. Fe may give rise to a suitable magnetic oxide such as transparent ferromagnetic semiconductor, which are appealing materials for magneto-optical devices. Depending on the fabrication technique, the magnetic properties may show strong differences ascribed to the different structures and magnetic ordering.

In this paper we present results on the magnetic properties of TiO₂ thin films implanted with ⁵⁶Fe ions. The films were grown by pulsed-dc magnetron sputtering in a argon/oxygen atmosphere using a titanium sputter target. The films were deposited onto silicon (100) wafers. Two sets of deposition were carried out; one with no external substrate heating (sample A), and one with the substrate heated to 573 K (sample B). The films thickness was about 400 nm in both cases. Structural analysis of the films was performed by means of grazing incidence X-ray diffraction measurements. The data revealed an essential amorphous TiO₂ film for sample A and a polycrystalline anatase film for sample B, see figure 1. The samples were implanted with 100 keV ⁵⁶Fe⁺ ions at room temperature to a total fluence of 1.3×10^{16} ions cm⁻². The implantation range is ~90 nm. The elemental depth profiles of the samples before and after implantation were analysed by ion beam analysis and XPS.

As a result of the ion implantation, the polycrystalline anatase film in sample B was modified, with a partial loss of crystallinity. The diffraction peaks reduced in intensity and even disappeared for some crystal planes. For the mainly amorphous film, ion implantation did not introduce any appreciable changes in the structure. There were no signals from the formation of Fe clusters or intermediate oxide phases nor was phase change appreciated in both types of implanted samples¹. Magnetic measurements were performed of implanted and un-implanted samples, using a Super Quantum Interference Device (SQUID) at 4 and 300 K. Un-implanted samples did not show any ferromagnetic behaviour, only diamagnetic and paramagnetic signals ascribed to the Si substrate and the sputtered TiO₂, respectively. Hysteresis loops for the Fe implanted samples are shown in figure 2 at the two temperatures after subtracting the above mentioned linear magnetic contributions. A ferromagnetic characteristic is observed and summarized in Table 1, i.e., coercivity field (H_c), remanence (M_r) and saturation (M_s) moments normalized to Bohr's magneton per implanted Fe atom.

The results for the two films show similar values of the coercive field and magnetic remanence. However, the essentially amorphous sample (sample A) presented an enhanced value of magnetization. An amorphization also appears in the initial anatase film (sample B) as an effect of the implantation and may also be the origin of the ferromagnetism in this sample. Reported results on doping TiO₂ with Fe presented different magnetic responses depending on phase, type of carriers, and vacancies or interstitials^{2,3}. Although stoichiometric TiO₂ contains only Ti⁴⁺ ions and is non-magnetic, unpaired 3d electrons in Ti³⁺ and Ti²⁺ ions, due to O defects, can potentially cause mag-

netism⁴ in addition with the Fe ions by superexchange interactions. The conclusion of the preliminary result is that the degradation of crystalline order may be an important parameter in the magnetic response of these implanted, room temperature ferromagnetic materials.

(Ga,Mn)As ultrathin films with high Mn concentration.

J. Deng^{1,2}, W. Wang¹, L. Chen¹, J. Lu¹, Y. Ji¹, J. Zhao¹

1. Institute of Semiconductors, Chinese Academy of Sciences, Beijing, China; 2. Department of Physics, University of Science and Technology of China, Hefei, China

In the past decade, diluted magnetic semiconductor (Ga,Mn)As films have attracted much attention for their potential application in future spintronic devices [1]. However, their Curie temperature T_c is much lower than room temperature, which hampers their practical applications. Recently, some groups studied magnetic properties of (Ga,Mn)As films with Mn concentration x larger than 0.1 and the thickness t less than 10 nm [2,3]. Although the T_c of 165~170 K of these ultrathin films is a little bit lower than the highest record of 173 K obtained in the thicker one [4], it is still widely accepted that the ultrathin thickness and high Mn concentration are key factors to increase T_c of (Ga,Mn)As. So far, only few work has been carried out on (Ga,Mn)As ultrathin film with high Mn concentration. In this work, to comprehensively understand magnetic property of (Ga,Mn)As ultrathin film, we have grown a series of (Ga,Mn)As films with $t = 7$ nm and $x = 0.14$ at different growth temperature T_s by molecular-beam epitaxy, and investigated magnetization and magneto-transport property of them systematically.

All the samples were grown on GaAs (001) substrates and without GaAs cap layers. Reflection high energy electron diffraction (RHEED) patterns show clear streaky (1×2) surface reconstruction at $T_s = 220$ °C, and (1×1) surface reconstruction at $T_s = 200$ °C. However, RHEED pattern turned to a shadow when $T_s = 170$ °C. The second phase (hexagonal MnAs) segregation was observed when T_s was above 240 °C.

Temperature dependence of remanent magnetization measured by superconducting quantum interference device (SQUID) magnetometer shows that T_c of the sample grown at 220 °C (sample A) is 105 K before annealing, and can be enhanced up to 165 K after annealing at 160 °C for 16 h (Fig. 1). However, from Fig.1 we can also see that T_c appreciably decreases after annealing time being extended to 40 h, indicating the increase of T_c almost saturates when annealing time is up to 16 h. When annealing temperature is above 170 °C and annealing time is 20 min, a small quantity of the second magnetic phase can be found by SQUID measurements. From these data, we easily find that if the samples are thinner, annealing temperature and annealing time required for obtaining the saturation of T_c are higher and shorter, respectively. Usually, (Ga,Mn)As layer with a GaAs cap layer need longer annealing time to reach high T_c . The sample grown at $T_s = 200$ °C is not a single phase, despite the fact that no obvious second phase can be observed from RHEED patterns. It is obvious that we can grow a single phase (Ga,Mn)As ultrathin films with high x at higher T_s . The effective Mn concentration of the annealed sample A can be deduced to be 0.09 from the magnetic field dependence of magnetization at 5 K (not shown here), lower than the nominal concentration of 0.14. The coercive field is about 25 Oe as much as that of (Ga,Mn)As films with typical thickness ($x < 0.1$) grown on GaAs.

Magneto-transportation has been carried out. The hole density of as-grown and annealed sample A are estimated from Hall measurements to be about $8.4 \times 10^{20}/\text{cm}^3$ and $1 \times 10^{21}/\text{cm}^3$, respectively. The T_c obtained from temperature dependence of sheet resistance is consistent with that measured by SQUID. We also measured the relationship between the Hall resistance and the angle between the current direction and an applied in-plane field of 1 tesla by rotating the sample. As shown in Fig. 2, the in-plane magnetic anisotropy and the anisotropic magnetoresistance exist in as-grown and annealed ultrathin (Ga,Mn)As films, which is in agreement with the results obtained by SQUID measurements [2].

In summary, we have grown a series of (Ga,Mn)As ultrathin films with high Mn concentrations. Magnetization, magneto-transport measurements have been carried out systematically. The highest T_c is 165 K obtained by post-growth annealing. RHEED patterns and SQUID measurements show a narrow growth window for a single phase (Ga,Mn)As ultrathin films with high Mn concentration. The in-plane magnetic anisotropy and the anisotropic magnetoresistance exist in them.

Non-resonant parametric recovery of spin-wave signals.

S. Schäfer, A. V. Chumak, A. A. Serga, B. Hillebrands

Fachbereich Physik und Forschungsschwerpunkt MINAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany

Introduction :

The hybridized dipole-exchange magnonic dispersion spectra of thin magnetic films provide the grounds for storage and recovery of microwave signals by means of parametric interaction of spin waves with an longitudinal microwave magnetic pumping field [1]. Here we report on the non-resonant case of signal restoration when the pumping field frequency is not equal to twice the signal spin-wave pulse carrier frequency. This phenomenon reveals a logarithmic dependence of restored signal powers on the original signal intensity.

Experiment :

As shown in Fig. 1a, the experiment was realized using a thin ferrite Yttrium-Iron-Garnet film placed upon an input and an output antenna with a dielectric resonator between the antennae. A microwave pulse is applied to the input antenna, exciting a traveling spin wave within the ferrite film in the geometry of magnetostatic surface waves (MSSW). This traveling spin-wave pulse is partially converted into exchange dominated perpendicular standing spin waves (PSSW) where both dispersions cross as can be seen in Fig. 1b. After the traveling spin wave left the area between the antennae, a rf pumping field is applied via the dielectric resonator, amplifying the standing waves which transfer energy back to a traveling MSSW which is finally detected as a recovered microwave pulse (see Fig. 1).

Results and interpretation :

In Fig. 2, pulse powers against carrier frequency are depicted for the input pulse (theory, dashed line) as well as the experimental data (circles) and values according to the here presented theoretical interpretation (continuous line) of the recovered pulse. Considering the logarithmic scale, the strong non-linearity between the input signal and the recovered pulse powers is obvious. We interpret this behaviour using the so-called S-theory of parametric interaction[2]. The pumping field generates and amplifies both magnons from the thermal floor (including a so-called dominant magnon group with the highest gain of amplification) and PSSW modes excited by the traveling spin-wave pulse. After the dominant magnons exceed a certain critical threshold, amplification for the other magnons is suppressed. This moment corresponds to the maximum of the recovered pulse. This process of suppression can be understood in terms of a mean internal pumping field generated by all magnon groups, compensating the external pumping [1]. In our interpretation of the experimental data we assumed that not only the intensity of PSSW modes but also the thermal floor level depends on the power of the input spin-wave pulse, since its relaxation provides energy to the magnonic system. Thus the dominant magnon group reaches the critical threshold faster in the case of stronger input signal. This is the reason for the non-linear relation between intensities of input and recovered pulse.

Comparing the input and output power of the experimental setup, it is evident that such a device is suitable for the compression of the input power range, thus increasing the accessible dynamic range of microwave spectral analysis devices.

Reflectivity of microwave signal in ferromagnetic wires.

A. Yamaguchi^{1,2}, N. Higashio¹, K. Motoi¹, T. Kishimoto¹, H. Miyajima¹

1. Department of Physics, Keio University, Yokohama, Japan; 2. PRESTO, Tokyo, Japan

Over the last years, various materials artificially fabricated have received considerable attention both in the fundamental physics and engineering applications. In ferromagnetic materials, their ferromagnetic properties in high-frequency region have attracted much attention since the applications in radio-frequency (RF) devices such as magnetic band pass filters and magnetic integrated inductors.

This study reveals the fundamental physical properties, reflectivity, as a function of frequency, and deals with a 1-D application of a novel concept inspired from a micron-scale line-shaped $\text{Ni}_{81}\text{Fe}_{19}$ wire and a magnetic domain wall (DW) in a boomerang-shaped wire.

The 30nm-thick line-shaped $\text{Ni}_{81}\text{Fe}_{19}$ wire and 50nm-thick boomerang-shaped $\text{Ni}_{81}\text{Fe}_{19}$ wire are patterned directly onto the MgO substrate by means of electron beam lithography and lift-off processing, as shown in Fig. 1 (a) and 1(b). The widths of the line-shaped $\text{Ni}_{81}\text{Fe}_{19}$ wire and the boomerang-shaped $\text{Ni}_{81}\text{Fe}_{19}$ wire were 5000 and 300 nm, respectively. A coplanar waveguide-shaped electrode is comprised of Cr (5nm)/Au (80nm). The device was contacted to a ground-signal-ground (GSG) typed microwave probe. There is no low-frequency cutoff because of the quasi-TEM mode of propagation in our devices. A vector network analyzer (VNA, frequency range: 200 MHz – 20 GHz) was used to inject the RF current into the samples and measure the reflectivity, S11, as a function of frequency. Here, an external magnetic field was applied at an angle of θ from the longitudinal axis of the wires in plane to the substrate. All experiments were performed at room temperature.

Figure 2(a) shows the real part of the impedance ΔZ , which is calculated from the measurement result of the reflectivity, as a function of the frequency and external magnetic field at θ . As shown in Fig. 2(a), we found two ferromagnetic resonance structures. Each resonance frequency is plotted as a function of magnetic field shown in Fig. 2(b). The lower resonance frequency and the higher resonance frequency correspond to the lowest in-plane Damon-Eshbach mode and the lowest perpendicular standing spin wave mode, respectively.

Next, to clarify the reflectivity reflected the microscopic magnetization dynamics in magnetic domain wall in the boomerang-shaped wire. Figure 2(c) and 2(d) shows the simulated pattern of magnetization in the magnetic wire with DW and without DW calculated by OOMMF, respectively. The S11 signals with DW and without DW are displayed in Fig. 2(e). To remove the influence of cables, probes, etc., an on wafer calibration was done for the open-short-load calibration procedure using VNA measurement, the red dashed line corresponds to the calibrated S11 with DW at the absence of an applied magnetic field, which results in the no dip structure in the calibration line. After the magnetic field of 1 kOe was applied at direction in the substrate plane and it was decreased to zero, we measured S11 signal without DW. The black solid line corresponds to the S11 without DW. We find that two dips appear at 9.5 GHz and 10.5 GHz in the S11 signals without DW. This indicated that the precession of the internal magnetic moment within DW depended on the local magnetic effective field because of the internal spin structure of DW. In the other words, the intrinsic resonance of DW has effect on the reflectivity of the wire itself.

We have demonstrated that the reflectivity measurement of ferromagnetic resonance state in the straight line-shaped wire and the DW. We found the spin wave induced by RF signal produced the change of the reflectivity. These results can pave the way to new approaches of signal processing using 1-D spintronics devices.

Ferromagnetic resonance on FeSiB thin films displaying spin reorientation transition.

M. Coisson, F. Celegato, P. Tiberto, F. Vinai
Electromagnetics, INRIM, Torino, Italy

The development of a perpendicular anisotropy in ferromagnetic materials is of great interest because of the perspective applications in data storage. However, even relatively soft magnetic materials that display perpendicular anisotropy are widely studied for fundamental investigations. Moreover, the ability to control a well defined anisotropy in a soft magnetic thin film makes it valuable for ferromagnetic resonance (FMR) studies having both theoretical and applied motivations. FMR studies allow to investigate anisotropy distributions in magnetic materials and magnetisation reversal and damping processes; devices based on such materials can be perspective used as microwave tuners, absorbers or inductors.

In this paper, thin films of nominal composition $\text{Fe}_{78}\text{Si}_9\text{B}_{13}$ have been produced by rf sputtering on Si_3N_4 substrates. Films thickness varies from 25 to 600 nm; in all cases, the materials are amorphous and contain only a minority crystalline fraction, that increases with sample thickness.

Spin reorientation transition (SRT) is observed on the as-prepared samples: when thickness is below a certain threshold (samples 25 and 80 nm thick in our case) the magnetisation lies in the film plane, giving rise to soft magnetic properties characterised by a loop with small hysteresis and a fast approach to saturation. On increasing thickness (samples with thickness equal to 150 nm or above in our case), a perpendicular magnetic anisotropy develops that is clearly reflected in the magnetic force microscopy (MFM) images taken on all studied samples, and reported for a few selected specimens in figure 1. Thinner samples (80 nm thick in figure 1) don't show significant magnetic structures (MFM is sensitive only to the component of the magnetisation orthogonal to the film plane), whereas thicker samples (150 and 600 nm thick in figure 1) develop a clear stripe domain configuration, typical of materials displaying an out-of-plane magnetic anisotropy. The hysteresis loops of these samples, measured by means of a vibrating sample magnetometer, clearly mark the SRT with the appearance of a larger coercive field and a two-phase magnetisation process, with a fast magnetic switching near the coercive field and a slow and almost linear approach to saturation at higher fields. The thickest samples (as the 600 nm thick one) progressively reduce their out-of-plane anisotropy, as marked out by a more irregular stripe domain pattern detected by MFM and by a less pronounced two-phase behaviour of the hysteresis loop.

FMR has been studied on all as-prepared samples with a vector network analyser (VNA) in the frequency interval 40 MHz - 10 GHz. The specimens have been placed face down on a matched coplanar line connected to both ports of the VNA. A reference state is defined by submitting the sample to a saturating magnetic field H_{sat} applied in the film plane. For each applied static magnetic field value H , the ratio $S_{21}(H)/S_{21}(H_{\text{sat}})$ is calculated between the transmission parameters in the current state and in the reference state. Absorption peaks are then detected and their frequency is plotted against the applied magnetic field. Examples are given in figure 2.

SRT is marked by the appearance of a complicated FMR peaks pattern in the studied specimens: thinner films (80 nm thick sample, in figure 2) display a single FMR peak whose dependence on the applied magnetic field follows the Kittel law for thin films [1]. On thicker samples (150 nm thick film, in figure 2) multiple peaks appear, that evolve with the applied field in complicated ways: existing peaks may merge, and new peaks may appear. Whereas high frequency peaks can still be fitted with the Kittel law for thin films, low frequency ones can not. The thickest samples (600 nm thick specimen in figure 2) display again a single peak behaviour, although in this case it cannot be reproduced by the Kittel formula for thin films.

In conclusion, spin reorientation transition has been observed on FeSiB thin films that pass from an in-plane magnetic configuration to an out-of-plane one on increasing thickness, with a progressive reduction of the out-of-plane anisotropy on the thickest samples. Magnetic force microscopy and hysteresis loops evidence the appearance of stripe domain configurations with perpendicular magnetisation in all but the thinnest films. Ferromagnetic resonance, being dependent on the anisotropy of the material, is strongly affected by SRT: thin specimens with in-plane anisotropy are characterised by a single FMR peak; thicker films with out-of-plane anisotropy develop multiple FMR peaks; the thickest films return to a single FMR peak. The Kittel formula for thin films accounts only for FMR curves of the thinner films and for the high-frequency peaks of the thicker films.

Correlation receiver of below-noise pulsed signals based on the parametric interactions of spin waves in magnetic films.

G. A. Melkov¹, V. I. Vasyuchka¹, V. A. Moiseienko¹, A. N. Slavin²

1. Faculty of Radiophysics, Kiev National Taras Shevchenko University, Kiev, Ukraine; 2.

Department of Physics, Oakland University, Rochester, MI

A correlation receiver capable of receiving pulsed microwave signals having amplitudes substantially below the noise level is proposed and experimentally realized. The device is based on the parametric interactions of spin waves propagating in an yttrium-iron garnet (YIG) film waveguide with dimensions $5.1 \mu\text{m} \times 1 \text{ mm} \times 10 \text{ mm}$ magnetized by the bias field $H = 941 \text{ Oe}$ along the waveguide length. Two wire antennae of the diameter $25 \mu\text{m}$ were situated near the opposite ends of the waveguide at a distance of 6 mm between them. The input pulsed signal of the carrier frequency f_s was supplied to the first antenna while the reference pulsed signal of the same carrier frequency was simultaneously supplied to the second antenna. The correlation signal of the frequency $2f_s$ was received by a dielectric resonator situated in the middle of the waveguide and coupled to an output transmission line [1].

First, we studied experimentally the general properties of the above described correlation receiver. The carrier frequencies $f_s = f_r = 4.715 \text{ GHz}$ and the powers $P_s = P_r = 20 \text{ mW}$ of both the input and reference signals were equal. Using the quadratic detector and oscilloscope we were able to observe the envelopes of both the input signal of the voltage U_s and the reference signal of the voltage $U_r \approx U_s$ (see Fig. 1a and 1b, correspondingly). Both signals were rectangular pulses of the 100 ns duration modulated by a Barker code of the length $N = 3$ (see Fig. 1a, b). Using this code, the input and reference signals were subjected to a binary phase manipulation of 0 or π radians three times during the pulse duration. For instance, the input signal pulse in Fig. 1a during the first (0–33 ns) and second (34–67 ns) time intervals had the phase of the carrier equal to zero, while during the third (68–100 ns) time interval it had the carrier phase equal to π . The reference signal was inverted in time, i.e. modulated by the sequence $(\pi, 0, 0)$. The small ($\leq 0.8 \text{ dB}$) variations of the power of the input and reference pulses observed at the moments of phase manipulation are caused by the non-ideal performance of the phase modulators.

Fig. 1c shows the envelope of the output correlation signal having the carrier frequency of $f_{\text{out}} = 9.43 \text{ GHz}$ and peak power of $50 \mu\text{W}$. The experimentally measured magnitude and shape of this output pulse agree well with the results following from the theory of nonlinear interaction of two contra-propagating spin wave packets developed in this work.

Second, we investigated the possibility of reception of a weak pulsed signal on the background of a strong noise using the above described correlation receiver. In this experiment we supplied to the first input antenna not only the pulsed signal of the power 1.4 mW modulated by the Barker code (see Fig. 1a), but, also, a continuous noise-like signal of the power 14 mW , so that the signal-to-noise ratio (SNR) was equal to 0.1. The noise-like signal had a Gaussian profile, and its spectral width was exceeding 200 MHz . The envelope of the combined input signal is shown in Fig. 2a, and it is clear from this Figure that, due to the small signal-to-noise ratio, the pulsed input signal is not noticeable on the noise background. The reference signal supplied to the second antenna had the shape similar to the one shown in Fig. 1b and power $P_r = 7 \text{ mW}$. The envelope of the output correlation signal ($P_{\text{out}} = 3 \mu\text{W}$) is shown in Fig. 2b. As a result of correlation of the combined input signal with the pulsed reference signal the SNR in the output signal increased by more than 20 dB and became larger than 10.

1. Electrical and Computer Eng., Northeastern University, Boston, MA; 2. RF communications Groups, Draper Laboratory, Cambridge, MA

Antennas have been the critical components in radars, satellites, navigation systems, etc., which are crucial for the US Navy, DOD, as well as civilian applications. Compared to other components, antennas have been more resistant to orders-of-magnitude size reduction without drastic degradation in performance. Novel approaches are needed to improve the performance and reduce the size and signature of antennas with significantly enhanced bandwidth, high efficiency, and tunability for multifrequency and multiband operations. Smaller physical size, wider bandwidth, higher efficiency and tunability are desired characteristics of antennas for mobile systems. Antenna miniaturization can be achieved by printing a patch antenna over a high-permittivity substrate. However, the strong capacitive coupling between the antenna and the antenna's ground plane severely degrades its efficiency and bandwidth. To overcome this problem, antennas substrates with relatively permeability > 1 need to be used [1]. However, it has been challenging in achieving self-biased magnetic materials with a high permeability and low loss at RF and microwave frequencies suitable for antenna applications. There has been no report on self-biased magnetic antennas at GHz range.

Bulk ferrite materials, composites of ferrite particles in polymer matrix, metamaterials with embedded metallic circuits, etc., have been used as antenna substrates for achieving $\mu_r > 1$. However, these antenna substrate approaches are too lossy to be used at frequencies > 500 MHz, and large biasing magnetic fields are needed for ferrite materials in antenna substrate. In order to be practically feasible in miniature antenna applications, it is important for antenna substrates to be comprised of self-biased magnetic materials, in which no external bias field is applied.

Microwave magnetic thin films provide a unique opportunity for achieving self-biased magnetic patch antenna substrates with $\mu_r > 1$ at GHz frequency range. The strong demagnetization field of magnetic films allows for high ferromagnetic resonance frequencies up to several GHz and self-biased magnetization as well, which are essential for microwave magnetic devices. We propose to use novel magnetoelectric composite substrates for antennas with low-loss magnetic film materials and low-loss high permittivity dielectric materials.

Our research has led to new designs of electronically tunable self-biased patch antennas with magnetic metallic magnetic films and ferrite films. As shown in Fig. 1 and 2, we have achieved self-biased antennas at 2.1 GHz with a CoFeB film showing large tunability [2]. In addition, we have achieved self-biased antennas at 1.7 GHz and at 2.1 GHz with high quality self-biased ferrite films, as shown in Fig. 3 and 4. This is the first demonstration of electronically tunable self-biased magnetic patch antennas with enhanced performance at GHz.

On the study of left handed coplanar waveguide zeroth order resonator on ferrite substrate.

M. A. Abdalla, Z. Hu

School of Electrical and Electronic Engineering, University of Manchester, Manchester, United Kingdom

1-Introduction:

In the past few years, there has been a great interest in using left handed materials (LHMs) in microwave circuit applications due to their unique properties. The LHMs have been realized in different planar versions [1-3]. As a consequence, many novel planar LH microwave components have been proposed for various microwave applications. Ferrite medium has nonreciprocal and tunable properties. Therefore, tunable and nonreciprocal LH transmission lines (TLs) are expected on ferrite substrate as presented using microstrip TL [4] and using CPW TL [5].

In this paper, we propose a tunable and compact left handed gap coupled line resonator in coplanar waveguide configuration. The proposed resonator is studied analytically and its performance has been verified numerically for different DC magnetic bias.

2-Theory:

A novel LH transmission line resonator has been introduced as an application of the left handed transmission line theory. The principle of its operation is based on cascading a LH TL and a conventional one, right handed, and terminating them by either a short or an open circuit [6]. The total phase shift at the resonator end is the sum of phase shifts introduced by the two transmission lines. A zeroth order LH TL resonator has zero propagation constant due to the phase compensation of both sections. Thus, it can achieve zero electric length at a certain finite microwave frequency with small size. A gap coupled LH TL zeroth order resonator is introduced in [6].

In our work, the proposed resonator is designed by cascading a left handed unit cell transmission line by a right handed one on ferrite substrate in coplanar waveguide configuration. The two cascaded transmission lines are coupled to output and input ports through a small coupling air gap capacitor. An external DC magnetic bias (H_0) is applied horizontally to the ferrite substrate inducing an internal magnetic field. This magnetic field causes the ferrite substrate to have the substrate magnetization (M_0) in the same direction.

3- Numerical Results:

The proposed resonator has been analyzed numerically using the full wave electromagnetic simulation. The commercial software ANSOFT-HFSS is employed.

The performance of the proposed resonator in the case of a applying a dc magnetic bias of 1250 Oe is shown in figure 1 where the resonance frequency is at 3.9 GHz. The performance of the proposed resonator in the case of a applying a dc magnetic bias of 2000 Oe is shown in figure 2 where the resonance frequency is at 4.4 GHz. It is clear that the resonance frequency can be tuned by changing the applying DC magnetic bias. Also, the proposed resonator can suppress the higher order frequency harmonics.

4- Conclusion:

An air gap coupled line tunable zeroth order LH resonator on ferrite substrate has been presented. The results show that the proposed resonator has a tuning capability by varying the DC magnetic bias. The proposed resonator has the advantage of its compact size. Also, it can be applied in many filters and oscillators.

Observation of bright and dark spin wave envelope solitons in periodic magnetic film structures.

A. Ustinov, N. Grigorieva, B. Kalinikos

Physical Electronics and Technology, St.Petersburg Electrotechnical University, St.Petersburg, Russian Federation

Periodic magnetic film structures (PMFS) first have attracted a close attention decades ago [1-3]. Recent years renewed interest to such structures that is stimulated by fundamental and applied investigations of nanostructures, magnonic crystals, and other metamaterials (see e.g. [4,5]). One of the focus areas for periodic structures is nonlinear wave dynamics, in particular, solitonic phenomena. Years ago, gap solitons have been theoretically predicted for “magnetically modulated” ferromagnetic films [6]. At the same time, solitonic effects in PMFS have never been experimentally studied.

This work reports the first observation of envelope solitons in PMFS. Two types of spin wave (SW) solitons, bright and dark, were generated through induced modulation instability (IMI) process [7]. Many ways could be exploited to fabricate planar PMFS. In this work, the PMFS was made utilizing metal strip grating placed onto a single-crystal yttrium iron garnet (YIG) film surface. The grating had a period of 171 μm and consisted of 16 copper strips, each one of 14 μm in width.

The experiments were done on a magnetostatic backward volume wave delay line made with a long and narrow 9.8 μm thick YIG film “waveguide”. The in-plane bias magnetic field was 1220 Oe. The signals were excited and detected by input and output transducers separated by a distance of 10 mm. The grating was centered between the transducers. The soliton experiments were preceded with the measurements of the amplitude versus frequency characteristic (AFC) of the structure. The AFC recorded in a linear regime is shown in figure 1. Note that the position of the first stop-band (“gap”) is well matched with the frequency of the main Bragg resonance that is due to the SW diffraction effect. It should be emphasized that the physical origin of this gap is quite different in comparison with the dipole-exchange gaps appearing in the ferromagnetic film spectrum where the first experiments on SW envelope solitons and modulational instability have been performed [8]. To study the generation process of solitons in detail, the carrier frequencies and amplitudes of the input microwave signals were systematically varied. The main attention was concentrated on the soliton formation in the vicinity of the gap. It turned out that bright solitons were formed on the left slope of the gap whereas dark solitons were formed on the right slope of gap. The frequency zones for bright-soliton and dark-soliton formation are indicated in Fig. 1 by arrows A and B, respectively. Figure 2 gives representative bright and dark soliton train profiles (left panels) together with their power spectra (right panels). Pairs of the input cw driving frequencies were set 5204 and 5206 MHz for bright-soliton generation, and 5211 and 5213 MHz for dark-soliton generation, respectively. The incident microwave power levels were 21.1 and 12 dBm, and 19 dBm and 16.3 for bright-soliton and dark-soliton cases, respectively.

In accordance with the IMI mechanism, time distance between the neighbouring solitons in each train was determined by the beat frequency of the two input cw signals. In both cases of the bright-soliton and dark-soliton generation it was possible to change the observed soliton train periods for about 10 % through adjusting the values of driving frequencies.

In order to give a physical interpretation to the experiment, a theory of SW spectrum for periodically metallized magnetic film was developed. On the basis of the obtained SW spectrum the dispersion and nonlinear response coefficients of the nonlinear Schroedinger equation (NLSE) were

determined. Calculations showed that the NLSE theoretical model with a nonlinear damping term gives a good explanation of the experimental results.

Measurement System of FMR Linewidth ΔH_ω of Ferrite using a Shorted Stripline.

S. Takeda¹, H. Suzuki²

1. Magnontech, Ltd., Kumagaya, Japan; 2. KEYCOM Corp., Tokyo, Japan

Introduction

The measurement method of FMR (Ferromagnetic resonance) linewidth ΔH for microwave ferrite is specified in the international standard¹⁾ of IEC60556. This belongs to resonant method using cavity and is based on perturbation theory. This has some advantages like having a high sensitivity and being suitable for smaller size of specimen. However, there are some drawbacks like; not suitable for narrower ΔH and large size of specimen due to collapse of perturbation approximation. Another big issue is a cost problem. If we want to cover wide frequency range, we have to prepare many cavities with different size because one cavity can measure it only at one frequency. The alternative non-resonant method using a shorted transmission line was already proposed by Bady²⁾. Unfortunately, this method is based on usage of analog network analyzer and contains several theoretical ambiguities. In this paper, we propose a new measurement system based on vector network analyzer, using a shorted stripline similar to Bady's method. This enables us to measure narrower ΔH for larger size of specimen over wide frequency range. And also the measurement of ΔH_ω is proposed sweeping frequency instead of current ΔH sweeping static magnetic field.

Measurement principle

Fig.1 shows a shorted stripline with a square slab shape of specimen. A disk shape is also available. The static magnetic field H_{ext} is applied perpendicularly to the plane of specimen. This situation is modeled by the equivalent circuit of Fig.2, where L_0 is an air core inductance. When a specimen is loaded, it is considered that the portion of η of L_0 is replaced by specimen's complex permeability $\mu = \mu' - j\mu''$ where η is a coupling coefficient. Here, Z_{i0} and Z_{i1} are input impedances of shorted stripline without and with specimen, respectively. Monitoring S_{11} s correspond to them, we can derive a value proportional to imaginary part $\eta\omega\mu''L_0$ of impedance occupied by specimen even if η and L_0 are unknown. A half linewidth is obtained from this FMR absorption curve. When frequency is constant, ΔH is measured sweeping static magnetic field H_{ext} . On the other hand, when H_{ext} is constant, $\Delta\omega$ is measured sweeping frequency. If half linewidth $\Delta\omega$ is enough smaller than resonant frequency ω_r , the relationship of $\Delta H(\text{Oe}) = \Delta\omega(\text{MHz})/2.8$ will hold approximately. The value of ΔH obtained by sweeping frequency is different from current ΔH , so we'd like to call it ΔH_ω . On the same time, Gilbert relaxation constant α and relaxation time τ are calculated by $\alpha = \Delta\omega/(2\omega_r)$ and $\tau = 1/(\omega\alpha)$.

Measurement system

We adopted to measure not ΔH but ΔH_ω under constant magnetic field of permanent magnet. In order to apply H_{ext} perpendicularly to the specimen plane accurately, this system has a fine tuning mechanism rotating a specimen plane and a field direction, monitoring FMR resonant frequency to get lowest. The situation without specimen, namely $\mu' = 1$, was realized by applying a strong magnetic field (5kOe) to specimen parallel to rf field. In case of slab specimen, a higher order ($n \geq 3$) MSW modes are always observed together with main peak. So the absorption curve of μ'' of main peak is not symmetrical left and right. To reduce this influence, the half linewidth of $\Delta\omega$ is derived by doubling a half value only at lower frequency side.

Measurement example

In Fig.3, the relationship between ΔH_ω and dimension ratio (t/L) is shown for 5mm square and 10mm square garnet measured at 2.24GHz, where t is thickness and L is side length of square slab.

To be smaller dimension ratio tends to be slightly narrower ΔH_ω . Thus ΔH_ω is affected by shape and surface roughness of specimen.

Conclusion

By this system, any fine differences of ΔH_ω less than 50Oe of garnet can be measured. We believe this method would become a powerful tool to develop low loss garnet to improve insertion loss and intermodulation of circulator and isolator. Furthermore, saturation magnetization $4\pi M_s$ of garnet is also calculated by ω_r and H_{ext} . This is also available for quality control in garnet manufacturing line.

On the study of ferrite coupled coplanar waveguide.

M. A. Abdalla, Z. Hu

School of Electrical and Electronic Engineering, University of Manchester, Manchester, United Kingdom

1- Introduction:

Recently, a pair of axially magnetized Ferrite Coupled Lines (FCL) structures has been used for nonreciprocal devices at millimetre wave frequencies. The FCL has been proposed experimentally for the first time in [1]. The analysis of the FCL was explained by using either the coupled mode approach [2] or the normal mode approach [3]. Later, novel microwave nonreciprocal devices such as circulators [4], gyrator, and isolator [5] based on the use of FCL sections were constructed. In all previous work, the FCL section was implemented using finline, microstrip, stripline, or slotline configurations. The coplanar waveguide structures have many attractive features in microwave applications.

In this paper, we introduce, for the first time, an FCL junction in coplanar waveguide configuration. The design of the proposed FCL section is done within the general FCL principles and the different performance properties of the proposed FCL have been verified numerically using full wave electromagnetic simulation results. Nonreciprocal CPW devices can be designed as applications of the proposed CPW FCL section.

2-Theory:

The proposed structure is realized by putting two closely spaced parallel lines on ferrite substrate which is longitudinally magnetized. The vertical cross section and the longitudinal cross section of the proposed CPW FCL structure are shown in figure (1-a and b) respectively.

In our work, the design objectives of the CPW FCL is to have centre frequency in the frequency band 5-11 GHz and its two input impedances at its ports matches to a 50 ohm CPW feeding transmission lines. These design objectives are fulfilled by the full wave numerical solution of the proposed structure through the parametric studies of the different circuit geometry parameters to satisfy the propagation requirements of a typical FCL performance.

3- Numerical Results:

The proposed structure has been analysed using the full wave simulation. The commercial software ANSOFT-HFSS is employed.

The scattering characteristics of the proposed FCL CPW junction for excitation at port 1 are illustrated in figure 2. It is shown that the structure reacts as a forward coupler whose scattering transmission coefficients S21 and S41 are better than 5 dB level in the frequency band from 7-11 GHz. Similar results can be obtained for the case of excitation port is port 3.

The phase difference between the two outputs in both excitations at port 1 and 3 is illustrated in figure 3. For the case that the excitation is at port 3, the phase difference varies around 0 degree while for the case where the excitation is at port 1, the phase difference varies around 180 degree. In both cases, the maximum variation in the phase does not exceed few degrees.

The former power division results with the latter phase results of the forward coupler confirmed the even/ odd modes output on changing the excitation port of the FCL junction which is a unique property of the FCL junction.

4- Conclusion:

A novel CPW FCL has been proposed. The performance of the proposed FCL is optimized numerically. The unique features of the proposed FCL have been verified to agree with the theory of the FCL. The proposed FCL has a wide frequency band.

The application of manganite layers to functional devices, such as magnetic tunnel junctions (MTJs), has been hindered by the negligible room-temperature tunnel magnetoresistance (TMR) observed in the junctions fabricated so far. It is remarkable that the majority of manganite-based MTJs uses (001) pseudocubic substrates and, interestingly, much less attention has been devoted to other orientations. However, the drawbacks of (001) oriented electrodes are well documented and have been extensively studied and attributed to the intrinsic tendency of manganites to develop electronic inhomogeneities [1], which are localized in the proximity of the interface with the substrate [2]. Thus, the functionality of the (001) oriented MTJs is much affected by the high sensitivity of (001) electrodes. Although high values of TMR have been obtained at low temperature, the TMR temperature dependence decays at lower temperature than the Curie temperature (TC) of (001) manganite electrodes [3]. The occurrence of spin depolarization at the (001) interface has been argued to be the cause of this decrease in the TMR. With the aim of contributing to better understanding and solving these problems, we have studied the effect of the atomic plane of growth in single manganite layers and heterostructures. With this purpose, we have used the same cubic substrate for the epitaxial growth but with two orientations: (001) and (110).

Epitaxial La₂/3Ca₁/3MnO₃ (LCMO) films of different thickness have been simultaneously grown on SrTiO₃ (STO) substrates with (001) and (110) orientation. From unit cell parameters of films in a wide range of thickness and from their magnetic properties we have investigated the effect of the crystal deformation on the TC. A first result signals the different magnetization dependence on temperature (Figure 1a) which appears at any given thickness, being the magnetization and the TC of (110) films always higher than that of (001) ones. Using the Millis magnetoelastic model [4] to analyze our data, we deduce that the TC of highly strained (001) films do not follow that model. On the contrary, less strained (110) film data fit nicely to the magnetoelastic model. Although the resulting dependencies of TC on strain can be partially related to biaxial strain, we conclude that the strong reduction of the TC on (001) films cannot be directed uniquely by this contribution but other causes may be at the origin. Thus, using ⁵⁵Mn nuclear magnetic resonance (NMR), electron energy loss spectroscopy (EELS) and X-ray photoemission spectroscopy (XPS) we have investigated the electronic state of Mn ion through the films (by NMR) and the chemical composition of the films (by EELS) and that of film surface (by XPS). From these experiments, electronic phase separation and Ca segregation to the surface have been observed in (001) films, whereas (110) films are fully electronically and chemically homogeneous [5].

These experiments lead to conclude that LCMO layers could become better electrodes for MTJs and also serve to understand the physical origins of the observed electronic and chemical effects in bare films. We have also grown epitaxial bilayers of STO/LCMO//STO with (001) and (110) orientation and tuned the barrier thickness in the range of 2 to 5 nm, fixing the LCMO layer thickness

to 25 nm. Structural characterization of these samples show that the STO capping layer does not contribute to change the strain of the LCMO unit cell for both (001) and (110) orientations. Magnetic properties of (001) and (110) bilayers present a different evolution when compared to their electrodes counterparts. Most remarkably, we observe (Figure 1b) an important decrease of the magnetization in (001) bilayers compared to that of (001) electrode, whereas the (110) bilayer magnetization remains almost unchanged as that of the (110) electrode. With NMR, EELS and XPS experiments we have found an evolution of the electronic phase separation and chemical redistribution in the (001) STO capped electrodes, whereas neither electronic nor chemical inhomogeneities are observed in (110) films.

We discuss these results on (001) and (110) LCMO electrodes and STO/LCMO bilayers in the framework of the promotion of carrier localization in (001) planes which can be related to the different polarity and elastic properties in (001) and (110) LCMO layers.
